Under these circumstances all other allied or similar diseases, such as the several non-specific forms of peripheral neuritis, Raynaud's disease, and the analgia, Morvan's disease, syringomyelia, syphilis, sclerodactylia and tuberculosis should be excluded by differential diagnosis before these two cases (sisters) are entitled to be classed among the examples of indigenous leprosy of the United States. It is admitted that there is much to be said in favor of the view that these cases are actually lepra, but the history and the symptoms are so unusual that the reader of the paper who may be interested in that disease is disposed to ask for more facts, and especially for the points in differential diagnosis, together with the results of bacteriologic examination for the bacillus lepre.

Cases of leprosy occurring in infants and children who have been born in this country, and who have not been in any way exposed to known lepers, are so extremely rare as to be worthy of the fullest possible account of them that can be given. Indeed, it may be stated that the writer knows of no such cases heretofore recorded.

As illustrating rare or undescribed forms of disease simulating lepra, the case figured and reported by E. von Düring, of Constantinople, in the "International Atlas of Rare Skin Diseases," plate xxxi, may be referred to. The patient was a boy 6 years old, the morbid process being characterized by a kind of myxomatous swelling of the first and second phalanges of the fingers and complete absorption of the terminal phalanx. All ten fingers were involved. The terminal phalanges of the two middle fingers, of the left index finger, and the fourth finger of the left hand were completely absorbed. A sclerosed ring encircled the middle of the second phalanx of the right index finger. The bones of the other fingers were thickened and the soft parts extremely indurated. The nails on the absorbed phalanges had shrunk to small and thickened plates. The reporter of this case named the disease "sclerodactylia annularis aninhumides." Leprosy was excluded.

Respectfully,

LOUIS A. DUHRING, M.D.

### The Practice of Medicine Act in Congress.

DR. S. C. BUSEY TO THE COMMISSIONERS.

WASHINGTON, D. C., February, 1895.

Honorable Commissioners of the District of Columbia.

Gentlemen:—I am instructed by the Committee on Legislation of the Medical Society of the District of Columbia, to communicate to your Honorable Board the objections of said committee to several provisions of the bill, known as the "Commissioners' Bill," and entitled, "A bill to regulate the practice of medicine and surgery, to license physicians and surgeons, and to punish persons violating the provisions thereof in the District of Columbia."

The committee of the Medical Society suggests that Sec. 1 be so amended that not more than two of the Board of Medical Supervisors shall be appointed from either of the three systems of medicine recognized in the bill, so that it will be impossible for either of these systems of medicine to acquire a majority of said Board of Medical Supervisors.

The committee recommends the omission of all of Sec. 3 after the word "surgery" in line 30. This clause provides for the licensing of "any applicant intending to practice in the District of Columbia any system of medicine or treatment other than the regular or homeopathic or eclectic system," and is objectionable not only because it is an invitation to the horde of charlatans, pretenders and impostors driven from the States by the enforcement of medical practice laws, which prevent the prosecution of their nefarious and mercenary impositions, to settle in this District, now the common rendezvous of such disreputable classes, but it is a direct and positive insult to every intelligent and educated physician, in that it ignores all and every method and system of preliminary and technical education, and is in direct conflict with the reforms and elevated standard of medical education which the profession is putting in active operation throughout the country. There is now in this city one system claiming to have a charter under the provision of the general incorporation law, with one emeritus professor, and one graduate who signed the certificate of his own graduation. Under the clause referred to, unlike systems but similar institutions may be chartered at the will of any drug or medicine fiend, and be entitled to a license to practice the science of medicine in this District.

The same clause of Sec. 3, lines 45 to 47, compels such applicant, when licensed, to insert "in any advertisement he may cause to be displayed, the designation of the system of medicine or treatment employed by him for the cure or relief of disease." Thus, not only is the fraud to be licensed, but when licensed, he is required to commit a fraud upon the credulous public by advertising to do that which he knows he can not do.

The third objection to the "Commissioners' Bill" refers to the omission of any provision prohibiting "publicly advertising ability to treat and cure diseases," as is usual in medical practice laws. Such a prohibition would banish from this District every such disreputable pretender, and protect this community from that class of frauds and impostors driven from the States and territories. It is idle to claim that such result can be accomplished by the enforcement of the rules, regulations and codes of medical ethics, when only such persons can be made amenable to such rules and codes as may have acquired membership in ethical organizations. The advertising charlatan has no code but that of fraud and criminal deception.

The Medical Society of the District of Columbia is willing to accept any one of the forty medical practice laws now in force in the States and territories of the country, except the Alabama law, to which it objects because of a provision somewhat similar to the objectionable clause in Sec. 3, of the "Commissioners' Bill," but which is more securely guarded because of the supervision of the State medical society.

The committee, therefore, requests the Board of Commissioners to so modify the bill S. 2685, known as the "Commissioners' Bill," that it may give to it its unqualified support.

I have the honor to be your obedient servant,

SAMUEL C. BUSEY, M.D.,

Chairman of Committee of the Medical Society of the District of Columbia.

### The Ophthalmoscope in Kidney Disease.

WABASH, IND., Feb. 19, 1895.

To the Editor:—"Advanced kidney disease is often first discovered by ophthalmoscopic examination."

Illustrating the truth of the above item taken from a recent medical journal, I wish to report a case which came under my observation recently:

C. M. was sent to me by Dr. K. to be fitted with glasses. He had been complaining of failing vision for about four weeks in right eye and for two weeks in left eye. Vision was equal to counting fingers at ten feet. No improvement with glasses. Ophthalmoscopic examination showed extensive patches of albuminuric retinitis in both eyes. I then questioned him about his general health, which he said was very good. Had not been sick and felt as well as usual. No trouble with kidneys as far as he knew. I sent him back to his family physician, Dr. K., with a letter, telling him what I had found, and asking him to make a careful examination of the patient's urine for albumen, and to put him on treatment. In a few days I received a letter from the Doctor stating that he had found C. M.'s urine very heavily loaded with albumen. Fifteen days after the first examination I again saw the patient, and he was still feeling about the same. Vision in right eye was equal to counting fingers at five feet, and in left eye to counting fingers at ten feet. At this time I am satisfied he would have been accepted as a good risk by any life insurance company that did not require an examination of the urine, and many good companies do not. He took his bed shortly after this, developing in a short time all the well marked symptoms of Bright's disease, and died in five weeks from the last examination.

OREN ONEAL, M.D.

### Archiv für Verdauungs Krankheften.

BALTIMORE, MD., Feb. 12, 1895.

To the Editor:—The rise of a specialty in medicine is marked by the appearance of journals especially devoted to it. We are glad to inform you, that the new specialty of "Diseases of the Digestive Organs" is about to have its own publication—the *Archiv für Verdauungs krankheiten* which will appear in April. It will be published in Berlin, Germany, by S. Karger. The editor is Dr. I. Boas, the well-known author of a work on "Diseases of the Stomach." He will be assisted by specialists in Germany and other countries. The *Archiv* will contain original articles, besides reviews and abstracts of recent literature, and will embrace diseases of the stomach, intestine, liver, pancreas and peritoneum, constitutional diseases and dietetics. Those interested may communicate with the editor or the publisher.

Yours, etc.,

JULIUS FRIEDENWALD, M.D.

### To Military and Naval Medical Officers..

To the Editor:—The undersigned, members of the "Committee on Litter," appointed by the Association of Military Surgeons of the United States, to report at the approaching annual session a desirable form of military litter for the comfortable, safe and expeditious transportation of the sick and wounded, solicit from medical officers of the National Services and the National Guard of the several States, suggestions, plans or models of such an appliance, to be delivered to either of them at their respective addresses, on or before the first of April, 1895.

ALBERT L. GIBON, Medical Director, U. S. Navy,  
U. S. Naval Hospital, Washington, D. C.  
JOHN VAN R. HOFF, Major and Surgeon, U. S. Army,  
Governor's Island, Harbor of New York.  
MYLES STANDISH, Capt. and Asst. Surgeon, M. V. M.,  
200 Dartmouth Street, Boston, Mass.

### The Surgical Section.

HARTFORD, CONN., Feb. 9, 1895.

To the Editor:—Will you kindly give me the name and address of the Secretary of the Surgical Section of the AMERICAN MEDICAL ASSOCIATION? Yours truly,

M. M. JOHNSON, M.D.

ANSWER:—Joseph Ransohoff, M.D., 296 Walnut Street, Cincinnati, is Chairman, and Reginald H. Sayre, M.D., 285 Fifth Avenue, New York City, is Secretary. We have printed these names each week since the San Francisco meeting.

## BOOK NOTICES.

**A Manual of Diagnostic Neurology for General Practitioners and Students.** By ALEXANDER B. SHAW, M.D. Illustrated. St. Louis, Mo. 1894.

This little work of 114 pages makes a decidedly favorable impression. It is compact, and at the same time we note that there are no serious omissions in the description of the diagnostic relations of the nervous system. The arrangement of the book is excellent and accentuates the diagnosis of nervous diseases in a manner which will bring them home to the student and fix them in mind in a much better way than they can be obtained from the general treatises on nervous diseases. The first chapter deals with objective symptoms, such as aspect and expression, motor symptoms, ataxia, titubation, rotatory and choreic movements, tremor, and spasm in all its varieties. The reflexes are briefly considered, and we note that the writer does not regard the absence of them as always an evidence of a pathologic condition. In this we would heartily agree with him. It is the loss and not the absence of the reflexes which determine the value of this sign in the pathology of nervous diseases.

The diagram on page 10, showing the reflex centers of the spinal cord, will materially facilitate the regional diagnosis of cord lesions. Page 25 has an excellent diagram illustrating the varied effects of lesions of the motor and sensory paths from the cortex to the periphery. These ought to prove of great value to the beginner in nervous pathology. It is a simplification of the more complicated diagrams which are found in German works and is much easier of comprehension than most of the diagrams of this kind. On page 26 a case of myotonic spasm is reported, which is an exceedingly interesting one, and illustrates well the diagnostic relations of this condition. We doubt, however, the propriety of putting into a work of this kind a purely controversial matter such as that concerning this case.

Throughout the work the author has given us some excellent tables of the differential diagnosis of certain lesions of the nervous system. We would especially call attention to the table relating to the differential diagnosis of paralysis from cortical cerebral lesions and paralysis from non-cortical cerebral lesions. This, and the table showing the points of resemblance and difference between spinal apoplexy, hemato-myelitis, hemorrhage into spinal membranes, Landry's paralysis, acute poliomyelitis, painful paraplegia and acute central myelitis and multiple neuritis, are of especial value. Another table giving the differential diagnosis of monoplegia of central, spinal and peripheral origin, is one that will prove useful.

The writer says that tactile sensibility may be roughly estimated, by touching the part to be examined by the finger or camel's hair pencil, and he gives the preference in testing sensation to the esthesiometer. In our judgment this instrument is of comparatively little value in neurologic work. Better results can be achieved by the use of a small pledget of cotton in determining tactile sensibility and its acuteness, and then by such simple means as varying weights, coins or other well-known objects placed in contact with the skin. These, combined with the use of a pin, will achieve much more accurate results and in less time than they can be reached with the use of the esthesiometer.

The chapters which relate to the diagnostic relations of the optic nerves and the testing of vision, as well as that which deal with aphasia, are exceedingly compact, well written, and contain about all that is of practical importance in the diagnosis of nervous diseases.

On the whole the work is well written; the illustrations are well selected, but many of them are very poorly printed.

While this mars the general appearance of the work, it does not detract from its usefulness. We think that a short chapter on electrical diagnosis would have materially added to the completeness of the work without greatly increasing its size.

## PUBLIC HEALTH.

**Rapid Production of the Diphtheria Antitoxin.**—That section of the report of the Director of the British Institute of Preventive Medicine which deals with the diphtheria antitoxin (London *Lancet*, February 2) is somewhat disappointing in that it contains no reference to Dr. E. Klein's experiments, made for the Medical Department of the English Local Government Board—having for their object a study of the preparation and nature of the diphtheria antitoxin. Last December Dr. Klein claimed to have succeeded in reducing the time necessary for the production of the serum to less than one-fifth that usually consumed, and explained his method as follows: By a few injections of the attenuated living bacilli (the attenuation is due to the age of the culture) along with their toxin into the horse, this animal is furnished with a certain degree of resistance. Next, large quantities of living diphtheria bacilli (minus their toxin) taken from the surface of solid cultures of gradually increasing virulence, are repeatedly injected subcutaneously, so as to allow the bacilli to grow and multiply and to produce gradually within the body of the animal, as is the case in the natural order of things, the toxin and, ultimately, the antitoxin. Every such injection is followed by a temporary reaction, a rise of temperature varying between 0.6 degrees and 1.8 degrees C. and a local tumor; but there is no suppuration at the seat of inoculation. As soon as one such tumor has disappeared a new injection is made, as stated above, with large quantities of living bacilli scraped from the surface of solid media (agar and gelatin). By the third week the animal will bear the scrapings from the surface of two whole agar cultures of virulent character. In the case of one horse, by this method, antitoxic serum was obtained in twenty-three days; in another horse in twenty-six days from the date of first injection. If, after the first bleeding of the horse, it be again twice or thrice injected with virulent living bacilli (taken from the surface cultures) the further serum obtained from such horse possesses even increased antitoxic power. The antitoxic power of the serum in the twenty-three and the twenty-six days' horses was tested on guinea pigs, and it was found that one part of serum was capable of protecting from 20,000 to 40,000 grams body weight of guinea pig against the living bacilli and toxin (not merely against pure toxin), considerably more than a fatal dose of living bacilli having been injected. Dr. Klein says this serum has been used in cases of diphtheria on the human subject—some of them very severe cases. It was injected in doses of from 5 c.c. to 8 or 10 c.c., and in severe cases the injection was repeated within twenty-four hours. The result was highly satisfactory. In some severe cases it was particularly striking, the further spread of membrane being entirely arrested, and rapid loosening and discharge of the existing membrane being also a conspicuous feature.

More than sufficient time has elapsed since Dr. Klein made his method public in which other producers could have tested it, and it is not a little singular, considering Dr. Klein's high scientific standing, that the Institute should have ignored it. Dr. Ohlmacher, Director of the Laboratories of Pathology and Bacteriology of the Medical Department of the University of Wooster, at Cleveland, has succeeded in rendering a horse proof against diphtheria in forty-six days, but his method has not yet been made public, and it is not known whether he has followed Dr. Klein in any degree.

**Decline of Smallpox.**—The steady diminution of the smallpox incidence continues—except in St. Louis, where an Associated Press dispatch of the 20th says there were seventy-two cases in the Quarantine Hospital at noon of the 19th; ten new cases were reported on that day, and the

dispatch adds, "it is thought this number will be greatly increased when full returns are received to-night." Nothing official has been received by the *JOURNAL* concerning this outbreak, information of which is in the nature of a surprise. In Chicago there were eighty-four cases remaining under treatment on the 20th inst.; twenty new cases occurred during the week; eleven localities were under surveillance on that day as against sixty-one one month previous. All known cases are in the Isolation Hospital. During the week ended February 18, there were seven new cases and two deaths in Milwaukee and two cases at other points in the State. At that date there were thirty-six cases remaining under treatment in the city—fourteen in the hospitals and twenty-two in homes, as against forty-three under treatment one week previous—sixteen in hospitals and twenty-seven in homes. Isolated cases continue to occur in other parts of the country and an occasional steamer is quarantined on arrival on account of the disease; but the smallpox "epidemic" of 1894-95 seems to be substantially at an end. This speedy termination of what threatened a year since to be a serious calamity is fairly attributable to more general and effective vaccination than was possible fifteen or twenty years since, and this has been accomplished to a very large extent through the support of the courts which have uniformly sustained the health authorities in enforcing vaccination. The latest instance is that of the Supreme Court of Brooklyn which, on the 16th inst. handed down a decision, in which the Court says: "The prevention of smallpox is of such paramount importance as to justify all reasonable means for its accomplishment. The propriety and wisdom of the course pursued by the [Brooklyn] Board in vaccination is beyond criticism. Its acts have all been within the lines of statutory authority and they have been discreet and in evident good faith in the presence of an impending pestilential danger."

**Water Supply for Boston.**—The Massachusetts State Board of Health, which has had under consideration the question of the water supply for Boston and suburbs, recommends, as a result of its investigations, that the supply be taken from the Nashua River above Clinton. It is proposed to build a dam which will raise the water of this stream 107 feet above the surface of the mill pond at Lancaster Mills, thus constructing a reservoir which will have a capacity of 63,000,000 gallons. It is claimed that the merit of this plan will be its permanent solution of the water problem of the district. Should this supply be inadequate, it will be entirely feasible at a small expense to reach the valleys of the Ware and Swift Rivers, which, with accessions from the Westfield and Deerfield Rivers, will furnish a supply of the best water for a municipality larger than any now found in the world. The Board rejected the only other plans which seemed worthy of critical examination, namely: A supply from Lake Winnipiseogee, and one from the Merrimac River above Lowell. The lake supply was abandoned because the Board thinks it doubtful if the State of New Hampshire would allow the quantity needed to be taken from the lake, to say nothing of the expense of \$34,000,000 for a conduit, and a further sum for damages for diversion of the water. The supply from the Merrimac River would need filtering, and this would involve an investment of \$17,400,000 besides annual cost of maintenance. It is estimated that the total first cost of the Nashua River supply would be about \$19,000,000 and the ultimate expenditure for the full development of the supply from this source, about \$25,000,000 for an average of 173,000,000 gallons daily.

**Cows, Oysters and Typhoid.**—As a result of his recent investigations, Dr. Thorne Thorne is convinced that just as un-boiled milk mixed with typhoid-infected water may dis-

tribute typhoid fever among its consumers, so also the liquid of uncooked oysters may be the means of conveying typhoid fever, if water infected with typhoid fever is imprisoned between the valves of the oyster. He does not believe, however, that either the cow or the oyster can elaborate typhoid fever from sewage, but it is quite possible that oysters may mechanically convey typhoid fever, just as milk mixed with infected water may be the medium for distributing this disease. He thinks that in both cases it is more than probable that the danger is much exaggerated; to which it may be added that a similar exaggeration of the danger of conveying typhoid fever through the medium of sewage-irrigated vegetables is also more than probable—the results of bacteriologic examination of such vegetables, including “sallet stuff,” water cress, lettuce, etc., being thus far entirely negative.

**Malarial Fever in Italy.**—The Italian Bureau of Statistics has recently issued a map of the distribution of malaria in Italy, showing the different degrees of mortality by various tints. From it the *Journal d'Hygiene* learns that in the years 1890-91-92 there were 49,407 deaths, or an average of 54 per 100,000 inhabitants yearly. Along the Mediterranean intense endemic centers of malaria are shown in the Grossetano, in the Pontine marshes, in the Salernitano and in the environs of Pestum. Deaths from malaria are rapidly decreasing in Rome; in 1881 there were 650 deaths from this cause; in 1882, 505; in 1892, 139; in 1893, 189. Malaria is more intense in the Roman Campagna and on the Adriatic coast. A strongly colored zone is shown on the map, beginning at the promontory of Gargano, descending by Molene and ending at Iomo. The disease is still strongly epidemic in Sicily and Sardinia.

**Cholera Precautions.**—Owing to the reappearance of Asiatic cholera in the suburbs of Constantinople, the Direzione della Pubblica Sanita of Italy has increased the stringency of its regulations requiring the medical visitation and disinfection of all vessels coming from the Black Sea, from the colonial French ports, from those of Russia and of Roumania on the Danube, from the Sea of Marmora, from the Aegean and from the North African littoral (excluding Tripolitania) and from Brazil. The Argentine government has formally recognized the existence of cholera in the Confederacy.

**A Yellow Fever Congress.**—It is proposed to hold a Congress on yellow fever during the Cotton States and International Exposition at Atlanta. The plan proposed is that the leading physicians of the city invite the leading physicians of the South Atlantic and Gulf cities, with a view of securing concert of action on quarantine measures and methods of dealing with the disease.

## SOCIETY NEWS.

**The St. Louis Medical Society** held a regular meeting February 9.

**The Lehigh Valley Medical Society** held a regular meeting February 12.

**The Lackawanna County Medical Society** held a meeting February 12.

**The Atlantic County Medical Society** held its annual meeting at Atlantic City February 6. The following officers were elected: President, H. C. James; Vice-President, Philip Marvel; Secretary, E. L. Reed.

**The New York State Medical Society** concluded its session February 7. The following officers were elected for the ensuing year: President, Roswell Park, of Buffalo; Vice-President, Wm. Maddren, of Brooklyn; Secretary, F. C. Curtis, of Albany.

**The Arizona Medical Association.**—The fourth annual session of the Arizona Medical Association convened at Phoenix, Ariz. February 6. The following officers were elected for the ensuing year: President, Dr. P. G. Cotter; Vice-Presidents, Drs. Neil McIntyre, B. G. Fox and A. M. Givens; Secretary, Dr. L. D. Dameron; Treasurer, Dr. I. B. Hamilton; Essayist, Dr. F. H. Willes. The next meeting will be held in Prescott, May 28, 1896.

**The Obstetrical Society of Cincinnati** at its annual meeting elected the following officers for the ensuing year: President, Dr. A. W. Johnstone; Vice-President, Dr. Sigmar Stark; Secretary, Dr. E. S. McKee; Corresponding Secretary, Dr. W. D. Porter; Treasurer, Dr. G. E. Jones.

## SELECTIONS.

**Treatment of Senile Heart.**—In his recently published work on “The Senile Heart,” Dr. G. W. Balfour thus summarizes his method of treatment: *Precordial anxiety*—careful dieting; cardiac tonics; rest at first, afterward regulated exercise. *Intermission and irregularity*—careful dieting; vascular stimulants, combined with cardiac tonics; sedatives, especially for women about their climacteric, occasionally hypnotics; antacids and anti-arthritis; assafetida (pil. galbani co.); moderate exercise. *Palpitation*—antacids; stimulants; mustard over precordial region; hot foot-baths. In interval strengthen patient by open air exercise, good food and such tonics as may seem needful, especially iron. *Treatment cordis*—careful dieting most important; antacids; anti-arthritis; pil. galbani co. *Tachycardia*—careful dieting; in recent cases following cardiac overstrain, belladonna or atropin must be pushed till pupils dilate. In cases of poisoning by tobacco or alcohol, tonic doses of digitalis useful. Cardiac tonics, especially digitalis and arsenic, continued for a long time in moderate doses, supplemented by hypnotics at bedtime especially morphia. Digitalis most useful in vagus paralysis, morphia in affections of the sympathetic. Cholate of soda slows the pulse, but it destroys the blood corpuscles, and the benefit is thus a doubtful one. Antipyrin has been recommended theoretically. Faradization of the skin over the precordia, or of the vagus nerve; or the skin or vagus may be galvanized. Compression of the vagus. Forced inspiration, holding the breath as long as possible. Ether sprayed along the cervical spine. A chloroform poultice over the precordial region. *Bradycardia*—in the hemi-systolic variety, cardiac tonics, especially digitalis. In true bradycardia, digitalis is also indispensable, to maintain the elastic tonicity of the heart, and to enable the heart to cope with the exceptionally high blood pressure prevalent during part of the systole. *Delirium cordis*—careful dieting; vascular stimulants, cardiac tonics, antacids, and anti-arthritis. *Angina pectoris*—during the paroxysm, nitro-glycerin, nitrite of amyl, chloroform and morphia, during the interval most careful and abstemious diet, especially towards evening. Vascular stimulants in combination with cardiac tonics, especially arsenic. Exercise is to be avoided, and only undertaken when duly prepared for by the ingestion of some vascular stimulant.

## NECROLOGY.

JAMES BURNS, M.D., Louisville, Ky., on the 11th inst. Dr. Burns was born in Dayton, Ohio, Nov. 15, 1820, and was in his seventy-fifth year.—William T. McGinnis M.D., of Eminence, Ky., February 13. Dr. McGinnis was a graduate of Center College and of the Louisville Medical College.—L. C. Wagner, M.D., of Nicholasville, Ky., February 14.

WILLIAM GODFREY DYAS, M.D., of Chicago, was instantly killed by a railroad train February 17. He was born in Dublin, 1807. At the age of 16 he entered Trinity College, Dublin. From thence he was transferred to the Royal College of Surgery, where he was graduated in 1830. In 1832 he received an

appointment to the cholera hospital, County Kildare, which was under the supervision of the government. At the closing of this hospital he was placed in charge of the fever hospital, and also three dispensaries. In this extensive field of practice he labored for a period of twenty-five years, when on the approach of the potato famine and its final consequence, he returned to Dublin, and was appointed Assistant Demonstrator of Anatomy at Trinity College. A year later (1856) he came to America; in July, 1859, he moved to Chicago and for some months was editor of the *Chicago Medical Journal* under the late Dr. Brainard. He was President of the Cook County Medical Society for the year 1873-74. He was one of the prime movers in the establishment of the Woman's Medical College.

## MISCELLANY.

**Diphtheria-Serum.**—Dr. Ohlmacher, of Cleveland, writes us that with the coöperation of Drs. C. B. Parker and H. W. Kitchen, all of Cleveland, he has completed the immunization of a horse against diphtheria. The time occupied was one month and sixteen days. He has verified the immunization by repeated tests and is of opinion that this is the first diphtheria immune horse in the United States.

**Protection from Facial Paralysis.**—Chabbert (*Le Progres Medical*) thinks the protection afforded by the hairy covering of the face plays an important rôle in the prevention of facial paralysis *a frigore*. The influence of this factor explains why facial paralysis is much more common in women than in men, and why in the male sex we notice it more frequently in those with smooth faces. The beneficial influence of the beard on tri-facial neuralgia has already been pointed out.

**Diagnostic Import of Premature Expulsion of Meconium.**—Rossa observes that premature expulsion of meconium is generally supposed to indicate danger to the fetus from asphyxia, and is consequently a reason for hastening delivery. The author (*Arch. f. Gyn.*) thinks this is an error and has shown that it is not true in a large number of cases. In his opinion it is due to increased peristaltic movements in the fetus, which may depend on a number of causes other than asphyxia. Among these causes Rossa insists on those of maternal origin—gastro-intestinal among other.

**Ice-Chloroform.**—J. Christian Bay, F.G.B.S., Bacteriologist to the Iowa State Board of Health, is pursuing investigations into the mortiferous poisons of chloroform, and asks that samples of long-preserved chloroform and other fluid chemicals containing whitish flocks or precipitates be sent him for examination. He claims to have found in chloroform which had caused death, certain chemie products of the putrefaction of the anesthetic. Following in this line the investigations of Dr. René Du Bois-Reymond, Mr. Bay says that these poisonous products may be removed by crystallization in ice, and that such ice-chloroform presents the only security against danger from a long kept specimen.

**Excito-Motor Power of the Stomach in the Insane.**—G. Dotto furnishes the results of his experiments to determine the excito-motor power of the stomach in the insane—*Arch. di Farmacol.* The betol test was used in patients not receiving any other medicament. Two hours after the ingestion of one-half liter of milk, one gramme of betol was given and the acidulated urine was tested with ether for the first traces of salicyluric acid. The researches of Lovisetti, Fodera and Corselli prove that the betol test is better than that with salol and more practical than Leube's test. Apart from special lesions the excito-motor power is normal in

arrested psychic development (idiocy), diminished in hysterical lethargy, increased in those forms of mental alienation with psychic and motor excitation, and but little increased in cases of psychic depression.

**Ablation of the Mammary Gland.**—Horner gives the results obtained in 172 cases of malignant tumors of the breast treated by amputation—*Beitr. z. Klin. Chir.* Of this total number of cases, 158 were cancerous in nature. The operation itself caused 5.9 per cent. of deaths. The mean duration of life was eighteen and eight-tenths months more in these 172 cases than in those not operated upon. Horner adds that there were 17.7 per cent. of definite recoveries—that is to say, with no return of the disease after more than three years. These statistics include fourteen cases of sarcoma, the average age of the patients being a little over 39 years. Thirteen of these patients had a total of seventeen operations performed; of this number there were ten recoveries, a mean of 76.9 per cent.

**Function of the Suprarenal Capsules.**—Some light is thrown upon the nature of the function of the suprarenal capsules by a series of experiments made by De Dominicis. He concludes (*Arch. de Phys.*) that total extirpation of these bodies, either simultaneously or with an interval between, invariably causes death after a maximum lapse of two, three or four hours. This ablation immediately causes intense shock, with phenomena of stupefaction and of general collapse, especially of the heart. Section of the spinal cord in advance, or the exhibition of atropin, notably retards these symptoms, and at the same time diminishes their intensity. The theory of auto-intoxication appears to De Dominicis less in accord with these facts than with that of a violent neurolytic action, thus apparently confirming the recent opinion of Fusari that the suprarenal glands are nervous ganglia.

**Harvard Medical School.**—The resignation of Prof. H. P. Bowditch from the office of Dean of the Harvard Medical School, after a period of service extending over ten years, is made the occasion for a review of the progress made by the School during that time in the annual report of the President and Treasurer of the Harvard College. In 1883-84 there were 243 medical students; in 1893-94 there were 472 in attendance. During the same period the number of the faculty has increased from twenty-two to twenty-eight persons, and that of the instructors from thirty to fifty-eight; a new building was occupied; the laboratory method of teaching was extended and improved; the activity of the school as a center of medical investigation was heightened; the compulsory four years' course of study went into effect; the annual receipts and expenses of the school increased by about 75 per cent. A most satisfactory showing for the decade, and a conclusive proof that a high standard of medical education is not incompatible with increased classes and revenues, but the contrary.

**Medical College of Virginia.**—Since the return of the classes of 1894-95, in attendance at the Medical College of Virginia, was made (as published in the *JOURNAL* of January 12), the aggregate has been increased to 138. This increase is in accordance with the information conveyed in the following note from Dr. Christopher Tompkins, Dean of the Faculty, the reference number to which was transposed as previously stated: "We have ten State scholarships, given in consideration of the fact that we receive aid annually from the State. We have no other scholarship feature, as is so often found in other medical institutions, or our number of matriculates would have been greatly increased. We have no dental or pharmacal department connected with our school. It is proper to state that the number of students as above for season of 1894-95 is incomplete, as we expect a number more

to come in soon." The Medical College of Virginia is a three-year graded school of six-months' sessions, is one among the oldest in the country, this being its fifty-seventh session, and is a member of the Southern Medical College Association.

**Malarial Influence in Abortion and Sterility.**—At the Indian Medical Congress last December, Mr. A. J. Weatherly, M.R.C.S., Eng., L.R.C.P., Lond., gave his experience in Africa, Florida and India on malarial influence in abortion and sterility. In England and in healthy parts of South Africa where malaria is unknown, he had ninety-one confinements at term with four abortions. In malarious parts of Africa and India he had 100 confinements at term and 48 abortions, and in Florida 30 confinements at term and 22 abortions. He has observed that a large proportion of his cases, though living in malarial districts, did not abort at times of attack of fever—in fact, in very many cases malaria showed itself only in the habit of abortion. He has also noted that a very much larger proportion of women are sterile in malarial districts than in others and that if they reside many years in such districts this sterility becomes permanent; whereas, if they leave before too long a time has elapsed they may bear children. He adds: "The influence of malaria on abortion and temporary sterility is still more marked in the very deadly malarious climate of Florida, where I saw twenty-two cases of abortion to thirty confinements at term, and ten cases of temporary or permanent sterility in a period of two years in a very small district."

**Against the "Christian Scientists."**—Following is the full text of the measure now before the New Hampshire Legislature to govern and regulate fraudulent medical practice and the so-called Christian science or faith cures:

SECTION 1.—No person within the limits of this State shall treat, attempt to heal or cure any other person or persons by the so-called Christian science or faith cures.

SEC. 2.—If any person shall treat, attempt to heal or cure, or claim or pretend to heal or cure any other person or persons by either of said methods and shall directly or indirectly accept or receive any money or other thing in payment for or on account of such services, or directly or indirectly accept or receive any gift or reward therefor in any form, such person so offending against the provisions of this act by so accepting or receiving such money, gift, reward, or other thing shall be fined a sum not exceeding three hundred (\$300) dollars for each and every offence, and half of such amount to be given to the complainant, the other half to the State.

SEC. 3.—This act shall take effect upon its passage.

**Semi-Centennial of the American Medical Association.**—Extract from a forthcoming volume, entitled "Personal Reminiscences," by Samuel C. Busey, M.D., Washington City, D. C.—"I was present at the meeting of the AMERICAN MEDICAL ASSOCIATION held in Philadelphia, in May, 1847, and was present when Chapman was elected President, witnessed the dignified formalities of induction into office, and heard his inaugural address of thanks for the honor. The circumstance of my presence at the first session, and witnessing the inauguration of the first President of that august assemblage of medical men, suggested the inquiry to ascertain the number, names and residences of those who have survived the period of forty-seven years since elapsed. I am enabled, through the politeness of Dr. Wm. B. Atkinson, the Permanent Secretary, to state that but five are now (July, 1894) known to be living. They are Hiram Corson, Plymouth, Pa.; Alfred Stillé and Lewis Rodman, Philadelphia; Oliver Wendell Holmes,<sup>1</sup> Boston; and Nathan S. Davis, Chicago.

"There were undoubtedly many students like myself residing in Philadelphia, who attended the meeting, and it would

be interesting to ascertain their names and residences, but it is not possible to do so, except by their voluntary statement of the fact of their presence.

"In view of these facts it seems eminently proper that preparations should be initiated at Baltimore, in 1895, for an appropriate commemorative celebration of the semi-centennial anniversary at Philadelphia in 1897. Efforts should be made to secure the attendance of the survivors of the founders, and also of those now members who were students in attendance as spectators in 1847. This latter proposition is somewhat experimental, inasmuch as there is no record of such accidental attendants, whose casual presence would hardly entitle them to official participation in such commemorative ceremonies."

**Surgical Pathology of Madagascar.**—Dr. Thesen, in charge of a Norwegian hospital at Tananarivo, has issued a report of the work done by it, which is quite large considering that it has only thirty beds. From a summary in the *Bulletin Medical* it is learned that in three years 300 administrations of chloroform were given, with one death from pulmonary edema; 211 cataracts were operated on, three unsuccessfully. The so-called senile cataract appears early; three patients were only 31 or 32, and a large number had not passed 50. Autoplastic operations comprised twelve barelips, ten transplantations and two rhinoplastics. Various kinds of tumors were operated on, among them fifteen cases of elephantiasis Arabum, fourteen of which were in females from 18 to 40 years old, all in connection with syphilis which had not been treated. M. Thesen states that the doctor who makes his observations in Madagascar can not deny the intimate etiologic relation which exists between syphilis and elephantiasis of the genital organs. Malignant tumors were rare; in three years only three cases of sarcoma and six of carcinoma being noted. Osseous and articular tubercles seem excessively rare, for no case occurred. Abscess of the spleen and liver is common; stricture of the rectum either from syphilis or dysentery is also common. Hemorrhoids are very frequent—forty-five cases were operated on. In the three years forty-one operations for vesical calculi were performed, 59 per cent. uric acid, 18 per cent. mixed, 9 per cent. phosphatic, and 14 per cent. oxalate of lime; three quarters of these were children under 15. The author adds that the hygiene in the town is deplorable. It is necessary to go a long distance for drinking water. The morals are very lax. The climate is not suited for any one from the north of Europe; those from the south easily become acclimated.

**Can give Opinion as to Effect of Tumors.**—In an action brought to recover damages for personal injuries a question was put to a physician which called for an opinion "upon the exciting cause of the illness" from which the plaintiff suffered from Jan. 9, 1887, till her death, on May 18, 1892. The nature of the illness was described in the question. The answer was: "From the result of the autopsy, knowing that there was a tumor of the brain, I presume that was the exciting cause of the troubles from which she suffered." When the witness was called, the counsel for the defendant admitted him to be a good practicing physician, a graduate from a good institute, and of long experience, but not an expert on tumors. The exceptions also recited that: "Before the hypothetical question was put to him he was asked if he was familiar with tumors of the brain, to which he replied that he was not. He was then asked if he knew what caused tumors, to which he answered that he did not mean to be understood that he understood the causes of tumors; that he knew what the authorities said in regard to them; that the causes were chiefly unknown." The Supreme Judicial Court of Massachusetts holds, in the case of *Hardiman v.*

<sup>1</sup> Died Oct. 8, 1894.

Brown, decided Jan. 3, 1895, that the physician was qualified to answer as he did the hypothetical question put to him. It says a good practicing physician, of long experience, who knew what the authorities said in regard to tumors, could properly be permitted to answer the question as this one did, although in his practice he had not been familiar with tumors on the brain, and did not pretend to understand the cause of tumors. He was not permitted to give any opinion upon the cause of the existence of the tumors at the base of the brain of the plaintiff, but only of their effect in producing the symptoms of disease which appeared in the plaintiff's case. A doctor of medicine may be competent to express an opinion upon the effect of pressure at the base of the brain, whether it arises from tumors or other causes, although he may never have been called to a case where tumors were known to exist there; and, in determining the qualifications of a physician, the extent of his reading in his profession may be considered, as well as his experience.

**Depopulation of France.**—In a discussion before the Paris Academy of Medicine, reported in *Le Progres Medical*, M. Cadet de Gassicourt said that the doctors, while seeking to diminish mortality, could do very little to increase the birth rate. M. Javal thought that physicians, might by their counsels, have some effect against the diminished birth rate; the latter is caused principally by the voluntary sterility of families, and physicians could point out the hygienic evils entailed by it. M. Guerin had little faith in the efficacy of the physician's advice. He believed the depopulation arose, in the first place, from people leaving the country to go to the cities; hence the children, which in the country were riches, so to speak, in the city were a charge and a constant source of uneasiness. While physicians can be of but little help in overcoming this diminished natality, surgeons can do something by leaving a few ovaries from time to time. M. Charpentier showed the difficulties and the contrary results which statistics of infantile mortality often presented. He also believed the principal factor in the diminished birth rate arose from voluntary sterility—families in France did not wish for more than one or perhaps two children. M. Pinard, while admitting the influence of voluntary sterility, regarded M. Charpentier's assertion as slightly exaggerated. He had seen numerous families with more than two children. A singular fact showing clearly that sterility is voluntary is that when the sole child dies, the parents have another after ten, twelve or even fifteen years of sterility. M. Guerin cited the frequency of abortions; in a recent trial at Limoges, the prisoner had performed no less than 5,000 abortions. He also called attention to the influence of alcoholism on the parents, by diminishing fecundity and increasing infantile mortality. M. Lagneau said that in the country, in Normandy for example, the natality is most restricted. The social conditions and the more or less easy outlet offered to children of the numerous families played the preponderant rôle. M. Lannelongue had particularly studied the influence of alcohol; this is very difficult to interpret. In parts of the country which consume the most alcohol, as in Brittany, we find the fecundity is considerable. In the most isolated districts, in Gers for example, natality is very low, but he admits the influence of alcohol on infantile mortality. These are the principal arguments invoked to explain the diminished birth rate. It seems that the system of taxes which weighs so heavily and so directly on large families may also have something to do with it.

**The Pacific Coast Association of Life and Accident Insurance Examiners.**—Early in January a circular, signed by Dr. C. K. Cole, of Helena, Mont., Nominator, Equitable Life of New York; Dr. J. B. Eagleson, of Seattle, Wash., Referee, Mutual Benefit Life of Newark, and Dr. Henry W. Coe, of Portland, Ore., was sent to the Insurance Examiners of Montana, Idaho, Utah, Washington, Oregon, California and British Columbia, inviting them to meet in Parlor B, of the Portland Hotel, Portland, Ore., on Wednesday, January 30, at 10 A.M., for the purpose of forming an Association of Insurance Examiners. In reply to this call, sixty-six applications for membership were received and the Association was successfully organized under the above name, with representatives from seven States and Territories. The following prelude

to the By-Laws states that "the object of the Association is to live interest in the important department of life and accident insurance work of physicians. To widen the knowledge of its membership upon such subjects through interchange of ideas and unity of purpose, to the end that the local examiner and surgeon may have a broader view of his duties and responsibilities, do his work better, and thereby protect to a fuller degree the companies which have intrusted vast interests to his care. Also to devise any necessary protection of the examiner in the legitimate pursuit of such avocation against encroachments upon his, from any and all sources."

During the meeting the following papers were read and discussed: "Fees for Life Insurance Work," by Dr. H. W. Coe, of Portland; "References," by Dr. G. S. Armstrong, of Olympia; "Overweight," by Dr. H. W. Coe; and "Careless Examinations," by Dr. W. F. Amos, of Portland.

It was decided that the meetings hereafter should be held at the same time and place of one of the State medical societies of the region covered by the Association. The next regular meeting will be held at the time of the Washington State Medical Society at Seattle, on May 18, 1895.

Dr. Richmond Kelley, of Portland, Ore., was elected President, and the following Vice-Presidents elected to represent the States to which they belong: Dr. L. M. Sims, of Kalama, for Washington; Dr. W. J. McGuigan, of Vancouver, for British Columbia; Dr. F. D. Bullard, of Los Angeles, for California; Dr. C. K. Cole, of Helena, for Montana; Dr. C. L. Sweet, of Boise, for Idaho; Dr. C. S. Baldwin, of Salt Lake City, for Utah; and Dr. J. D. Fenton, of Portland, for Oregon. Dr. Henry W. Coe, of Portland, was elected Secretary and Treasurer.

This is the second Association of Insurance Examiners organized in this country (the first being the Georgia State Society of Insurance Examiners), and from its large membership and the enthusiasm of its organizers, it will no doubt be the means of doing much good among its Fellows and for life and accident insurance work generally.

### Washington Notes.

**MEDICAL SOCIETY OF THE DISTRICT.**—At the meeting of the Society held on the 6th inst. Prof. W. J. McGee read a paper entitled, "Primitive Trephining in Peru," and illustrated it by the Muniz collection of crania. Dr. G. N. Acker reported two cases of heart disease and presented the specimens. Dr. J. T. Johnson reported a case of extra-uterine pregnancy and presented the specimen. On the 13th inst. Dr. Sofie A. Nordhoff read a paper on "Kinetic Therapeutics in Gynecology or Thure Brandt's System." Dr. Stone reported a case and presented a specimen of cancer of the ovary.

**THE WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.**—The two hundred and twenty-third meeting of the Society was held on the 15th inst. Dr. Van Rensselaer read a paper on the "Necessity for Early Operation in Mammary Cancer." Dr. Bowen reported a case of stricture of the female urethra and exhibited the patient.

**THE FOLLOWING CIRCULAR** has been sent by the Health Officer to the physicians of the city:

"Your attention is respectfully invited to the following amendment to the Regulations made under the Act to prevent the spread of scarlet fever and diphtheria in the District of Columbia, approved Dec. 20, 1890.

"SECTION 3.—Is hereby amended, to take effect Feb. 15, 1895, so as to read as follows:

"SEC. 3.—The warning sign shall remain on premises in which there is a case of scarlet fever for a period of not less than three days after the complete recovery of the patient as certified by the attending physician.

"The warning sign shall remain on premises in which there is a case of diphtheria for a period of not less than four weeks from the complete disappearance of the membrane as certified by the attending physician, but may be removed before the expiration of that period if a bacteriologic examination by a competent person has demonstrated the absence of the Klebs-Löffler bacillus.

"In no case will the warning sign be removed before the premises have been disinfected to the satisfaction of the Health Officer."

**MORTALITY OF THE DISTRICT.**—Notwithstanding the severe winter weather for the last week, a condition of good health prevailed throughout the District. As shown by the returns of mortality to the Health Department, there was one less death than in the previous report. The death rate for the whole population fell to as low a figure as 15.66, as compared with 20.43 for the corresponding week of last year. There was a slight increase in the number of fatal cases of chronic affections, accompanied by a relative decrease in acute lung attacks. There seem to be no malignant fevers prevalent, and mortality among the aged over 60 years and children under 5 years is at a minimum and below the average. The effort to limit and eradicate smallpox is apparently proving successful.

**EASTERN DISPENSARY.**—The Commissioners have transmitted to Chairman Williams of the Sub-Committee on District Appropriations of the House, the needs of the Eastern Dispensary, an institution which has been in useful existence for several years. It is managed by some of the best citizens, ladies and gentlemen of high standing, who have carried it on without much aid from the public funds. For a year or two the Commissioners have devoted \$500 per annum of the appropriation for the relief of the poor for that institution. It has recently come to the attention of the Commissioners that the lady managers are desirous of establishing an emergency hospital service for the eastern part of the city of Washington, and with this end in view they ask for an appropriation of \$1,000 for the fiscal year 1896.

**ST. ELIZABETH'S HOSPITAL.**—W. W. Godding, Superintendent of the Government Hospital for the Insane, has submitted a report to the Commissioners for the month of January, 1895, noting the changes among the inmates of the hospital, and admissions during the month by order of the Commissioners. During the month there were admitted nineteen white and five colored inmates. During the month there were fifteen dismissals, of which number nine died, four being colored and five white, and the remainder on visit and improved.

#### Louisville Notes.

**MORTALITY REPORT.**—The report of the Health Officer shows a total number of deaths of seventy-seven, and of these more than one-third, twenty-seven, were due to pneumonia. This is an unusual death rate from this cause, and shows the generally severe type of the disease which prevails this year. Of the number, forty-three were male and thirty-four female, sixty-four white and thirty-four colored, fourteen were under 1 year of age, and twenty-six from 50 to 80 years of age. There were five deaths from cerebral meningitis, six from consumption, three from typhoid fever.

**SMALLPOX.**—The smallpox which was reported in these columns recently as having developed in Lexington, Ky., shows no signs of being under control. Four new cases have been reported, and at a special meeting of the council on the 13th, it was decided to establish a pesthouse. Every precaution is being taken to prevent its spread to this city. All of the stable boys and jockeys now at the Churchill Downs race track have been ordered vaccinated by the City Health Officer, and all newcomers must be vaccinated by one of the city physicians.

**ILLEGAL PRACTICE.**—During the week the attorney for Dr. Rice who is charged with illegal practice of medicine, moved in the police court to quash the two warrants that have been pending for some time against Dr. Rice. The counsel of the State Board of Health objected, and the warrants were filed away, as Dr. Rice moved from the State before they could be served on him.

**RAILROAD AGREEMENT.**—For a number of years the hundreds of medical students in this city at the close of the college term, have been in the habit of clubbing together and demanding rates and other concessions which the agents have oftentimes granted to get travel. If one road did not grant

the concession it had the alternative of seeing another road gain the business. The medical student travel in and out of the city is very large owing to the number of colleges here, and to secure their business is a great stroke on the part of any passenger agent. The agreement made between the outgoing roads from Louisville was to hereafter make no concessions to medical students in order to gain their business, but to sell tickets to them at tariff rates as they are sold to other travelers. The agreement was entered into as a means of protection, as the roads saw that a continuation of such conditions would bring upon them much loss and a perpetual state of unrest. No affront is meant to the medical students, but they state they have simply taken a step which is just to themselves and the public generally. The roads also stipulate that they will allow the medical students no meals or other concessions as bait for the business.

#### Hospital Notes.

**PLANS** have been drawn for the new hospital for contagious diseases at Rochester, N. Y. The building will be one story in height, thirty-three feet wide and one hundred and fifteen feet long.—The forty-eighth meeting of the Alumni of charity hospitals was held in New York February 8. Dr. Adolph Rupp presided.—An annex to the Kansas City Hospital took fire February 8. The blaze was extinguished before serious loss resulted.

### THE PUBLIC SERVICES.

**Army Changes.** Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Feb. 9, 1895, to Feb. 15, 1895.

Col. CHARLES C. BYRNE, Asst. Surgeon-General, is relieved from duty as Medical Director, Hdqrs. Dept. of Dakota, and announced as Medical Director, Hdqrs. Dept. of the East.

Lieut.-Col. HENRY R. TILTON, Deputy Surgeon-General, is announced as Medical Director, Hdqrs. Dept. of Dakota.

First Lieut. GUY C. M. GODFREY, Asst. Surgeon, will proceed without delay from Ft. D. A. Russell, Wyo., to Ft. Omaha, Neb., and report for temporary duty.

**Marine-Hospital Changes.** Official list of changes of stations and duties of medical officers of the U. S. Marine-Hospital Service, for the fifteen days ended Feb. 15, 1895.

Surgeon GEORGE PURVIANCE, detailed as chairman of board for examination of Asst. Surgeons for promotion, to convene in Washington, D. C., March 11, 1895, Feb. 8, 1895.

Surgeon J. B. HAMILTON, granted leave of absence for six days, Feb. 7, 1895.

Surgeon H. W. AUSTIN, detailed as member of board for examination of Asst. Surgeons for promotion, Feb. 8, 1895.

Surgeon FAIRFAX IRWIN, detailed as recorder of board for examination of Asst. Surgeons for promotion, Feb. 8, 1895.

P. A. Surgeon W. G. STIMPSON, to assume temporary command of Service at Port Townsend, Washington, during absence of P. A. Surgeon J. O. COBB, Feb. 13, 1895.

Asst. Surgeon J. M. EAOER, ordered to examination for promotion, Feb. 9, 1895.

Asst. Surgeon RUPERT BLUE, granted leave of absence for six days, Feb. 13, 1895.

Asst. Surgeon SEATON NORMAN, ordered to examination for promotion, Feb. 9, 1895.

#### LETTERS RECEIVED.

Busey, S. C., Washington, D. C.; Beck, Carl, New York, N. Y.; Beuchel, O. B., Battle Creek, Mich.; Bumgarner, A. E., Piquette, Ohio. Conant, W. C., New York, N. Y.; Crosby, W. E., New York, N. Y.; Conorton, M., Chicago, Ill.; Caldwell, F. H., Sanford, Fla.; Cantwell, G. M., Little Rock, Ark.

## ORIGINAL ARTICLES.

### THE TECHNIQUE OF OPERATIONS FOR CANCER OF THE BREAST.

Read before the Denver and Arapahoe County Medical Society,  
Jan. 29, 1895.

BY CHARLES A. POWERS, M.D.

CONSULTING SURGEON TO ST. LUKE'S HOSPITAL AND ATTENDING SURGEON  
TO ST. ANTHONY'S HOSPITAL; LATE ATTENDING SURGEON TO ST.  
LUKE'S HOSPITAL AND TO THE CANCER HOSPITAL, NEW YORK.  
DENVER, COLO.

I do not feel that apology need be made for introducing to the society for discussion, the subject embodied in the foregoing title; the widespread and increasing prevalence of cancer of the breast,<sup>1</sup> its painful and terrifying features, and, above all, the very great attendant mortality, render it one of the most important of surgical conditions and one in which the most strenuous effort should be made to cure, and when cure be impossible, to ameliorate. The views which I have the honor of laying before you are based on some fifty operations in my own hospital and private practice. These operations have been done under modern methods and nearly all the cases have been followed from year to year. You will, therefore, pardon me if my observations are largely personal, and if I quote but little from other writers.

With the causes of cancer in general, we are as yet unfamiliar. Heredity bears but a slight relation, predisposition and trauma are still indefinite. The parasitic theory has of late years had zealous advocates and equally positive negations. At best it remains unproved. Discussion of this, however, is without the scope of this paper. So, as well, of the diagnosis but little need be said. A persistent lump, be it large or small, in the breast of any woman, young or old, is a matter demanding the most careful consideration. It may be cystic or solid. This will be determined by the exploring syringe. If it be solid, its malignancy can often be accurately determined only by incision. In those at or beyond middle life, a solid tumor is generally cancer. In girls, while the chances are quite in favor of adenoma or fibroma, a sarcoma may be found. In patients between the ages of 20 and 35, any of these forms may be encountered. I have more than once seen cancer of the breast in a woman under 30 years.<sup>2</sup>

So, in general, whatever be the age, the earlier our diagnosis be made accurate, the better it will be for the patient.

Operations for cancer of the breast are designed to be curative or are merely palliative, and it is needless to say that the end in view is determined by the extent of the neoplasm. Whatever this may be, the

preparation of the patient is practically the same. The bowels are well moved on the day preceding the operation, the chest, axilla and arm well scrubbed with soap and water and thoroughly shaved and a green soap poultice applied to the region of the incision and the surrounding parts. This is left on over night. On the morning of the operation the green soap is removed, the parts scrubbed with a 1 to 1,000 sublimate solution and a compress wet in this applied and left in place until the patient is under ether. If there be an ulcerated area it may be covered with iodoform gauze and collodion, or it may be touched with the thermo-cautery after the patient is anesthetized. The assistant who is to give the anesthetic should prepare his hands as though he were to participate actively in the operation itself, and should wear a sterilized gown. Care should be taken to see that the ether cone is cleanly.<sup>3</sup> The best table is one of medium height, with the chest and head piece moderately elevated.

Let us assume, if you please, that the left breast is the seat of operation and that the tumor is of moderate size, not adherent to the chest wall and not in the periphery of the gland. The arm is abducted to beyond 90 degrees and held by an assistant or nurse. The skin incision must be ample, well distant from the supposed margin of the growth. It is of advantage in placing this incision to make light cuts in the skin for landmarks. One at the inner angle of the incision (which will be at about the middle of the inner, lower quadrant), one in the axilla at the lower border of the tendon of the pectoralis major, and one each at the middle of the breast above and below.

These landmarks are of distinct advantage, for when the tissues are placed on the stretch in cutting, it is difficult to estimate the amount of retraction which has been made.

This upper cut goes well through the skin and subcutaneous fat; at the outer upper margin of the growth it swings down below the pectoral tendon and is prolonged to beyond the middle of the axilla. An assistant pulls up the inner flap and it is well dissected from the chest toward the median line. The knife then cuts toward the ribs, well into or through the costal portion of the pectoralis major, and a part or the whole of this muscle is raised, with a few deep strokes, from the chest wall. The surgeon's left hand, grasping the breast and lifting it, makes this easy.

At times a few vessels may require forcé pressure, often a sterilized towel crowded into the wound and firmly pressed down by an assistant will check oozing. The lower incision is then made, the lower, outer flap dissected up and the breast and underlying muscular tissue cut from the chest, the pectoral tendon

<sup>1</sup> Bryant, New York Medical Record, Jan. 19, 1895.

<sup>2</sup> I would like, here, to record the opinion that cancer is much more frequent in the third decade than is generally supposed. I have seen cancer of the rectum, uterus, lip, breast and stomach in patients under 30.

<sup>3</sup> The physician's hands and the cone are so near the field of operation. In one of my suppurative cases I felt that I could trace infection to this assistant.

severed and the mass left hanging by the fatty tissue beneath and below the pectoralis major. These fatty tissues are then carefully divided from the chest wall from above downward and outward toward the axilla. The axillary vein is exposed by cutting through overlying fascia. This is best accomplished by slipping a blade of a medium, blunt, curved scissors beneath the fascia and cutting from within outward. The vein should be exposed for some two inches or more, the fascia and fat carefully dissected from it. The tributary veins should be clamped before cut, otherwise they retract and ooze in a troublesome way. If involved lymphatic glands be adherent to the vein it (the vein) may be resected. I have not seen more than temporary edema follow this.

The entire axillary space is to be thoroughly cleared of the structures crossing it, the subscapular veins should be spared, the subscapular artery will not generally require ligation. The apex of the axilla and the space of Mohrenheim are to be carefully investigated and the contained fat and fascia removed. Finally, the entire mass of fat and glands is cut away from the serratus and latissimus muscles.

All bleeding is to be carefully checked and the wound closed. If the tumor be small the edges of the chest flaps can generally be approximated. If, however, it is large there will be a gap of large or small dimensions left. Here, in certain instances, the sliding flap method of Shradz will avail. In other cases lead plates with relaxation sutures will bring the flaps together as nearly as possible, and blood-clot (Schede) closure be obtained under strips of rubber tissue. Secondary skin grafting (Thiersch) may be done in eight or ten days.<sup>4</sup>

For sutures I prefer the silkworm gut, interrupted and not too closely placed. An axillary drain may be inserted or omitted. My recent cases have healed promptly without drain and under a single dressing. The ideal dressing is plain sterilized gauze. A mass of this crowds the fornix of the axilla well up, and the entire dressing is firmly and evenly held in place by broad strips of rubber plaster. A mass of sterilized absorbent cotton envelops the chest, with an ordinary binder over all. The arm is outside this and loosely fixed at the side.

The foregoing description applies to an ordinary case, in which the tumor is not large, say the size of a pigeon's egg, centrally placed and not adherent. It is needless to say that varying conditions demand essential modification in technique. If the cancerous mass be no larger than a plum and not extending to the under surface of the gland it suffices, I think, to remove the pectoralis fascia and leave the muscle. If the tumor be peripheral a corresponding amount of tissue must be removed in its vicinity. When the tumor extends to the base of the mamma, the greater pectoral must be excised, and it is worthy of note that two experienced observers, Halsted<sup>5</sup> and W. Meyer,<sup>6</sup> have recently advised that it be removed in all instances. Each of these surgeons has carefully devised a definite operation for the removal of both of the pectoral muscles, the former surgeon removing them in part, the latter *in toto*. Halsted reports fifty cases in which he has done this, which he calls the "complete" operation; and with the magnificent resources of the Johns Hopkins Hospital at his command we might well expect definite and ex-

tensive histologic reports of the involvement or freedom from invasion of the muscles, lymphatics, fascia, fat and other tissues. Such details are, however, lacking in the reports of his cases, and we must at present consider the proposition of theoretic value, though most certainly having the advantage of thoroughness and the wide removal of surrounding tissues. It is of interest to note that Halsted does not find this addition to increase the risk of the operation, and his patients regained excellent use of the arm in retaining the clavicular portion of the greater pectoral. I have repeatedly removed a large part of the muscle and have never seen resulting disability. As to the most important point in this proposition of Halsted and Meyer, the ultimate cure of the patient, we must await further report. For of Halsted's cases 75 per cent. have been done within the past three years (the generally accepted limit of "cure") and the remainder have but an average (22 per cent.) of freedom from relapse. Meyers' procedure is more radical, but he has had opportunity to apply it in but one or two recent cases. We shall await with much interest further reports on the all important question of radical cure.

The axilla must, in all cases, be invaded and thoroughly cleared out. This is a position universally accepted, which admits of no debate. It makes no difference whether glands be felt therein before operation. I have repeatedly found small, cancerous lymphatics in an axilla which seemed normal on palpation. The axillary dissection must be thorough and carried to the highest possible point. So, as well, it is of the greatest importance that the tissues between the breast and axilla, the fascia, fat and contained lymphatics be removed in a single mass.<sup>7</sup> It is useless to say that the cases in which the axilla is not involved are those in which the prognosis is the best. Invasion of the high axillary glands makes it almost certain that there are involved lymphatics beyond reach. And I have been led, also, to expect speedy recurrence in those cases in which the axillary fat has a sandy, granular feel. Halsted advises in every case the excision of the supra-clavicular glands. This adds but a few moments to the length of the operation and one can but regard it as of material value.

Throughout the entire procedure, active assistance is of the greatest importance. All bleeding vessels should be promptly seized, the retraction should be intelligently made, especially when the axilla is the field of work. It is of distinct advantage to make the proper flaps at the first cuts, for if they require revision time will be lost in checking the accompanying hemorrhage. A "dry" wound is the best assurance of prompt healing.

In those unfortunate cases in which the disease is too far advanced to permit thought of mere palliation, operation is justifiable whenever it is felt that life may be prolonged and the comfort of the patient enhanced thereby. In such instances the operation may be modified to suit the requirements of the individual case. Our rule in regard to these palliative procedures should be a simple one; to act as the best interests of the patient demand.

As has been said, these cases may be put up with or without drainage. In my latest cases, in which I have operated in the dry, aseptic way, I have been able to dispense with drains. Unless there be some indication for change the first dressing may be left

<sup>4</sup> In general I have found this preferable to primary grafting.

<sup>5</sup> Annals Surgery, November, 1894.

<sup>6</sup> N. Y. Med. Record, Dec. 15, 1894.

<sup>7</sup> All incisions outside the cancerous tissue.

until the sixth or eighth day, at which time the silk-worm stitches are removed. From this time on, the patient is encouraged in the use of the forearm and arm. The functions return in due time and I have never seen permanent disability in patients in whom the axillary fornix had been crowded well up.

The immediate prognosis in the modern operation for cancer of the breast is good. I have myself had some fifty operations without a post-operative death. Halsted reports seventy-six cases without mortality, Weir over one hundred. In general, the death rate is 2 or 3 per cent. As regards the most important feature, the ultimate result, statistics are steadily improving. The most important contribution to this, in fact the most valuable article on cancer of the breast, which has yet appeared, is the recent paper by Bull.<sup>8</sup> This surgeon reports 118 personal cases, of which he traced to the end 115, or all but three. The exceptional value of these data will be appreciated when we realize that all of these cases were carefully and conscientiously followed from month to month. A large proportion of them were seen by me and examined every three or six months.

In case of death, the statements of the attending physician were obtained as to the cause. Patients who lived at a distance were regularly examined by the family physician, and his report noted from time to time in the history.

Bull's cases are properly divided into two classes: 1, those operated upon during the past three years; and 2, those previous to that time. Of these the second class alone are utilized as to ultimate results, seventy-five in number. And of these seventy-five cases, twenty or 26.6 per cent. are living, free from recurrence, at periods varying from three years nine months to ten years after operation. That is, 26.6 per cent. of all cases may be classed as "cured." This is, as Bull says: "A higher proportion of cures than has been previously reported."

Bull's statistics might, however, mislead us in concluding that the prognosis is less favorable than it really is, for his cases include those in which the operation was palliative, as well as those in which the disease was yet in an early stage. So, in this way, Bull finds on dividing his cases, that those in which the axillary glands were free from invasion show over 50 per cent. of three year cures.

I, myself, in my last year's work at the New York Cancer Hospital, divided my operable cases into three classes, as follows:<sup>9</sup>

1. Those in which the disease is so limited that it is thought reasonably probable that it is entirely excised and that the patient has a fair prospect of cure.

2. Those cases in which the surgeon is doubtful, after removal, whether he has gone beyond the limits of invaded tissue; and,

3. Cases frankly incurable, in which a palliative operation affords a fair prospect of adding to the life and comfort of the patient.

It is needless to say that no sharp dividing lines can be drawn. One places an individual case in its approximate class after he has operated, and after he has read the detailed report of the pathologist.

It would be quite as irrational to include all cases of pulmonary tuberculosis in one class, both incipient and advanced, and to say that the percentage of

cures is thus and so, as to pursue a like course in cancer. An adherent breast cancer the size of a cocoanut is one thing, a nodule no larger than a robin's egg is quite another matter; and it is obviously unfair to allow the latter to bear the recurrence percentage of the former.

The histologic examination of the parts removed is of the greatest importance and should be made in a most thorough manner. No specimen can be certified as cancer until the microscope has so proved it, and it is not sufficient to make a perfunctory examination of a piece of the tumor itself. Segregated glands should be carefully examined, especially those lying highest in the axilla. It has been my custom to mark certain outlying portions of the breast, skin, muscle, fasciæ, glands, etc., for special report by the pathologist, and he should note the amount of healthy tissue intervening between the tumor itself and the cut surface of the parts removed. In this way alone, may we be reasonably assured that we have gone beyond the confines of the growth, and in this way, as well, may we compare with the original history of the case the development of recurrent nodules.

Our responsibility in these cases of mammary cancer does not end with the simple removal of the growth. The patients are to be placed under the best hygienic conditions and are to be followed carefully from year to year. My own rule has been to instruct them to return for thorough examination every three months, and in the interim, if they find evidence of suspicious nodules. The more intelligent class of people will, as a rule, see the necessity for this and gladly comply. The poorer classes will often fail to return and must be looked up in their homes. As an evidence of the thoroughness with which this can be done, I may again refer you to Bull's list of 118 cases in which 115 were kept under constant observation to the end. Internal recurrence admits of no relief. Local nodules may, however, be removed from time to time, and while in general the prognosis in recurrent cases is unfavorable, yet we may often add to the comfort of the patient and at times achieve a lasting cure.

As an example of the value of this frequent revision I may cite the case of a woman of 46 years who was in one of my wards at the Cancer Hospital in May last. Bull had removed the right breast of the patient for cancer some four years previously. A year later Weir excised an extensive scar recurrence. Something like a year after this, I removed the opposite breast and axillary contents for a cancerous nodule, the size of a robin's egg, and have since excised small nodules on four different occasions from the scar of the right side. Her general health has not yet suffered and she is able to support herself and children. It is now over four years since her original operation, and but for the fact that she has been watched constantly, she would doubtless have died long since.

I purposely omit more than the briefest mention of the use of erysipelas injections in malignant growths. In sarcoma the method seems deserving of the most extended trial. In carcinoma we have practically no evidence that it is of value.

I can but class these operations for cancer of the breast as among the most important with which we have to do in surgery; not that they are in themselves dangerous, but that the best chance for cure requires the exercise of mature judgment. And in

<sup>8</sup> N. Y. Med. Record, Aug. 25, 1894.

<sup>9</sup> N. Y. Medical Jour., September, 1894. I use the word "doubtful" in its broadest sense. It is needless to say that one never feels certain.

conclusion, I beg to express the view that mammary cancer is a curable disease, and that the keynote to its successful management is to be found in the earliest possible diagnosis, prompt and wide excision and careful observation of the patient during the remainder of her life.

Stedman Block.

## RELATIONS OF DISEASE, CRIME AND VICE..

Read before the Omaha Medical Society, Dec. 11, 1894.

BY W. O. HENRY, M.D.

PROFESSOR ORTHOPEDIC SURGERY AND GYNECOLOGY IN THE JOHN A. CREIGHTON MEDICAL COLLEGE, OMAHA, NEB.

I would define these terms by saying that disease is the violation of any physiologic law or any abnormal activity in living tissue. Crime is the violation of any human law, or any abnormal activity in the civil world. Vice is the violation of any moral law, or any abnormal activity in the moral world.

We have to-day in the United States more than one hundred thousand tramps who find it easier to get a living by begging from door to door than by labor, and hence take to this sort of life.

There are more than five hundred thousand criminals in this land to-day and only one-fifth of them are behind the bars. It is estimated that two women out of every one hundred in this country are fallen women. The percentage of divorces to marriages is alarmingly great so that in some States there is one divorce granted to every twelve marriage licenses issued. Ten thousand children roam the streets of Chicago homeless and without suitable food, clothing, shelter or guardianship. While this appears to be a very large number it is probably not greater than will obtain elsewhere.

Although it is impossible to get at statistics upon the frequency of criminal abortions, yet so prevalent is it even in the so-called "better" classes of society that in some quarters a great cry has justly been raised against it in which every physician should join, for he alone has any adequate conception of its frequency and disastrous results, morally and physically.

By sentimentalists and would-be reformers it has of late become quite common, and especially since the "Keeley cure" and "Christian science" fakes, to hear it affirmed that alcoholism or drunkenness is a disease and the victims are irresponsible for their acts. Thus morphinism, cocainism and allied disorders are placed in the same category, and heredity is very properly given a prominent part in their production.

T. D. Crothers, of Hartford, a recognized authority, estimates that there are in the United States 1,600,000 excessive drinkers besides a large number of victims to morphin, chloral, cocain and other narcotic drugs. He says: "Alcohol used either in moderation or excess, always deranges sensation and the brain centers, which receive and determine the value of the impressions. False impressions come from the senses and the brain is unable to correct them. Associated with this the delusion of mental health, and clear accurate judgment of his conditions and surroundings. This condition is present in every drinking man, only different in degree. . . . The criminal acts of the inebriate spring from this confusion

of sense and judgment. This shows the irresponsibility of inebriates."

Dr. L. D. Mason, of Brooklyn says: "The large majority of inebriates become so from necessity, not from choice, there being a *vis a tergo* of heredity, environment and disease that produces physical degeneracy and plunges them into drunkenness."

Wilson, of Edinburgh, says: "Drunkenness is the outcome of an ill-organized constitution."

Two noted French medical authorities in a report to the Government Hygienic Committee give the opinion that, "alcoholism is now a social danger, undermining the bodily and mental health of posterity, and that from its injurious influence on the children and ulterior descendants of the habitual consumer, a degeneration of the whole nation is being induced."

The large increase of drinkers among women both in this country and England is a cause for serious alarm. Lawson Tait says: "An educated and intelligent woman never becomes a drunkard but from some deep-rooted and often carefully concealed cause. The indulgence may be from physical suffering or mental distress." He holds that many of his cases of suffering from inflammatory affections of the uterine appendages have been cured of these habits by the treatment which cured their physical suffering.

Dr. F. O. Marsh, of Cincinnati, in a paper read before the Miami Valley Medical Society upon morphinism said: "The deviation from the normal standard of nerve nutrition and nerve function resulting therefrom, and which impels to and necessitates the continuance of morphin is a disease. . . .

The moral responsibility of the patient at any given time for the continuance of the habit diminishes in direct proportion as the nerve degeneration has become deep-seated and inveterate."

Dr. Norman Kerr, of London, says: "The permanent impairments of the nervous system in inebriety are described as phases of alcoholic dissolution, a retrogressive pathologic process. In the etiology of alcoholic nerve degeneration there are two elements, viz., the effects of the direct pathologic action of alcohol on the newer tissues, and of the impoverished blood supply. These are chiefly the breaking down of the nerve elements, with thickness and inelasticity of the blood vessels and overgrowth of the connective tissue. The gradual appearance and development of an appetite for excessive drink often indicates brain degeneration."

Dr. B. Clark, of New York, in speaking of alcoholism says: "It is responsible for over one-half of the sum total of human miseries." Again he says: "It is a disease that can be managed much more readily than imagined and yet a disease which few physicians know how to handle when called upon to do so."

Henry O'Neill, of Belfast, cites among police cases, the fining of a woman 10s. for drunkenness who had been convicted of the same offense ninety-two times. Another woman fined 10s. whose previous record was 140 convictions, and still another fined 20s. who had been before the court on a like charge 170 times. He then states that nearly all the highest penal records had been of women and draws the conclusion that fines and punishment are failures as reformatory measures. Therefore it is said: "It is inevitable that drunkenness is a disease, not a crime. In German, Austrian, Swiss, Italian and Dutch law, there is a

distinction between culpable and inculpable intoxication. English laws generally exact complete responsibility. In Austria a peasant farmer while intoxicated, killed his brother. In Britain he would have been hung, or, at least have received a very long term of imprisonment. Under the Austrian code provision of a reduction of punishment in the non-intent of intoxication, he served nine months imprisonment, became a changed man, and headed a temperance reformation in his district, where a monument has been erected to commemorate his great service to his country." Precisely the same kind of sentimental foolishness advocated by some Americans. So much, Mr. President, for drunkenness and its allied affections.

Dr. Hunter McGuire, of Virginia, in writing to Dr. Lydston, of Chicago, requesting a "scientific explanation of the sexual perversion of the negro of the present day," says: "Before the late war between the States, a rape by a negro of a white woman was almost unknown; now the newspapers tell us how common it is. In the South the negro is deteriorating, morally and physically. . . . During the days of slavery, insanity was very uncommon among the negro race. Now, our large asylums are not capacious enough to hold the insane negroes of both sexes." He then refers to their lack of proper food, shelter and clothing as compared with their former supply and says further: "We have also intemperance excess and impure air from overcrowding. . . .

Mental depression and anxiety are also common. Laughter and music, universal with them before the war, are now rarely heard. . . . Pulmonary phthisis and other purely tubercular diseases, while common enough in the mulatto, were comparatively infrequent in the negro. Now, however, . . . tuberculosis is fearfully common."

In his reply, Dr. Lydston very properly remarks: "Notwithstanding the horrible crimes perpetrated under the influence of the *furor sexualis* by the negro, particularly in the South, I believe that he compares quite favorably as regards sexual impulses—taking all abnormalities into consideration—with the white race. The more I see of white men in so-called refined society, the more contempt I have for quite a large proportion of male humanity."

Now, as to some of the reasons he offers as explanatory to the questions propounded let me cite a few:

1. "Hereditary influences descending from the uncivilized ancestors of our negroes."
2. "The removal of certain inhibitions placed upon the negro by the conditions which slavery imposed upon him."
3. "An incapacity of appreciation of the dire results to himself of sexual crimes."

Again he says: "The enormous increase of the negro since the war has had much to do with his physical and intellectual degeneracy, and therefore with his criminal propensities. As man descends in the scale of differentiation the number of offspring at a birth approximates the multiple pregnancies of the lower strata of animal life. Morel, De Monteyel, Hagen and one of our most eminent American writers—Kiernan—have conclusively shown that multiple pregnancies are most frequent among the degenerate types of humanity. The offspring in such multiple pregnancies are defective from an obvious double cause. Upon them, all degrading influences act with greater power." Once more he says: "The lack of

systematic occupation and the forced assumption of responsibilities for which he was by nature and training unfit—to say nothing of the acquirement of vices and profligate indulgences for which he had relatively few opportunities while he was in bondage, and for which he was directly responsible to those whose interest it was to keep him in the best possible condition morally and physically." Finally he speaks some ringing words which I wish might be burned indelibly into the minds of all men but especially medical gentlemen: "Ignorance of sexual physiology has led the average white boy, at the age of puberty, to believe that fornication is a necessity, or at least a luxury at which the whole world winks. You well know the train of misery following the indoctrination of such ideas. This fallacious idea is responsible for much of prostitution and sexual crime. . . . Sentimentality and morals aside, the most materialistic of us must acknowledge that sexual purity is wholesome in its effects. The remedy for the evils of youth and early manhood is, never to begin indulgences that create physical and injurious necessities."

The Chicago *Inter-Ocean* said: "Out of thirty-two young men in New York City who were recently examined for West Point cadetship, only nine were accepted as physically sound. Such a note might well make the young men of our cities pause for a moment's thought. Beer, the cigarette, too much amusement, and the hidden vices are making havoc with the physical manhood of all our towns and cities." Dio Lewis said: "This species of indulgence is well nigh universal, and as it is the source of all other forms—the fountain from which the external vices spring, I am surprised to find how little has been said about it."

Dr. J. D. Bond, of Cincinnati, well says: "If the progenitors of our boys practice unrestrained licentiousness in wedlock, the transmission of lust is as sure as though the prostitution were not sanctioned by law. . . . Any doctor who recommends prostitution to cure masturbation is ready to damn two souls to save one body and deserves to be hooted in his community."

Dr. Percy, in the President's address before the Military Tract Medical Association, said that the most prolific source of prostitution is, "Ignorance of things sexual on the part of all mankind," and held the medical profession correctly responsible in large part for this marvelous ignorance. In the same address he said: "The vast majority of legalized marriages the world over, but especially in America, are nothing more or less than legalized prostitution. . . . Is it any wonder then that the offspring of such unions become weak passionate creatures, a prey to all sorts of nervous ailments, and that sexually they show no stability of character? Is it strange that the product of such wedlock often becomes prostitutes and the employers of them?"

A physician speaking of the vices of young men says: "Let us also warn the unhappy victims of follies that are past undoing to improve the means of restoration while there is still hope. In its track we find the ravages of loathsome disease, physical, mental and moral degradation, disrupted homes, asylums filled with imbeciles and graves that have kindly thrown the mantle of oblivion over wasted lives." So much for licentiousness. Let us now refer briefly to heredity and crime in general:

In a little work entitled, "The Jukes," R. L. Dugdale reports that in seven generations a single abandoned home bequeathed to the world 1,200 descendants, a large majority of whom were idiots, imbeciles, drunkards, lunatics, paupers, prostitutes and criminals. Seven hundred and nine of the 1,200 have been registered and their history studied in Mr. Dugdale's work. He finds that while harlotry in the community at large averages nearly two out of every hundred women, it was over twenty-nine times more frequent among the Juke women. In the line of Ada Juke, better known as Margaret, the mother of criminals, it was found that crime among the men was thirty times greater than that in the community in general. Of the 535 children born, nearly 24 per cent. were illegitimate. Among the women of the Juke family, the number of paupers was seven and one-half times, and among the men nine times greater than in the community at large. Among the sick and disabled of both sexes, nearly 57 per cent. were paupers. . . . Summing up the crimes and pauperism of this single family, Mr. Dugdale estimates that in seventy-five years it cost the public over \$1,250,000, without reckoning the cash paid for whisky, or taking into account the establishment of pauperism and crime of the survivors in succeeding generations, and the incurable disease, idiocy and insanity arising out of this debauchery and reaching farther than we can calculate."

Dr. Van Fleet, in a paper read before the New York Academy of Medicine said: "In carefully looking over the ground, we find that we can divide the causes of crime into two groups, namely, the moral and the physical. They are so dependent upon each other and both so important that we find our thoughts constantly drifting backward and forward between the two." He says again in speaking of defective vision in certain criminal classes: "To them things are never as they seem; they think the whole world is wrong. They become criminals from necessity."

Dr. Bayard Holmes, of Chicago, in a paper read before the American Academy of Medicine said: "Only a very small number of physical defects, such as blindness and deafness, can be referred to heredity, but this is not the case with mental defects, or with those forms of mental incapacity which result in delinquency or criminality. Thus we find that the insane are, in a very large per cent. found in families in which the taint is hereditary." Again he says: "It seems to me that the medical profession ought to bring an indictment against that method of doing business which keeps one-fourth of our men idle all the time, all of our men idle one-sixth of the time, all men at work long hours when at work at all, and still puts into factories and shops children and women. It is the settled policy of capital to have at hand a large body of idle starving workmen. . . . From this condition of warfare in business, from the idle workers necessary to wage-slavery results our great burden of voluntary and involuntary able-bodied dependents. Of the criminal class 45 per cent. are essential criminals or criminals from defect. The criminals have increased in the United States from 1850 to 1890 over 400 per cent., while the population has increased only 180 per cent. . . . There is every reason to believe . . . that the great increment in crime during the past forty years has come through unjust and unethical laws and their inhuman administration, and through the production of a

large class of landless, homeless, and generally idle people through the natural evolution of society."

The late Dr. O. W. Holmes seemed to recognize the influence of heredity, especially in the moral world, for once upon being asked when the training of a child should begin, he replied: "A hundred years before he is born."

Superintendent Byrnes, of the New York Police Department, says: "I know that children of criminals are very apt to become criminals themselves."

It is hardly necessary for me to call your attention in detail to the evils following cancer, tuberculosis, syphilis and gonorrhea, for all physicians know only too well the dire results to homes, wives and children and therefore to the State of these diseases.

Now while I am ready to admit, as every intelligent medical man must admit, that disease and numerous hereditary defects may and do follow the drink, morphin, chloral, cocain and other evil habits, yet it is not true in general that these habits depend upon some internal *vis a tergo* over which the victims have no control, and that they necessarily become such victims and are therefore irresponsible for their conditions. This teaching I believe to be highly unscientific and immoral. The gentlemen who have drawn such conclusions have in my opinion been illogical in the extreme and their data do not warrant their opinions.

If, according to these gentlemen, every drinking man is diseased in a greater or less degree and therefore more or less unaccountable for his acts, and if the criminal is such from necessity, surely we are a people in a deplorable condition, for at least 90 per cent. of our adult male population drink in some degree, and they together with our entire criminal population can have little or no moral responsibility for what they do. But they are accountable; they can quit their drinking and control their appetites; they can refrain from crime and they do so under circumstances which prove the truth of the assertion. Why, in the matter of drink, it is well known that many, of their own free will, give up their cups never to return to them. Multitudes more by simply embracing Christianity stop *at once* their drink habits and criminal practices, but you never hear of the multitudes being immediately cured of smallpox, scarlet fever, tuberculosis or puerperal fever by such treatment.

The trouble is with these drinkers and criminals, in the main, that the rewards for reformation and the punishment for persistence in their evil courses is not sufficient to bring into play their will power. Now, accepting the facts furnished by the gentlemen from whom I have freely quoted, although in some instances drawing different inferences from those facts, allow me to present what I believe to be the legitimate conclusion of these facts, many of which may be confirmed by every physician in his own experience:

1. Inheritance, ignorance and idleness are fruitful sources of disease, crime and vice.
2. Poverty, overwork and slavery to corporations is a fruitful source of disease, crime and vice.
3. Every human being is entitled to a home, proper food, clothing, education and employment together with his earnings; failing to secure which he becomes a criminal and vicious in cases too numerous to mention; therefore it is the duty of the State to secure to her citizens these things.
4. Ovariectomy and testiotomy should be done for

sexual crimes, insanity and some other constitutional diseases and upon the incorrigibly vicious.

5. Physicians should teach the serious effects morally, mentally and physically of masturbation, licentiousness, prevention of conception, abortion, the drink and allied habits, both upon the victims and their posterity.

6. There is no question but parents transmit to their offspring tendencies to disease, crime and vice.

### REFRACTION IN SCHOOLS.

Read before the Minnesota Academy of Medicine, Feb. 6, 1895.

BY FRANK ALLPORT, M.D.

PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLGY IN  
MINNESOTA STATE UNIVERSITY, ETC.  
MINNEAPOLIS, MINN.

This is an age of prevention rather than of cure. The greatest efforts are being made to cure disease before disease occurs. Can anything more distinctly exemplify the disinterestedness of the physician than his earnest and unremitting efforts towards prophylactic medicine? Reflect for a moment upon the discovery of vaccination for smallpox, and the villification endured by its progenitors and advocates. Note the active work accomplished by the medical profession in all questions involving sanitary reform and hygiene. Observe the earnestness of scientists as they endeavor to prevent the existence of diphtheria, tuberculosis, cholera, etc., by laboriously exhausting their very lives over the microscope and test tube. No one can affirm but that the existence of disease is more profitable to the physician than its dissipation; and yet the proudest member of our profession is he who discovers a prophylactic rather than a curative measure.

Along this line of thought, one of the greatest reforms may be indicated in anything that establishes and preserves the health of the coming generation. The present generation is launched for good or for evil, and while relief to its necessities is most urgent, it surely can not compare with procedures calculated to produce in our descendants a race of people strong and vigorous in mind, body and heart. It is for this now well-recognized principle that wise and thoughtful philanthropists are engaging with accumulating energy, in the establishment of kindergartens, Sabbath and mission schools, gymnasiums, etc. They recognize the superlative importance of early training, and that the most efficient method of dealing with ignorance, vice and disease, is to emancipate the race from their existence.

The paramount importance of proper and well-regulated school-life becomes, therefore, clearly apparent, and educators should appreciate that in the sacred and responsible position occupied by them, it is their duty to carefully guard the body as well as the mind of the youthful generation intrusted to their charge.

Without doubt, many of the most distressing diseases incident to human existence can trace their origin to the school life of the sufferer. Admitting that such pathologic changes are not invariably the primary and direct offspring of improper school existence, but may be the result of the submission of an already vitiated and hereditarily changed constitution to improperly constructed and badly managed school buildings and school life, we can not, even then, as citizens, advisers and educators, shirk the responsibility. The tendency of modern civilization

leads toward education and progress, and such development should be encouraged. Such advantages are shared by rich and poor, by young and old, by the healthy and by the sickly, by those whose ancestors were blessed with vigorous minds and bodies, and by those who can only gaze retrospectively at a line of antecedents cursed by the presence of dissipation and disease.

Admitting the existence and operation of a law requiring a proper medical certificate before admission can be obtained to the school, there would still be a large percentage of scholars apparently healthy, but burdened by unfortunate inherited tendencies, capable of development under improper and vitiated circumstances. The responsibility of the present to the coming generation regarding school life is, therefore, enormous, and involves such questions as the location of school buildings, with regard to air, space and drainage; the construction of the building itself with regard to window space and the direction of light; proper ventilation, plumbing and drainage; the necessity for good and sufficient artificial illumination; the tendency towards overcrowding; the necessity for medical sanction before admittance to schools may be obtained; the use of proper drinking water; the providing of separate basins, towels and soap—which is an unquestioned source of contagion, especially of an ocular nature—the construction of desks of different sizes for different ages, so that the pupil may firmly plant his feet on the floor, and always occupy the same relative position to his desk; the construction of desks that are of the proper slant and height, and compel an upright position of the body in reading and writing, thus lessening the tendency to a contracted chest and distorted spine, which are prime factors in the production of consumption and spinal disease; the frequent intermission from studies and the change from one study and occupation to another, thus compelling a combined rest of eyes, mind and body; the proper regulation of the *means* of study, such as the distances and color of blackboards, the color of slates, the character of print and the paper upon which it is printed; the necessity for vaccination; the exclusion of contagious diseases, and the execution of advisable quarantine regulations and proper rules or laws, intended to exercise a beneficent care over the sight and eyes of the rising generation; these and many other subjects pertinent to the matter under discussion must appeal to the consciences of those having under their control the health and morals of these embryo men and women in whose hands must shortly be placed the future of our country. The scope of this article must necessarily preclude the possibility of even a casual discussion of most of these subjects, and the writer is, therefore compelled to limit his remarks to observations pertinent to the eye, and the pressure exerted upon it, by modern school existence.

The deleterious influence of education and intellectual advancement, upon the human organism can not be questioned. Not that knowledge invariably goes hand in hand with physical retrogression; but uneducated and untutored races are always superior types of bodily development, to those nations renowned for an insatiable appetite for knowledge.

The eye is no exception to the principle involved in this statement. The eyes of a people engaged in rural and pastoral occupations will demonstrate few,

if any, errors of refraction; and in races of a barbaric or semi-barbaric nature such pathologic conditions may be said to be positively unknown.

Ramas, who made an examination of 2,000 Mexican school children, found only 88 myopics, 60 hypermetropics and 10 astigmatics. He asserts that *pure* Mexicans rarely show *any* errors of refraction, and such deviations are almost invariably found in the mixed races. Compare this for a moment with the statistics of the German Empire, the home of the most highly intellectual people in the world. The most advanced seats of learning show that 50 per cent. of the pupils are afflicted with myopia, to say nothing of hypermetropia and astigmatism; and as if this were not enough, one school in Vienna produces 75 per cent. of myopic youths!

Unquestionably, therefore, school life is disastrously prolific of refractive errors, and should be controlled with every means possible by those having such matters in charge; and while it can not be denied that myopia is found much more frequently than hypermetropia and astigmatism, still the existence of the latter conditions must not be ignored, for they often enact an important function in the health and character formation of the scholar.

Still, from the very nature of myopia, and the possibility of its extreme development under adverse circumstances, combined with its influence on heredity, it becomes inevitably the most potential factor in the consideration of the matter under discussion.

Statistics on this subject are enormous, as from the time of Cohn's investigations in the Breslau schools in 1865-66 to the present time, more than two hundred thousand pupils have been examined by competent observers, for statistical purposes. These investigations have occurred in all civilized countries, under all circumstances of age, sex, race, cranial formation, health, heredity, intellectual advancement, and school architecture and management. Many of them have followed a certain number of pupils from class to class and from school to school. They all point to one inevitable conclusion, viz., that mental culture is obtained at the sacrifice of ocular perfection, and that such imperfections are usually myopic in their nature.

It is unnecessary to detail the reports of individual investigators, it being sufficient to remember that such men as Cohn, Jäger, Rüte, Erismann, Loring, Derby, Agnew, Risley, Hippel, Schmidt-Rimpler and many others of equal eminence, have contributed their time and ability to this work. Neither can additional investigation materially influence the consensus of opinion on the subject.

Certain facts have thus become established, and as they can not be further proved, our duty lies clearly in the line of an earnest and concerted effort tending toward, at least, a material mitigation of an existing evil. These facts may be briefly mentioned as follows:

The human eye at birth is normally decidedly hypermetropic. Herman, who examined the refraction of 110 children at about the age of 3 months, found them all hypermetropic without exception. Some deviations from these statements are recorded by observers who have detected myopia in very young infants by the ophthalmoscope; such instances are however, exceptional, and while doubtless true, immaterial.

The eye which shows hypermetropia in later life

probably never reaches the emmetropic line; but the eye which develops myopia, gradually assumes a condition of emmetropia, from which point its axis is elongated by circumstances of heredity, health and occupation.

The claim that myopia is entirely an acquired disease can hardly be substantiated, when we reflect upon the many instances, observed by all ophthalmologists, where myopia will run from father or mother to every child in the family; such cases can not be coincidences, neither can they result from certain peculiar environments. Dr. Matais, of Angers, France, examined the families of 330 young myopic subjects, and arrived at the following conclusions:

1. The hereditary influence of myopia is manifest.

2. It exists in 216 out of 330 families.

3. Hereditary myopia is characterized by its early appearance, its comparatively rapid development and the high average of its degree.

4. Myopia is transmitted from the father to the daughter 86 times out of 100, and by the mother to the son 79 times out of 100.

The same author believes myopia to be inherited in 65 per cent. of all cases, and claims that hereditary myopia is more sharply defined than the acquired form, and that it reaches a higher degree more rapidly, and complications are more frequent.

Dr. M. Kirchner, of Germany, who has made exhaustive researches on the subject, says that children are most liable to be near-sighted when both parents are myopic, less liable when the mother only is affected, and least so when the father is the source of transmission. Boys of myopic parentage are twice, and girls four times, as strongly inclined to myopia, as the offspring of non-myopic parents. He thinks that girls are a trifle more inclined to myopia than boys.

Schwabe believes that the highest degrees of myopia can invariably be traced to heredity.

M. Francesque Sarcy, the well-known French critic, whose intelligence and veracity can not be questioned, even though he is not a member of the medical profession, has some interesting personal experience which he reports in pleasing and picturesque language. He begins: "I was born near-sighted, dreadfully near-sighted; many physicians assert that persons are never born near-sighted, but only become so. Science may say what it pleases; I was born myopic. One day, prompted by a spirit of mischief, I got hold of the big silver spectacles which my father wore and clapped them on. Fifty years have passed since then, but the sensation I experienced is keen and thrilling to this day. I gave a cry of astonishment and joy. Up to that moment, I had seen the leafy dome above me only as a thick green cloth, through which no ray of sunlight ever fell; now, oh, wonder and delight! I saw that in this dome were many little brilliant chinks; that it was made of myriad separate and distinct leaves, through whose interstices the sunshine sifted, imparting to their greenery a thousand forms of light and shade. But what amazed me most, what enchanted me so that I can not speak of it to this day without emotion, was that I saw suddenly, between the leaves, and far, far away beyond them, little glimpses of the bright blue sky. I clapped my hands in ecstasy, and was mad with astonishment and delight."

Sarcy undoubtedly had congenital myopia, and in later life he became blind in both eyes. In one he

suffered a retinal detachment, and in the other a cataract. The latter eye was operated upon, and he acquired better sight in it than ever before.

The existence, therefore, of absolutely direct congenital myopia while rare, can hardly be doubted; and the frequent transmission of an inherited tendency in the tissues of the eye, only requiring favorable circumstances for development, is so evident that argument is scarcely necessary.

The question of the influence of race and nationality upon the development of myopia is one of some importance, and has engaged the attention of scientists for many years, but has not yet reached a satisfactory settlement.

There is greater proneness to myopia in some races than others, but such tendencies can usually be traced to greater intellectual advancement, which is indicative of greater eye strain. Cohn, for instance, when he examined the Constantinople schools found very little myopia, owing to the small amount of writing accomplished by the scholars, and the manner in which it was performed. The contrast between the eye of the Oriental youth and the German (where the percentage of myopia is easily 50 or 60 per cent. and in extreme instances, 75 per cent.) is, therefore, very marked; but the probability is that it is due *not* to nativity *per se*, or cranial formation, as claimed by Stilling (who argues that a low-broad orbit favors the development of myopia) but to indolence, inappreciation of intellectual advancement and mental and moral perversity on the one hand, and entirely opposite qualities on the other. The claim of Stilling can hardly be maintained in view of the fact that Pyska, of Dorpat, Russia, carefully examined 338 scholars, mostly of Esthic nationality, and found only 17 per cent. of myopes. Since these people have broad faces and low orbits, and the proportion of myopes is less than in the inhabitants of western Europe, Stilling's theory can not be correct. Pyska feels that the development of myopia depends on the demands made upon the eyes by modern civilization, and not upon the form of the cranium.

It has been claimed that the Jewish race is more prolific in myopia than others. There seems to be no valid ground for this assumption, other than can be found in the fact that Jewish vocations, the world over, are usually those of shop-keepers, money-changers, etc., which necessitates close application to books and textures. In countries where the great mass of inhabitants turn to open air employment, and where the Jew naturally gravitates towards commercial life, no surprise need be experienced if examination of scholars shows a wide discrepancy in the development of myopia; but proof fails to demonstrate the same variance where Jew and Christian are reared alike, and where inherited tendencies from one generation to another can be estimated upon a basis of similarity.

Dor claims that "the further south you go, the more normal eyes you find." This statement may not be exactly correct, and has been the subject of debate; still, when it is observed that in countries approaching the equator, where life becomes progressively indolent, application nears a minimum, the noon-day and other siestas are frequent and general keenness and intelligence are lacking, it becomes easy to believe that our Southern friends may more nearly approach a condition of emmetropia than those who reside further north.

Callan, of New York, examined 457 negro children, varying from 5 to 9 years of age. In the lower schools only about 1.5 per cent. were myopic and in the higher, about 3.5 per cent. making the average about 2.5 per cent. In the primary, he found no myopia.

Fox has examined the scholars of the Indian schools of Carlisle, and found only an average of 2 per cent. of myopia. Examinations have been made in various countries, such as North and South America, the British Isles, Germany, France, Switzerland, Russia; Italy, the Caucasian and Oriental countries, Norway and Sweden, Roumania, etc. The result of these investigations may be stated, in the language of Cohn, to be that "in the whole civilized world, in all nations, the number of the short-sighted increases with the demands which their school work makes, and from class to class."

The percentage of school myopes in our own country, perhaps, does not exceed an average of 25 per cent., but it is constantly increasing to correspond with the requirements of our advancing civilization. This comparative myopic infrequency need not, however, detract from national pride, when reflection is made upon the polyglot character of our citizens. Undoubtedly, statistics taken from native born Americans would increase the percentage, and perhaps enable the egotistical enthusiast of our soil to refute the statement that there is on the earth a more studious and intelligent race of people than in the land where the eagle flaps its wings, and the starry flag waves majestically in the wind.

The coincident occurrence of advance in classes and myopia is exceedingly interesting and instructive combined, as it is, with a diminishing hyperopia in almost exactly reverse proportions. In this connection I can not refrain from quoting the figures of Erismann who, in 1871, examined 4,368 St. Petersburg scholars. They are as follows:

Class . . . . .	1.	2.	3.	4.	5.	6.	7.	9.	10.
Myopia . . . . .	13.6	15.8	22.4	30.7	38.4	41.3	42.	49.8	41.7
Hyperopia . . . . .	67.8	55.6	50.5	41.3	34.7	34.5	32.4	36.2	40.

The almost invariable increase of myopia from class to class and the similar decrease of hyperopia is striking in its accuracy. The apparent discrepancies in the latter classes may be due to the fact that as a class approaches graduation its number usually diminishes, which would produce a different proportion in percentages. The table of Erismann practically corresponds with others prepared on this subject, and is an impressive comment on the effect of modern civilization on ocular refraction, and tends to confirm the belief that the very cause which produces myopia diminishes hypermetropia.

If the physical condition of a myopic eye is an elongated axis, what are the abnormal circumstances which produce such an elongation, irrespective of whether the eye has a natural myopic tendency or not? Most text-books furnish an explanation of this phenomenon, but the most comprehensive I find given by Fenner, and take the liberty of quoting his words: "They (the scholars) usually sit bending over a desk in a stooping position; the abdominal organs are compressed, preventing the free return of the blood from the head; the insufficient illumination at many schools and colleges necessitates the

bringing of the eyes very near the book, so as to obtain a larger visual angle; and as the book usually rests on a desk or table, the head has to be bent over; this posture produces an increased flow of blood to the eyes, while the higher degree of convergence necessary, causes an increased pressure of the lateral recti muscles on the equator of the globe; thus increasing the entire ocular pressure. The congestion of the fundus oculi causes softening of the scleral tissue, which gives way under the increased pressure, and the organ is elongated backward (posterior staphyloma); the other portions of the sclerotic coat are supported by the broad muscles. The retina is then pushed backward, behind the focus of the dioptric apparatus. When this condition once begins, all the causes which first gave rise to it act with increased force; there is a greater stooping posture necessary, because the eyes have to be brought still nearer to the object; an increased convergence is demanded, and the congestion of the fundus oculi increases; consequently, the softening processes progressively augment, causing the posterior portion of the sclerotic to yield more and more; hence myopia is usually progressive, particularly in the higher grades. There is a greater tendency to the development of this condition in youth from the causes above mentioned, because then the scleral tissues are softer and consequently more yielding than in later life. With the increase of age this coat hardens, becomes firmer and better able to withstand intra-ocular pressure; hence it is rare that posterior staphyloma, giving rise to near-sightedness, begins after the twentieth year of life."

Consideration must now be turned towards those conditions of school life which encourage and perpetuate the production and spread of myopia, and the first item that claims attention is that children should not be placed in school at all unless their general health is sufficient to endure the strain. It is unnecessary and space does not permit me to impress upon physicians the importance of this assertion, and the large influence exerted upon the eye by the general condition of the patient; but it is unquestionably imperative that we, as medical men, should emphasize the truth to the laity, and especially among those families committed to our care. We are, at present, dependent upon personal influence and the intelligence of those people not medically educated, to exclude from our schools those children not physically prepared to enter; but the time should and undoubtedly will come, when every scholar will not only be compelled to show a doctor's certificate before entrance, but will find it necessary to produce a similar document at the beginning of every school year.

What, then, are those conditions of school life which directly aid in the encouragement and perpetuation of myopia? First of all, the building itself should be so constructed as to present as few obstacles as possible to the proper exercise of the ocular function, and to give the pupils all the advantage possible in the way of location, space (inside and outside) heat, ventilation, plumbing, general cleanliness, water, basins and soap.

The building should be lighted properly and sufficiently, as there can be no question that a paucity of illumination necessitates a closer apposition of books, which in its turn means increased convergence and an encouragement of myopia. Just seeks

to controvert this statement by claiming no decrease in myopia in the new and well-lighted schools of Zittau, in Saxony; but the experience of others will scarcely support him in his position. For instance, in Coburg, Germany, 2,323 children were examined in 1874 and showed an average of 21 per cent. of myopia; the same number examined in 1877, after better lighting and seating had been provided, showed only an average of 15 per cent. of myopia. De Metz, of Antwerp, found only about 2 per cent. of myopia in well-lighted as against 5 per cent. in badly-lighted schools. Other statistics, even more striking than these might be produced to show the importance of proper illumination, but it is scarcely necessary as its principle must commend itself to the mind of any one who gives the subject even a casual observation.

The light in the school room should be direct, and not the indirect illumination from the walls of some adjoining building. It must be constant, and dependence should not be placed upon the immediate rays of the sun; for this reason, the windows should face the north. The most remote portion of the room should be bright, even on dark days, to the extent of receiving an illumination equal to ten candle power. Every scholar should, from his place, be able to see some portion of the sky. Light should come from the left, and as high above the scholars as the ceiling will admit. The total window surface should bear to the area of the floor a proportion of 1 to 5, and the panes should be as large as possible. It would be better if artificial illumination was never used, but if it is, a profusion of incandescent electric lights is the best substitute. They should be ample in number, properly shaded and brought sufficiently close to the desk to afford an abundant illumination. This light is much superior to gas, kerosene, etc., as its color is whiter, is capable of uniform distribution and concentration, and does not heat or vitiate the atmosphere.

The question of the construction of seats and desks is one of great importance. Seats should permit each scholar to squarely rest the feet upon the floor, thus favoring a natural and upright position; for this purpose, it will be necessary to provide seats of different sizes for individual pupils, who should be seated according to their height. The seats should have comfortable backs. The desks must correspond in size and have a slightly slanting top, and be far enough away from the head of the scholar (when sitting in an upright position) not to necessitate close approximation of the page of a book. Many seats and desks are so illy constructed for the needs of the individual student, as to just allow the head of the patient to emerge from the top of the desk, thus necessitating enormous convergence when attempting to study. These defects are usually observed in primary departments, where full-sized desks are used by very young pupils. Strict rules are enunciated by Fuchs and others as to the relation which should exist between the desk and seat. Fuchs says that "the proper position is that in which the shoulders and pelvis are parallel with the edge of the desk, and the head upright or bent but slightly forward. As to the construction of desks and seats, there must be several sizes, to suit scholars of various ages. The distance between seats and desks in the vertical direction, must be but little greater than the distance between the elbow and the ischial tuber-

osity. The edge of the desk must overhang the seat about two inches; the scholar can then sit upright."

Rohe does not think it necessary for the desk to overlap the seat, but says that "a line dropped from the near edge of the desk should strike the front edge of the seat."

The object, in any event, is, if possible, to prevent stooping and to compel the scholar to study in an upright position. Various apparatuses have been constructed for the purpose of forcing an erect attitude, but as yet nothing satisfactory and practical has been proposed.

Attention should be given to the distance and location of blackboards, to prevent their being placed at so great a distance from *any* scholar as to necessitate a strain in order to see, and to carefully avoid a position where rays of light will reflect upon their surface in such a manner as to obscure the characters inscribed thereon. Similar care should be given to the placing of maps, from which scholars from time to time are required to study. Some investigators believe in doing away with blackboards entirely, and substituting therefor white surfaces and black crayons, as black writing on white background can be read at a greater distance than the reverse. The same plan has been proposed and practiced in some schools with slates; white slates and black pencils are used on account of lessened reflection. Good results are claimed. Other investigators believe in ceasing to use slates at all, owing to the glistening surface, and substituting in their stead paper and pencil or pen, the paper to possess a non-glistening surface and be non-translucent.

School books should be of a size easily handled, and the paper should be reasonably thick, of good quality, and have a dulled surface; some authorities think that yellow instead of white paper is to be preferred. The Latin letters are best for all kinds of reading, and it is certain that if Germany would absolve itself from nationalism sufficiently to declare an emancipation from its miserable type there would be less myopia in the Fatherland. The letters should be well-printed, clear, distinct and large. Cohn insists that all books should be prohibited from schools in which smaller type is used than long primer, a less interval between the lines than one-tenth of an inch, a longer line than four and one-half inches, and more than sixty letters to a line.

The question of erect or slanting handwriting is one that is much agitated at present. Ellinger, in the first place, opposes the practice of inclining the copy-book to the right instead of straight ahead, feeling that it favors the development of myopia. However this may be, it is certain that there is variety in the opinions expressed relative to the preference as to erect or slanting writing, with the drift of sentiment favoring the former. Berlin favors the inclined writing, but he appears to be occupying a somewhat isolated position, as a tendency of opinion from Shubert, Manz, Königshofer, Seggel and others certainly indorses vertical handwriting. It is felt that the oblique system favors myopia by an unnatural position of the head, and by the fact that upright writing is usually clearer and more easily read than the reverse. Continuous work is detrimental to the health of the eye. This can be avoided in the school by often changing from one occupation to the other, as from desk work to recitations, and by frequent intermissions, during which time the rooms should be thor-

oughly aired. Matais claims that at the Military Prytanæum and at the School of Arts and Industry at Angers, myopia is relatively rare, although the hygiene is not better than in the colleges, because the interruptions in work are frequent, consisting in manual work, games or active exercises.

Unquestionably, much harm is done by indiscretion in ocular service at home. Granting that our directors performed an elimination of all existing school evils relative to ocular hygiene, there would still remain an element beyond their control in the abuses at home. Here we have a recapitulation of all the evils already enumerated in school life, to which others are added. Provisions are not usually made as to proper desks and seats, light and interruptions in work. Children are allowed much latitude as to what they read, and when and how they read it. Poorly printed novels are absorbed before and after going to bed, in sitting and reclining postures, by any light that happens to be convenient. In view of such abuses which will inevitably exist, especially among the poor and ignorant, the warfare against myopia is not of an encouraging character; but it does not absolve us from pressing the battle whenever the opportunity presents. If perfection can not be obtained, progress can at least be made, and much benefit will accrue from educating school directors, teachers and the laity who can, in their turn, perform a part in disseminating a knowledge of the subject among those who are less informed than themselves.

As a rule, children are sent to school too early in life, and too little attention is paid to the individual adaptability of the child for school life and its requirements. It is felt that a child must go to school at a certain age, irrespective of his physical condition, and such generalizing of educational methods is frequently followed by exceedingly detrimental results.

Children often go into kindergartens with perfect refraction, and acquire myopia before entering the primary department of the public school. The use of the eyes at a tender age, especially in those children inheriting a myopic, tuberculous or scrofulous tendency is exceedingly hazardous. Their tissues are soft, pliable and yielding, particularly where such parental predispositions exist; and the confinement and bad school hygiene, coupled with the desk and eye work incident to school life, unquestionably form a combination of circumstances conspicuously favoring the development of myopia.

Myopia is rare before the eighth year of life. Hypermetropia is the normal refraction of early life. Myopia usually begins about the tenth year and reaches its maximum at about the twentieth year. Statistics show that the less educated the nation, the more cases of normal refraction are found. Hence these early years of life should be guarded from the refining influences of intellectual advancement as much as possible, bearing in mind that it is better to devote our youth to laying the foundation of a strong constitution, and that the rural child, raised upon the farm, with practically no educational advantages until about the fifteenth year, often far outstrips his city rival whose life has been spent in kindergartens and other graded schools.

The question as to what shall be done with these children of perverted tendencies is one of great importance. Shall they be sent to the public school at

the average age, to be thrown into the common receptacle, to be assigned the same lessons, and to be treated in exactly the same way, as the youth of untainted health and robust constitution? Common humanity unhesitatingly answers in the negative. Such children should rather be allowed to spend their lives in the open air, with a judicious intermixture of properly assigned manual labor. Their early education should be religiously neglected, and every effort should be made to mitigate the unfortunate tendencies of birth by a physical rather than an intellectual life, spent preferably in the country, where the air is good and the surroundings healthy. Systematic study should not be begun until about the fifteenth or sixteenth year, after the body is thus strengthened, and the ocular tissues have grown firm and better able to resist the encroachments of myopia. Even now, it will be better to teach the child at home, or at some private institution, where its student life can be properly controlled.

It may be urged that such advantages are only for the wealthy, and the question may be asked as to what must become of the poor myope. This may be exceedingly pertinent, but it must not be forgotten that the compensations of life are somewhat evenly divided, and that myopia, is much more prone to occur among the wealthy and intellectual, than among the poor and illiterate; consequently the necessity for such restrictions in the early career of our youth will not so often be required of the latter class.

Can myopia be cured? This is a question which is forced upon us, and must be conservatively answered. When once thoroughly established, and decided organic changes have occurred, the probability is that with our present knowledge of the disease it can not be cured; it can only be alleviated. That by improved school hygiene, education of the laity, and careful and uniform correction of refractive errors, it is susceptible of material mitigation in a community, is amply proved by the careful and painstaking investigations of Risley and his associates in Philadelphia. But it must ever be borne in mind that the only reasonable hope for even partial emancipation must necessarily rest in prophylaxis, school hygiene, an intelligent coöperation of the laity, and a proper correction of the refractive error by suitably adjusted glasses.

But while the subject of myopia in youths is of signal importance, we must not lose sight of another class of perverted refractives, viz., the hypermetropes and astigmatics. These, it is true, do not possess that element of danger to sight found in malignant myopia, where the disease marches on to posterior staphyloma, detached retina and blindness; but it does mean much, in the possible intellectual progress of the individual, and the attainment of those heights of knowledge apparently demanded by modern civilization.

The myopic eye is often a strong eye, capable of performing much work at short range; but the hypermetropic or astigmatic eye possesses attributes quite the reverse, viz., comparative ease in distant service, but great inconvenience for close work. The hypermetropic or astigmatic youth suffers from those various symptoms, such as headache, eye-tire, etc., generally classed under the one term, asthenopia, and which have their principal origin in an overtaxed ciliary muscle. He goes to school, but takes no in-

terest in his studies; he is called idle, because he gives so little attention to his books; he is classed as stupid, from never knowing his lessons; he is thought to be a complainer, because he frequently has headaches; he taxes the patience of both teacher and parent, whose wonder is excited when the inane, idle, stupid, fault-finding child is transformed into a wide-awake, industrious, healthy student by the aid of a properly adjusted pair of spectacles. This is an experience common to every teacher or oculist; and the frequency of its occurrence should be an incentive to active efforts for relief on the part of those from whence relief must come. An important matter of this nature can not with safety be left to the laity to settle, for the laity is frequently ignorant, careless and impecunious. Some means must be devised by which an ocular examination of each scholar shall be a requisite for entrance into a school, and by which a repetition of such an examination must be made at stated intervals during the scholar's school life. Opinions differ as to the necessary frequency of such tests; some feel that they should be held every six months and others that annually will be sufficient. Either would be an improvement on the present system, where nothing of the kind is required.

In addition to this, provision must be made by which children who shall be adjudged to possess defective eyes, shall be required to produce a proper certificate from a reputable physician, before admission to the school is permitted. Such a specification would exclude work done by opticians, jewelry and department stores, etc.

The ideal method would be to have a competent physician appointed by the proper authorities, whose duties shall be to pass upon the eligibility of all scholars, both upon entrance and at stated intervals. This would, however, be open to certain objections. It would involve a salary which the different boards might be unwilling to pay, and would inevitably impair the efficiency of such a law, by a degeneration into political jobbery. Beside this, the appointee would undoubtedly be distasteful to many pupils or parents, which would constitute an obstruction to harmony and an embarrassment to the examiner.

In case such a method is deemed inadvisable, the next best procedure would be to require of each pupil a proper certificate from a reputable physician, stating the ocular condition of the applicant, with recommendations for relief if necessary. This, again, would be opposed by the people as compelling an ocular examination where it is perhaps unnecessary, thus incurring a useless expense to parents or guardians. It is true that a combination of both of these methods might be adopted, and a law passed requiring that each pupil shall pass an ocular examination, by a physician employed by the Board of Education, but leaving it optional with the parent or guardian whether the child shall be passed upon by the school examiner, or taken to a physician of recognized standing whom they themselves shall select. This would be a compromise measure but would still be open to the combined objections of both procedures in mitigated form.

There is another method of dealing with the subject, proposed by the writer, which may not be considered sufficiently stringent and scientific for enthusiasts on the matter, but which the writer believes to be all that can be accomplished at present and may pave the way for something more energetic in the

future. It can be executed at practically no expense to our school treasury, will but seldom cause useless expense to parents and guardians, can be universally applied and, if thoroughly accomplished, will give general satisfaction. The idea is simply to have a physician of recognized ability deliver a lecture or talk on the subject to the principals of the city schools, once a year, just preceding the opening of the schools. This talk shall include plain and comprehensive remarks on the anatomy and physiology of the eye, refraction, and how to use but not abuse the eyes in school and home work. It will also instruct the principals how to test the eyes, in accordance with the subjoined scheme. Besides this, printed directions for testing the eyes shall be given to each principal, which might read something like this:

#### INSTRUCTIONS FOR EYE EXAMINATIONS.

The examination should be made privately and singly, in a room apart from the general school session.

Place a card of Snellen's Test Types on the wall in a good light; do not allow the face of the card to be covered by glass.

The line marked xx (20) should be seen at twenty feet, therefore place the pupil twenty feet from the card.

Each eye should be examined separately.

Hold a card over one eye while the other is being examined. Do not press upon the covered eye, as the pressure might induce an incorrect examination.

Have the pupil begin at the top of the test card, and read aloud down as far as he can, first with one eye and then with the other.

If the pupil can read xx (20) test type with each eye and does not, upon inquiry, complain of tired and painful eyes or headache, he may be admitted to school; but if he can not read xx (20) test types with both eyes, or complains of tired and painful eyes or headache he should be sent home with a card of information to the parent or guardian.

This card might read as follows:

MINNEAPOLIS, Oct. 1, 1894.

Dear Sir:—Your son, John Smith has been examined by me this day as to the condition of his eyes.

I believe it to be advisable for him to consult a physician of recognized standing, from whom he must bring a certificate, stating it to be wise for him to continue his studies. Some regular oculist is recommended.

Without such a certificate he must be denied admittance.

Respectfully,

MARY JONES,

Principal of Douglas School.

This scheme possesses many advantages. The physician selected to deliver the lecture or talk to the principals, would undoubtedly be glad to do so gratuitously, and much useful and practical information could be deduced therefrom, which would react most favorably on the scholars.

The test cards could be procured at a nominal cost, not to exceed 25 cents for each school, and the printed cards of instruction for principals, and the cards to be sent the parents or guardians would cost but little. The expense, therefore, of the entire outfit would be so small as to be unobjectionable.

Then the test is so simple and easily accomplished, that any one of sufficient intelligence to be a principal of a school could soon master it and examine the pupils with such ease and rapidity that a large school could be tested in a very few days. An average of two or three minutes to each pupil would be more time than is necessary, if systematic arrangements were made.

The writer is well aware that such an examination is not ideal and is open to objections; but it is better than nothing, is fairly sufficient, can hardly antagonize interested parties, can not savor of medical favoritism, involves practically no expense, and is so sim-

ple and practical as to commend itself to all parties concerned. In large cities the scholars would unquestionably consult oculists instead of general practitioners, and where the latter were consulted the patient would probably be referred to the former. Those not financially situated so as to render it possible to consult an oculist in his office could procure equally good services at some dispensary.

If such a law were enacted in small towns, at least one or two resident physicians would find it profitable to become somewhat familiar with the subject; or children could be sent to a neighboring city for advice; or, if a fair number of cases were to be examined, an oculist could undoubtedly be procured who would be glad to make a trip into the country for a few days to examine defectives in a tier of towns.

The writer believes this to be the only plan for relief that can be procured at present, and as such trusts it may meet with the approbation of those interested in the subject.

## TWO EXAMPLES ILLUSTRATING POSSIBLE SOURCES OF ERROR IN THE DIPHTHERIA CULTURE TEST.

BY A. P. OHLMACHER, M.D.

BACTERIOLOGIC LABORATORY, MEDICAL DEPARTMENT, UNIVERSITY OF WOOSTER, CLEVELAND, OHIO.

The diphtheria culture test, valuable as it is in clinical diagnosis, is not infallible. Indeed it would be strange to find it an absolutely certain method, dealing as it does with forms of life confessedly prone to sudden, and at present, inexplicable variations. The following examples are cited because they illustrate some puzzling occurrences in routine bacteriologic work, and because they impress us with the necessity of due scientific conservatism in even so apparently simple an operation as the culture test for diphtheria.

The first case came to notice in Chicago, in February, 1894. A Prudden swab was kindly brought to the laboratory by Dr. J. B. Loring, of Valparaiso, Ind. The swab was obtained from a case which had all the clinical features of true faucial diphtheria, and the provisional diagnosis of diphtheria was strengthened by the fact that diphtheria was endemic at the time in Valparaiso, and that a clear history of exposure could be elicited.

An examination of several cover-glass preparations from the twenty-four hours' culture on Löffler's medium showed only micrococci from this case, and a diagnosis of pseudo-diphtheria was made; much to the surprise of Dr. Loring. Four days after the first examination I happened to take up the tube of Löffler's serum which had remained in the incubator since the first preparations were made. It was noted that the macroscopic appearances of the culture had changed, for while it had presented a yellowish color during the first two days, it now took on a dirty grayish tinge. Microscopic preparations from this four days' culture revealed bacilli in predominating numbers, resembling in every way the picture usually obtained in eighteen to twenty-four hours after the inoculation of Löffler's medium with the material from genuine diphtheria. No attempts were made to isolate the bacillus, so that, save for its strikingly characteristic morphologic resemblance, it is impossible to say that it was a true *Bacillus*

*diphtheriæ*. On this account this example was dismissed for want of corroboration until a second, and more peculiar experience again brought it to mind.

On Dec. 20, 1894, through the courtesy of Dr. L. B. Tuckerman, of Cleveland, I received a Prudden swab from the throat of a girl, a domestic, who exhibited certain suspicious symptoms of diphtheria. She had considerable fever, some pain and extensive redness in the throat, swollen tonsils, and a small, isolated patch of grayish membrane on the left tonsil. The patch of membrane did not increase much in extent; the patient was much improved on the second day; and was pronounced well after the third day. About a week later the girl again consulted Dr. Tuckerman for a debility and depression which had persisted since the acute illness.

A tube of Löffler's medium was inoculated as soon as the first swab was brought to the laboratory. After twenty hours in the incubator the surface of the medium was covered with an uneven grayish coat resembling an early culture from true diphtheria. The usual microscopic examination of stained preparations was made, and as great numbers of irregular bacilli with the morphologic features of the typical Klebs-Löffler bacillus presented themselves, together with a few micrococci, a diagnosis of true diphtheria was made. The next day another swab was obtained from the patient, and on subsequent examination only micrococci were obtained from it. This happened also with a swab obtained on the third day of the disease. Due care was taken in the use of disinfectants in the throat before the swabs were obtained; and there was nothing in the treatment which could account for the strange behavior of the bacteria in this case. The *Staphylococcus pyogenes aureus* was subsequently identified as the predominating coccus in the cultures obtained from the second and third days. The Löffler's medium employed in the course of these experiments was all of one batch, and was found by numerous control experiments to be above suspicion.

A scratch attenuation on a plate of Löffler's medium was made from the first culture tube of this case on December 9. Colonies of considerable size developed in twenty-four hours at the incubator temperature, and cover-glass specimens from several of these colonies showed only micrococci, notwithstanding the fact that the mother culture still showed the bacilli noted in the first examination, in great numbers. In thirty-six to forty-eight hours the colonies on the plate assumed a pronounced orange-yellow color, and transfers from these colonies to gelatin tubes gave a liquefying growth resembling the *staphylococcus aureus*. In fact, this species was subsequently isolated and identified in detail.

A second scratch attenuation on Löffler's medium from an isolated twenty-four hours colony on the first plate also gave micrococci that proved to be the *Staphylococcus aureus*, though the second plate did not exhibit the subsequent peculiar behavior observed on the first one.

After two or three days the plates were removed from the incubator and set aside at the room temperature. On December 24, fifteen days after the scratch attenuation, a striking change in color was noticed in the colonies on the first Löffler plate. The colonies were no longer orange-yellow, but grayish or white. These altered colonies were now examined microscopically and gave vast numbers of bacilli, closely resembling the bacilli seen in the original culture tube,

though staining more faintly. In order to watch the development of these bacilli, another scratch attenuation was made from the original tube culture on a plate of Löffler's serum. For six or seven days, at the room temperature, the growth on the plate, both the confluent lines of the first scratches, and the isolated colonies, exhibited the orange-yellow of the *Staphylococcus aureus*; and only micrococci could be discovered in stained preparations. Gradually, however, the white growth appeared, first at the edges of the confluent lines, and then at the periphery of the isolated colonies until, at the end of two weeks, the yellow color was entirely lost; and the grayish or white colonies gave hosts of bacilli and very few cocci, in stained preparations. Curiously enough, in both of the plates which underwent this transformation, every colony, either isolated or confluent, was overgrown by the bacilli.

After these failures to separate the cocci and bacilli by the scratch-plate method, several attempts were made to effect separation by the ordinary dilution-gelatin-plate method. This was impossible, however, on account of the rapid liquefaction induced by the *Staphylococcus aureus*, as the plate ran down before any other growth appeared. Agar plates have not been tried up to the present time.

An attempt to explain the results of these experiments presents many difficulties. At first sight it would seem easy to assume that, since the bacilli on the plates cropped out only at a late date, and at the room temperature, they must have belonged to some slow growing saprophytic species. But it must not be forgotten that in the mother culture from which the plates were prepared, bacilli, indistinguishable morphologically from *Bacillus diphtheriæ*, appeared promptly in twenty hours at the body temperature. Further than this, the remarkably close association of the *Staphylococcus aureus* with this bacillus which absolutely refused separation by the scratch-plate method, and by the gelatin-plate method, can not be readily explained, and if it does nothing else, this occurrence forcibly impresses upon us the inadequacy of the plate method of separating bacteria. Then there remains for explanation the fact that in three swabs on three successive days from the same patch of membrane in a sore throat, diphtheria-like bacilli appeared only in the first culture, and micrococci, consisting principally of the *Staphylococcus aureus*, appeared in the other two cultures. The most probable assumption that suggests itself to me is that this bacillus, which was morphologically identical with the *B. diphtheriæ*, was forced to undergo these peculiar changes, both in the throat of the patient, and on the culture media, as a penalty for its symbiosis with the *Staphylococcus aureus*.

## TOXICS.

BY WM. F. BARCLAY, M.D.  
PITTSBURG, PA.

A poison is a substance, which when taken into the system is either absorbed or by its thermal action on the parts with which it is in contact produces deleterious effects. It may seem strange that almost all toxics are innocent, until they reach the circulation of the blood. Their slow or rapid absorption largely determines their deleterious effects upon the system. In our observations we are reminded from time to time of the idiosyncrasies of individuals and we sel-

dom inquire into the causes of these peculiar conditions. It is generally attributed to a perversion of the nervous system, but in truth is caused by a rapid absorption of the poison and is modified by the power of resistance inherent in the individual. Hereditary predispositions and peculiar cachexias in persons are dissimilar conditions, and are in no sense identical. Heredity has not been defined satisfactorily, but the conditions of progenitors are transmitted in an attenuated form, which underlies their maladies.

When disease is engrafted into the organism it destroys the equilibrium of the entire physical life, and there is a want of coördination and harmony that is essential to perfect development and health. The continued multiplication of these distorted and diseased germs can in no way be more advantageously studied than by the observance of the results that follow. The non-observance of this law enfeebles and annihilates entire families and races. As to cachexias, it is a law of nature throughout the animal and vegetable kingdoms that the multiplication of likes tends to weaken organic life and, on the other hand, that the aggregation of dissimilars strengthens the protoplasmic results of differential unions. The non-observance of this truth produces results to which we apply the word cachexia. In its application to animal life, it is so well understood and applied in the union of the sexes, that the consequent results are most advantageous. The same principles are applicable to man in his protoplasmic development, and if properly studied and understood are of the most benign character as to perfect physical development. The vulgar opinion prevails that hereditary diseases are innate and that they lie dormant for a time and then, as it were, explode and destroy their victims. This doctrine is as false as a general rule, as it is ridiculous, as simply a predisposition is transmitted. Were it true, all such weaklings would die in infancy. It would be infinitely better for all such to die in babyhood than to live and suffer from inherited disease. The great desideratum for the educated and enlightened part of the human race is to consider this truth and put it into practical use, so far as the health, intellect, strength and well being are concerned in the multiplication of the race.

It is not difficult for the acute and careful observer to indicate the affiliations that will in a general way insure the best results. Divine as well as human laws condemn consanguineous marriages on account of their painful results. This great truth has been taught by the most careful, aggressive and learned physicians and surgeons, down through the decades, that syphilis and scrofula are identical. The views of the immortal Dr. Samuel D. Gross have been constantly with me, in an experience of over twenty-eight years in the practice of medicine, and have been verified in my observations to my entire satisfaction. That the toxic germs of syphilis are transmissible in the various stages of the disease is incontrovertible and undeniable. It is probable that there is a living germ for all diseases, and as our knowledge increases upon this subject we will be enabled to prevent and cure many diseases that are now believed to be beyond prevention and remedial influences. When hereditary disease conditions appear and toxic causes are present, they find an easy access into the system and suitable influences for their propagation. The blood is the life of the body and constitutes about one-fifth of its entire weight, which enables us to

understand how deleterious must be the entrance of toxics into the circulation, and their effects upon the economy of life.

The germ theory of intoxication is so well established that there are few members of the medical profession who deny or question its correctness. Toxics enter the circulation of the blood and their action on the normal cells produce toxins and the multiplication of these products bring on pathologic conditions. Nothing is more easily demonstrated than that the emunctories throw off toxics. All excrementitious matter when re-introduced into the circulation is poisonous; urine, bile, feces are poisonous and become more so after exposure to the air. In diseases many things have to be taken into consideration—the individual, age, sex and other conditions, as well as his environments. We observe at once upon the entrance of a toxic into the circulation of the blood that all the functions of the body are impaired to a greater or less degree, and that definite poisons are quickly formed such as ptomaines, leucomaines and others which are nothing more or less than an altered nutrition. The vital forces are at once disturbed or arrested. Primarily the circulation, and secondarily the nervous system are impaired, and a condition termed shock is superinduced. This state is a most interesting study to the pathologic student, difficult of comprehension and explanation. It may be remarked that all the vital forces are similarly affected at the same time. The *vis medicatrix natura* can at no time be more carefully studied and understood than when the vital forces struggle for an equalization, and restoration of the normal conditions.

In the state of shock, nature seems intent upon relieving herself of all effete matter, by the discharge of the contents of each viscus of the body. All such efforts should be assisted by artificial means in restoring a healthy condition. Vigorous health and strength are maintained by proper food, perfect digestion with healthful environment. In the germs of organic life, disease takes its beginning by the introduction of toxics; thereby the blood is changed and disease set up. Certain predispositions are inherited and the subject rendered more easily affected by specific toxic influences. That all persons exposed to the same influences are not affected is because of a weakened vital condition thereby rendering them more easily poisoned. All are impressed by the same specific toxic influence under similar circumstances. Molecular and cell life are great mysteries of which we know very little. When the physiologic laws of cell life are properly considered it is evident that the mineral and animal constituents are alike being prepared for the building up of the different tissues that constitute the body.

We begin life by the blending of cells that are healthy or diseased which determine the ultimate result. Farther on we are taught that the blood corpuscles are formed in the spleen and long bones, but I would inquire how they are formed, when neither spleen or bones are present in embryonic development?

In organic growth the circulation is first established, the nervous system follows on, and seems to regulate the entire development of the body. The truth I would establish is that disease begins in the cells and that all treatment employed must be directed and applied to the circulation of the blood, that while we may differ as to the utility and impor-

tance of remedies, we can not gainsay their benign influences when wisely and judiciously administered in diseased conditions. That a physician can practice medicine and deny the value of scientific medicines is the surest evidence of that want of knowledge to prosecute the work of the sacred art of healing. Toxics are poisons that produce conditions peculiar and distinct in their final results. We are fully aware of many different forms of toxic life, but at a great loss to know by what means they obtain entrance into the body and circulation. We know that food, drink, and the air we breathe are vehicles through which the germs reach the circulation. Contact is necessary; that most infectious toxic germs may be deposited in various stages of incubation, but are the same in each disease. Toxics may be classified as contagious, infectious, malarial and thermal. The vitality of disease germs is variable and in general terms can not be specified. The germs of many contagious diseases have been known to retain their vitality for long periods of time, and to readily prove toxic under favorable conditions. Smallpox, phthisis pulmonalis, scarlet fever, diphtheria, measles and many other diseases may be cited as illustrations of the viability of toxic germs.

It is true that in the organism there is a continual tendency toward toxemia from the normal physiologic processes, which is counter-balanced by the excretions of the body. If for a short time you modify or arrest the eliminations by emunctories of the body, the whole economy of life is disturbed, pathologic conditions are set up and disease established. Elimination must take place through five excretory offices; a disturbance or disarrangement of one or more destroys the vital equilibrium of life. The non- or partial elimination of the effete products of nutrition and disintegration generates toxics. The vital forces are a constant barrier through their tendency to equalization of the constituents of the protoplasm of the blood against the deleterious effects of toxics. The abnormal albumens escape by the kidneys, and destroy the renal epithelium; thereby inflammatory diseases of these organs are set up. It may be stated that leucin tyrosis, and many other toxic products of the liver are the results of imperfect excretion.

The body in a normal and pathologic state is a receptacle and laboratory of toxics. I am impressed, while considering this subject, that by the cravings of the appetite, nature in this way points out that which she in a general way needs for her sustenance. It has been a rule of practice with me to permit the sick to eat and drink that which the appetite craves. I have as yet to see good reasons for changing this course of practice.

There must be a perverted nutrition in order that infection can take place in man, with a single exception, and that disease is syphilis. In order that disease can attack and harm the human body it must first be prepared for it by pathogenic influences. If it were not for this necessity the human family would have perished from off the earth before this time in the world's history. Nutrition is life, and all influences that tend to destroy must first impair it. We must study nutrition in all that pertains to it in its equilibrium; any disproportion in its constituents impairs and unfits it for its normal use. Perverted nutrition leads to the formation of new substances which become toxic. That much can be done to prevent and cure disease by change of location is

well established. Many lives are saved and much suffering averted by careful and accurate knowledge of climatic influences. Therapy is too general in its tendencies. A few remedies properly prepared and wisely administered give the best general results.

It is to be lamented that venesection is almost forgotten and neglected in the treatment of diseases. We are taught that our civilization has brought about systemic conditions that forbid the use of the lancet. Is it true that we can bring about the same results by our modern therapeutics? We may enumerate a few therapeutic agents, mineral and vegetable, that aid nature in overcoming the pathologic results superinduced by the introduction of toxics into the circulation of the blood. Gold, arsenic, mercury and iodine with their compounds, and opium, Peruvian bark and their alkaloids, with digitalis, aconite and veratrum virid.

That the practice of medicine is becoming more empirical in the age in which we live, is not true but, on the contrary, is broad and general in research as to causation and treatment. Research as to the origin and effects of diseases is becoming more general and characteristic. Lesions of the body are more carefully and scientifically studied each year, as we bring to our aid helps in the investigations now going on in our laboratories that simplify and determine the causes of disease, as well as the changes it brings about. We now definitely know the causes of many of the most fatal maladies, and apply prevention and cures that modify their ravages, to a large extent, and annually save thousands of lives and prevent much suffering. *Contagium vivum* of the contagious germs is beyond all doubt established. The implantation of vegetable organisms in healthy man, their multiplication in the individual infected and their transmissibility to others producing a disease similar to the original, is the final termination of theories on the subject of contagion.

Parasiticism is established in a number of diseases in man, for instance, charbon, glanders, phthisis pulmonalis, gaseous, gangrene, blenorragia, erysipelas, septicemias, as well as in animals and fowls, swine fevers, symptomatic pustule and cholera. Each disease is produced by a microbe, and we must wait for the discoveries yet to be made in microbiologic research for those not already discovered. The dissemination of microbes is universal, and that all are not alike affected is not so easily explained. To a healthy man, the microbe is less likely to be dangerous than to one not in good health, as the individual circumstances are less favorable for development. A modification antecedent in nutrition, renders infection more probable. Fatigue, exposure to cold and wet, severe excitation, bad food and air and many other influences are disease developing causes. Hygienic causes such as excesses in eating, drinking and venery, with loss of rest and bad air develop nutritive disorders in which the cells are perverted, a tainted nutrition set up and among these cells the generative elements of ovule and spermatozoon are formed and by their union will cause the beginning of a new creature whose cells must partake of the disorders of its antecedents. In the entire domain of pathologic research, we know the least about the toxalbumens. As yet our knowledge of the normal physiologic albumen, in health, one of the most important constituents of the blood, is very limited. It is accurately known when there is a disproportion of the

red and white corpuscles, as well as the normal fibrinization of the vital fluid, the toxalbumens prevent the formation of the red and white corpuscles. It may be here observed that in certain pathologic conditions there seems to be a third corpuscle or something that very closely resembles it. In the field of antitoxic treatment, there has been in the past fifteen years a large amount of investigation and laborious work in laboratory research, and while we can but deplore the futility of results, so far as toxin treatment has advanced, we must very highly appreciate the advances so far as causation of diseases is concerned. While it is perhaps too early to draw positive conclusions as to the method of treatment, it may be fairly stated that thus far permanent results are disappointing. Remedies thus far highly beneficial have been obtained from the mineral kingdom, so far as prevention and cure have prevailed.

Prevention is better than cure, and each year the profession of medicine is accomplishing more in this direction. We are enabled by quarantine to circumscribe plague districts, and by cleanliness and disinfection to prevent the spread of disease. The good accomplished in this way is inestimable, and the number of lives annually saved can not be conjectured. The pestilences transmitted from foreign countries under our present immigration laws are a constant menace and danger to our people. I am unable to recall a single instance of the transmission of pestilential diseases from our country to foreign countries.

The constant vigilance on the part of physicians as to the prevention of the spreading of disease in different ways is not estimated or appreciated by the people. We seldom hear it referred to but, on the other hand, the profession is frequently charged with carelessness in carrying diseased germs to their patients. Great care should be exercised in treating patients suffering from contagious and infectious diseases lest the germs might be carried in this manner. From these considerations it appears that when the toxic causes are present, their ready transmissibility and easy access to others, under suitable influences for their propagation, can not be overestimated. It is probable that there is a living germ for all diseases, and as our knowledge increases we will be enabled to prevent and cure many diseases that are now believed to be beyond prevention and remedial influences.

The profession of medicine is now tending toward specialism, perhaps not in some branches to its best interests, but it certainly is true that the bacteriologist is entitled to a more prominent place than he has yet attained. The sciences of bacteriology and therapeutics keep pace with each other and annually many thousands of lives are saved and much suffering averted. The causation of many diseases is beyond our present comprehension, yet the processes following primary elementary dystrophies, nerve reaction disturbances are antecedent to nutrition and infection. Diathesis is a permanent disturbance brought about by the blending of germs that provoke and maintain pathologic processes. It is generally considered a morbid temperament dwarfing all the powers of animal life.

In conclusion, the laboratory research and scientific investigation of toxics as to their propagation in cultures and their introduction into the bodies of man and animals for scientific results are the labors of the bacteriologist. We do not present you the labor of a volume but rather a short review of the

scientific work that has been done in this most interesting field of thought, and its application in the practice of medicine at the present time.

North 21st Street.

## FREE HYDROCHLORIC ACID—IS ITS ABSENCE FROM THE STOMACH A SIGN OF CANCER?

BY RICHARD B. FAULKNER, M.D.

ALLEGHENY, PA.

It is important to know whether free hydrochloric acid is secreted by the stomach. It is important to know whether its absence from the stomach is an indication of cancer of that organ. Prof. Wm. Osler, of the Johns Hopkins University, in his excellent work on "The Practice of Medicine," published in 1892, states that, "great stress has been laid of late years upon the absence of free hydrochloric acid in the secretions. As an outcome of the enormous number of observations which have recently been made, it may be said that free hydrochloric acid is absent in a majority of cases of cancer of the stomach. This defect is associated with impairment of the secreting function of the organs. The examination should be made repeatedly by the methods already referred to, and with our present knowledge the persistent absence of HCl in the stomach contents, taken in conjunction with other symptoms, may be regarded as highly suggestive of cancer. As Kinnicutt expresses it, 'the presence of HCl in the stomach in repeated examinations in doubtful cases is of the greatest diagnostic value, and points very certainly to absence of cancer.' Rosenheim has very recently shown that in cases in which cancer develops in the base of an old ulcer HCl may be present throughout the course."

Kinnicutt's statement can not be proved.

Rosenheim contradicts Osler. If "the absence of free HCl is associated with impairment of the secreting function of the organ," then why should a cancer situated at the base of an old ulcer form an exception to the rule when, as a matter of fact, the ulcers themselves impair and often destroy the secreting function? If Rosenheim is right, then free HCl is absent in cancers not seated at the base of old ulcers. If cylindrical-celled epithelioma and encephaloid cancers constitute a major portion of all cancers affecting the stomach, as is stated by Osler, and if they have always a particular tendency to develop at the site of ulcers, scars and injuries, according to Paget, Holmes, Erichsen and others, then, if Rosenheim is any authority, are we not to conclude that free HCl must be present in the majority of cases of cancer of the stomach?

To obtain the gastric fluid for chemic examination, Ewald's test-breakfast is advised by the leading text-books. This consists in giving a roll of white bread and one glass of water or a cup of tea. One hour later, the contents of the stomach are removed with a rubber tube. No rule, no instruction of any kind, is given in any text-book whereby we may positively know that the stomach is actually empty at the time the test is applied. And in cases of stenosis of the pylorus it is not only possible, but probable, that the stomach is not entirely empty. However, as a result of Ewald's test, "free HCl should be present, but lactic acid absent." (Prof. Wm. Pepper, "An American Text-book of the Theory and Practice of Medicine," published in 1894, vol. II, page 735). "Should con-

tain free hydrochloric acid; should not contain sufficient lactic acid to be recognized by the ordinary tests." (Osler, page 345). Does it not forestall the judgment to proclaim what *should be* present? The usual object of a test is to ascertain what *is* present.

Physiologic chemistry contains no problem more difficult than the determination of free hydrochloric acid in the gastric juice. Many authors assert its presence as a normal constituent, and of the analyses *quoted*, in Foster's "Physiology" for example, no two agree; they vary in the proportion of free acid all the way from .05 to .5 per cent.

The method of chemic analysis commended and relied upon by two of America's foremost teachers let us critically and briefly examine. "The best and simplest test," says Osler, "is that of Gunzburger: phloroglucin, 2; vanillin, 1; absolute alcohol, 30. To a drop of the gastric contents (better filtered) add a similar quantity of the reagent on a porcelain plate. On evaporation gradually to dryness over a flame, a beautiful rose-red color begins to appear at the edges if HCl is present. This is merely a test for a free mineral acid, but HCl is the only one present in the gastric juice. This test is extremely delicate, and is not interfered with by albuminates, acid salts, or organic acids." (Pepper, vol. II, page 735). The simplicity of Gunzburger's proceeding would be valuable if the test were reliable. But color tests as a rule are unreliable; and this of Gunzburger forms no exception.

*Gunzburger's test is not a test for free hydrochloric acid.* It will show the presence of free HCl where none existed previous to its application. Sodium chlorid is a constituent of the gastric juice. If lactic acid is present in the stomach contents, evaporation of a drop over a flame will concentrate the acid, which will then attack the sodium chlorid and form free HCl. Other concentrated acids will do the same.

*Gunzburger's test is not a test for a free mineral acid.* The identical rose-red tint will be obtained when no free mineral acid is present. Many foods that contain no acid, mineral or other, taken into the stomach will produce precisely the same rose-red tint of the supposed test. Again, there are acids formed in the body, not mineral acids, that will produce the same brilliant rose-red tint of the so-called test. For example, in those who possess the oxalic diathesis, oxalic acid is formed in the living body by oxidation.

Oxalic acid decomposes dry sodium chlorid when heated, with evolution of hydrochloric acid (Fownes' "Chemistry," page 658; Brande and Taylor, page 384).

Oxalic acid responds perfectly to the Gunzburger test in the presence of sodium chlorid. Oxalic acid exists in many of our food plants, as a salt of potash, and is widely distributed in vegetation. Bin-oxalate of potash is found in common sorrel, wood sorrel, and in garden rhubarb associated with malic acid (Fownes, page 659). It exists in great abundance in tomatoes and in many other acid fruits.

*Gunzburger's test is utterly, absolutely worthless*, as proved by the following experimentation:

Experiment 1. With a minute quantity of bin-oxalate of potash, sodium chlorid and lactic acid, Gunzburger's test yields on evaporation over a flame a rose-red tint identical with that produced in the presence of free hydrochloric acid.

Experiment 2. With a minute quantity of bin-oxalate of potash, sodium chlorid and tartaric acid,

the same brilliant rose-red tint is obtained when evaporated over a flame in the presence of the Gunzburger test solution. Baking powders contain tartaric acid. A biscuit or a roll of bread, as in the Ewald test-breakfast raised with baking powder, contains tartaric acid. And wines contain tartaric acid.

Experiment 3. Bin-oxalate of potash and sodium chlorid, dissolved in water, and Gunzburger's test added, yield when heated over a flame a rose-red tint identical with that produced by free hydrochloric acid.

Experiment 4. Tartaric acid and sodium chlorid, dissolved in water, and Gunzburger's test added, yield when heated over a flame a rose-red tint identical with that produced by free hydrochloric acid.

Therefore, if a patient suffering from a cancer of the stomach were to eat a little rhubarb or tomato or take a drink of wine and Gunzburger's test were to be applied to his gastric contents, it would be conclusively proved that he had no cancer!!

Uncombined hydrochloric acid is not found in nature, except as an occasional volcanic product (Brande and Taylor, page 216). No mineral acid is necessary in the process of digestion. Pavy ("Food and Dietetics") states that HCl has no particular property in rendering the digestive power of the gastric juice more energetic. The presence of free hydrochloric acid as a normal constituent of the gastric secretion has never been demonstrated. The only way to *positively prove* its presence is to separate the acid; just the same as you would be required to separate arsenic from the contents of the stomach in a supposed case of poisoning by that mineral.

The absence of free hydrochloric acid as a normal constituent of the gastric secretion has been repeatedly proved by the most competent authorities, including such original investigators as M. Claude Bernard, the profound French physiologist, Robin, Verdeil, and Professor Rogers, the able chemist of the University of Pennsylvania. Our illustrious American physiologist, John C. Dalton, taught that lactic acid is the normal acid constituent of the gastric secretion. He neither taught nor acknowledged the presence of free HCl.

Prof. Carl Seiler records a series of highly interesting experiments in the *Philadelphia Medical Times*, Feb. 6, 1875, which go far to prove that no hydrochloric acid is present in the gastric secretions.

The most remarkable line of experimentation ever conducted upon the gastric secretion remains unnoticed by any author, compiler, or text-book, within our knowledge. These extraordinary experiments seem to have been forgotten. These experiments, unquestionably the most exhaustive, as well as the most authoritative upon this subject, were conducted under circumstances both exceptional and fortuitous, in the physiologic laboratory of the University of Pennsylvania. The gastric contents were those of a criminal (Heidenblutt). He was of strong physique, and was executed two hours after partaking of a hearty breakfast. Immediately after the execution, his stomach with its contents were removed to the laboratory of the University. The lining of the stomach was carefully scraped, and this with the contents of the stomach were macerated, filtered and distilled. The examination was made by Robert M. Smith, and to quote from an article in the *Philadelphia Medical Times*, Feb. 13, 1875: "The following deductions confirm entirely those obtained by Profs. F. G. Smith

and Rogers of the University, from the analysis of the gastric juice of Alexis St. Martin:

"1. The gastric juice presents an acid reaction both before and after filtration and distillation.

"2. The acidity in this instance was not due to the presence of hydrochloric acid.

"3. Lactic acid did exist.

"4. Acid phosphate of lime showed no evidence of its presence.

"5. Neutral phosphate of lime did exist, and was held in solution by the lactic acid.

"I would take this opportunity of expressing thanks to Mr. Geo. Hay, a member of the class, and a gentleman of great experience as an analytical chemist, under whose careful supervision these experiments were conducted." Hay states that "free HCl is never present in the human stomach, unless introduced from without; that it would seriously damage it if present; and that it is impossible for it to be found in the stomach, for the reason that its liberation from a salt of any kind requires the presence of a concentrated acid, and any concentrated acid in the stomach would quickly destroy the organ. Concentrated acids are not secreted by the stomach. Free mineral acid is not a product of the stomach of man or animal. Its absence is not a sign of cancer." The researches of Bernard, Robin, Verdeil, Dalton, Smith, Rogers, and Hay, all original investigators, entirely agree.

## THE EARLY DIAGNOSIS OF CARCINOMA OF THE STOMACH, WITH THE BACTERIOLOGY OF THE STOMACH CONTENTS.

BY FENTON B. TURCK, M.D.

PROFESSOR OF DISEASES OF THE STOMACH AND INTESTINES, ATTENDING PHYSICIAN TO THE COOK COUNTY HOSPITAL, CHICAGO.

The product formed in the growth of carcinoma of the stomach—whatever it may be—seems early to alter the gastric, secretory and motor functions.

The mucous membrane is markedly affected by this product, so that even before the complete suppression of HCl and other secretory changes have occurred a soil is rendered fertile for the growth of microorganisms, especially the bacterium lacticus and in many cases investigated, seemed the predominating microorganisms.

In the Chicago Post-Graduate Medical School, clinic (on diseases of the stomach and intestines), the Cook County Hospital clinic and in private practice, it is my routine custom to make microscopic slides in almost every case stained for the detection of bacteria. In selected cases of various gastric diseases, pure cultures are made to determine as far as possible the predominant germs.

The various cultures are secured from the mucous membrane, by using a revolving sponge introduced into the empty stomach. This instrument is named the gyromele (revolving sound) which for bacteriologic purposes is inclosed in a sheath until it reaches the stomach, to prevent contamination from the mouth and esophagus. Revolutions are produced by an apparatus not unlike a surgical drill, while the sponge in the stomach revolves and removes the adherent material from the mucous membrane for bacteriologic investigations. The description of this instrument with methods of bacteriologic study and investigation will be published in the *Wiener Medical Wochenschrift*. (See note.)

In all cases of carcinoma of the stomach, numerous colonies of a large variety of germs are found. They seem to revel in this superb culture bed. It is one thing to find stray germs in the lumen of the stomach which may occur in health (as is often the case in removal of stomach contents through a tube) and another to find the colonization of germs adherent to the mucous membrane of the walls of the stomach. The whole mucous membrane of the stomach under the changed conditions, is transformed into a large plate culture, so to speak, with a most perfect nutrient media, and unless other evidence is presented to contradict, we shall be forced to consider the infection a powerful and prominent causal factor in producing the rapid alteration of function—the disappearance of HCl, the ferments and final atrophy.

This question is further considered in the results of my bacteriologic studies (which will soon be published) of gastritis chronica produced artificially in dogs by first treating the mucous membrane with tannic acid and other irritants, then infecting it with material derived from the mucous walls of the stomach of patients suffering from gastritis glandular in the various stages. In cases of simple dilatation and cases of stagnation, when carcinoma was absent, lactic acid bacilli could also be found but were not the predominating germs. In these cases, socius ventriculi and other yeast germs appeared more numerous in the cultures.

Between carcinoma of the stomach and simple gastritis there is this difference: In carcinoma, the carcinoma alone may be sufficient to produce poison or other products which render the mucous membrane a fertile soil and permit germs to develop on the walls. In gastritis, the predisposing cause may not be so constant and so powerful as carcinoma, but errors of diet and diseases of other organs also render the stomach a fertile soil for the constant colonization of microorganisms that produce the inflammatory process of a chronic nature. In the cultures, the lactic acid producing bacilli are present in most cases, and frequently almost pure cultures appeared in making the ordinary bacteriologic preparations.

The method of growing germs in the gastric juice mixed with the mucous and food remnant answers well in some cases. In growing the germs upon the mucous membrane of the stomach of pigs, previously sterilized (by fractional sterilization at 50 to 55 cc.) it was found an advantage to sponge the surface of the membrane with sterilized starch water. Many of the lactic acid bacilli formed colonies more rapidly, and adding starch to a tube culture seemed to increase the formation of lactic acid.

There are a large variety of germs capable of producing lactic acid, depending upon the soil and other conditions of heat and moisture. All varieties of lactic acid bacilli do not form gas; in fact, the lactic acid bacilli derived from cases of carcinoma of the stomach did not produce gas to a great extent in tube cultures. The following cases are selected from a large number for comparison. In these cases analyses were made for the presence of lactic acid by the Boas method, carried out with strict precautions; also tests were made with Uffelmann's magnet. The bacteriologic

NOTE.—Since this work has been completed it has appeared in the *Wiener Medical Wochenschrift*, Nos. 1 and 2, 1895. *Eine neue Methode der Diagnose und Therapie gewisser Magenkrankheiten und bakteriologische Studien bei denselben.*

An error occurred in this article, in stating that I use the stomach of birds. It should read, the stomach of dogs and pigs.

investigation consisted in cultures upon various nutrient media and we noted in each case the presence of lactic acid of fermentation; according to Boas' method by introducing oatmeal soup at night, the stomach previously cleaned with sterilized water and the contents removed next morning, filtered and analyzed quantitatively. It was found in many cases that the mucous membrane and motor functions showed marked changes. In carcinoma of the stomach it was often markedly increased, and the bacteriologic investigation seemed conclusive, that a large colonization of lactic acid bacilli occurs.

In carcinoma it often occurs that there is no stenosis—no retention of food—especially early in the disease, and after a test meal given according to Boas' method but little of the stomach juice can be procured, and hence little, if any, lactic acid demonstrated. In using the gyromele and removal of adherent mucous from wall, cultures were found which proved to be the lactic acid bacteria. Upon this and other suspicious evidence an exploratory laparotomy was advised.

Mrs. Jennie L., age 51; German, appeared at the Post-Graduate clinic Nov. 6, 1893, complaining of a diffuse pain in the epigastrium, radiating to the xiphoid appendix, vertical headache, anorexia, constipation. Family history negative. No symptoms up to two years before, when there appeared a slight uneasiness after eating; gradual anorexia; symptoms gradually increased. Emaciation and pallor followed occasional nausea, until her condition presented marked and rapid degenerative changes. She was under constant medical care. Her case was finally diagnosed as a probable carcinoma of the stomach, and referred to my clinic. Examination revealed anemia; cachectic appearance of skin; absence of panniculus adiposus; hair dry and brittle; absence of all but three decayed molars; gingivitis universal; chest organs with liver slightly enlarged. Abdomen retracted, palpation of the prolapsed pylorus slightly enlarged; no palpitation. Coloptosis and dilated sigmoid; rectum large hemorrhoids; genito-urinary organs negative; blood 3,200,000 corpuscles, hemoglobin 45 per cent. No albumen or sugar in urine; indican with aromatic sulphates increased.

Clinical examination of stomach contents, Ewald's test made; withdrew 50 cc., reddish yellow color, pungent odor. Litmus +, HCl +. Total acidity 40; Uffelmann's for lactic acid after extracting with Squibbs' ether ++, Rennet action delayed, pepton +.

Bacteriologic examination, empty stomach, material removed from the walls with the revolving sponge, four slides, crowded with colonies—bacilli long and short, macro- and micrococci.

Cultures. On the mucous membrane of the stomach of pigs by stroke cultures ten varieties, six produced lactic acid in bouillon made from the mucous membrane of the stomach of the pig, with sterilized starch water added. Along the line of the needle, especially the second line, most of the colonies proved to be lactic acid forming bacilli.

Aug. 20, 1894, had not seen the patient for six months. She was under treatment by assistants. Physical examination showed evidence of carcinoma. Analysis of stomach contents after Boas' method. But a small quantity of stomach contents could be procured; stomach contents washed out, wash water examined, found lactic acid bacilli in colonies.

Nov. 10, 1894, patient appeared much emaciated; cachectic, operation refused.

Dec. 5, 1893. J. J. O'C., age 44, fireman; referred to clinic as a case of carcinoma of the pylorus; complains of slight pain in the epigastrium—a distressed feeling after eating—anorexia, constipation. Family history negative. Previous history negative up to three years ago, began to have digestive disturbances. Lost thirty-five pounds in weight; was disturbed with acid eructations for four or five hours after meals. Great mental depression. Physical examination, rhinopharyngitis, hypertrophic mouth; caries of teeth; gingivitis; tongue coated and depressions of teeth; chest organs negative; liver and splenic area normal; abdomen retracted. Palpation revealed slight thickening of the pyloric region which by the aid of revolving sponge in stomach proved to

be the pylorus. With the revolving sound in the stomach, the great curvature palpated two seconds below umbilicus: transverse colon prolapsed; rectum negative; genito-urinary organs, slight prostatic hypertrophy, otherwise negative.

December 8, blood counts 3,940,000; hemoglobin 55. Urine, no sugar or albumen; indican in excess; stomach contents, test meal Ewald's, light watery fluid, 50 c.c. filtered HCl+ (Uffelmann's). Extracted with ether, lactic acid reaction. Dec. 14, 1893, bacteriologic slides show a large number of colonizing rods and micrococci. December 21, no lactic acid forming colonies appeared.

Diagnosis, after complete examination of history, physical, chemic and bacteriologic investigation. Gastritis glandularis with hypertrophy of pylorus, drainage and dilatation of stomach. Treatment carried out. September, 1894, patient showed a probable compensatory hypertrophy of the dilated stomach, for it emptied itself perfectly within five hours. All symptoms disappeared and gain of twenty-five pounds.

History and examination by the house physicians, Drs. Walker and McGrew. The following is a short extract: A. M. C. entered Cook County Hospital July 2, 1894, age 45; married. Complained of pain in abdomen. Mother died of consumption; had digestive disturbances all her life. Present illness began six months ago and within last three months noticed tumor in abdomen. Emaciating for last three months. Examination. Abdomen hard mass palpated horizontally with umbilical line, smooth surface, extending to median line; on upper and outer corner of left side of tumor was felt a detached nodule about the size of a dollar, did not move on respiration. Appeared in my hospital clinic August 2, 1894, after Ewald's test meal. Litmus +, no HCl, total acidity 21; Uffelmann's + (extract ether). August 3, removed material from the walls with the revolving sponge (gyromele) for cultures. At the same time could palpate the sound in the stomach, showing the tumor to be connected with the anterior wall of the stomach, extending below the umbilicus. August 4, stomach contents for lactic acid after Boas' method, which gave positive results, but no complete quantitative estimation was made further than the iodoform emulsion. The bacteriologic examination showed few colonies of the lactic acid forming bacilli. Positive diagnosis could not be made. Carcinoma of the anterior wall was considered. Patient died August 9, 1894.

Extract from morgue record posted August 11, 1894: Stomach low down in peritoneal cavity; gastropnoia, white raised nodular areas; adherent with omentum and transverse colon. Anterior wall of the stomach thickened and adherent to abdominal wall, forming a thickened mass; the peritoneum studded with miliary tubercles.

Diagnosis: 1, tuberculosis of peritoneum; 2, surgical kidney; 3, ascites; 4, perisplenitis.

E. R. LECOUNT, M.D.

J. W. WALKER, M.D.

H. W. RICHTER, M.D.

Maggie L., admitted to Cook County Hospital, July 29, 1894. Complained of pain in epigastric region and vomiting; family history negative; suffered for five months with heavy feeling in region of stomach, until acute pain with vomiting ensued. Physical examination, patient considerably emaciated; did weigh 136 pounds, reduced to 100 pounds. Chest organs negative; abdomen retracted; half way between the xiphoid and umbilicus was heard a peculiar blowing sound—a bruit—no palpable tumor. July 3, examination of the stomach contents after Ewald's test meal; HCl—; Uffelmann's reagent after extracting with ether—+; only the stomach tube was passed, but from the mucus present cultures were made and lactic acid demonstrated in the culture media. August 2, 1894. Boas' test meal; lactic acid .15 per cent; patient died August 3, 1894.

Extract from post-mortem record: August 6, 1894. Stomach contained 635 grams dark clotted blood; on posterior wall of the stomach was a large irregular fungating mass, reaching from the greater to the lesser curvature, not involving the cardiac or pyloric end. This involved the tail of the pancreas which was bound closely to the stomach wall. Pancreas only a portion normal tissue; the tail made up entirely of a grayish mass which was adherent to the posterior wall and a part of the tumor mass.

Diagnosis: 1, carcinoma of the stomach and pancreas;

2, retroperitoneal glandular involvement; 3, compression of the abdominal aorta.

# ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 272.)

## CHAPTER VI.

### RELATIONS OF YELLOW FEVER TO SUNSTROKE.

The severer grades of yellow fever, attended with high temperature, reaching 108 degrees F., and over, and running a rapid course in two or three days to a fatal termination, present some symptoms in common with those cases of sunstroke in which the muscular and nervous prostration is accompanied with rapid and decided elevation of temperature. In cases of sunstroke, which occurred during the month of July, 1873, the temperature reached from 110 to 112 degrees F. in the axilla, at the time of death, and probably reached 115 degrees F. in the heart and internal organs. Similar elevations of temperature in sunstroke have been recorded by Dr. Bennet Dowler and others.

The phenomena of sunstroke appear to be dependent mainly upon the complex and unstable chemic constitution of the blood, and the dependence of the development of the physico-vital phenomena of the nervous and muscular forces, upon a definite degree of temperature. In common with other complex and highly elaborated organic fluids, which are continuously supplied with oxygen, the definite physical and chemical constitution of the blood can be maintained only within certain degrees of temperature. Unless a definite physical and chemical constitution of the blood be maintained, the necessary nutritive elements will not be supplied to the organs and tissues, and alterations in the secretions, and aberration of the muscular and nervous forces are inevitable. When the temperature of the blood rises above a certain point it is probable that a new series of chemic actions are developed; and compounds are generated which act as poisons to the nervous system. The rise of the temperature in the blood must also be attended with disturbances in the normal electric currents of the nerves and muscles. The great increase in the amount of carbonic acid, and the corresponding rapid consumption of oxygen in the blood must also be considered as important factors in the production of that state known as sunstroke. It is probable also, that as in certain cases of yellow fever, the center of the cerebro-spinal system which regulates animal temperature, as well as the vasomotor centers are involved. The derangement of these nervous centers is probably secondary to the chemical and physical alterations of the blood. It appears also, that the sudden failure of the heart, when the temperature of the blood rises above 110 degrees F., is due to the physical and chemical alteration and coagulation of the contractile constituents of the muscular fiber of the heart.

The remarkable phenomena of "sunstroke," "heat stroke" or "thermic fever," are most generally manifested in individuals working in intensely hot weather in ill ventilated apartments and cellars, in rooms artificially heated as in laundries, bar-rooms, wine cellars, and densely crowded tenement houses; in those addicted to the intemperate use of ardent spirits, in whom the capillaries of the brain are dilated and degenerated and the constitution of the blood deranged by the impairment of the functions of certain organs, as the liver and kidneys; and in teething children, exhausted by diarrheal discharges, and by the deranged reflex nervous actions, excited by the continuous irritation of the gums and dental nerves.

The foul air, loaded with the exhalations from the skin and lungs, and with carbonic acid, of the crowded houses of the poor, in narrow filthy streets, without doubt depresses the nervous and muscular forces, and prevents the proper maintenance of a definite temperature, by a free transpiration from the cutaneous and pulmonary surfaces.

The phenomena of sunstroke furnish conclusive evidence that mere elevation of temperature, apart from the action of any distinct febrile poison, may be the source of important changes in the blood, and fatal depression in the muscular and nervous systems. The phenomena of yellow fever and of other febrile diseases are rendered more complicated by reason of the disturbing agencies of the heat developed, and it is important that a thorough analysis of the blood, excretions and secretions in sunstroke be made, as forming a basis for the correct appreciation of the mere effects of temperature upon the blood and upon the nervous and muscular systems in yellow fever, independent altogether of the direct action of the febrile poison. Unfortunately, medical science is as yet without the necessary data for the institution of such an inquiry.

### RESPIRATION IN YELLOW FEVER.

In many cases of yellow fever, the respiration is accelerated to a comparatively small extent; in cases of great severity, however, the respiration may be greatly increased in frequency, while the pulse may be even below the normal standard, and far below what is usual in other diseases with a similar elevation of temperature. The following cases present striking illustrations of the want of correspondence between the respiration, pulse and temperature in severe and fatal cases of yellow fever:

*Case 1.*—Yellow fever, black vomit, urinary suppression and death. G. H., age 33, laborer; native of Germany. Came on steamboat from St. Louis and had been in New Orleans one week before he was attacked. Entered hospital Oct. 11, 1873, at 4 P.M. Was vomiting black vomit when he entered. Sick five days before he entered the hospital, and in a state of nervous and muscular prostration and great capillary congestion. Black vomit abundant; gulps it up apparently without effort and squirts it on the wall and over the bed clothes. At 6 P.M. pulse 81, respiration 48, temperature of axilla 102.8. Complete suppression of urine, pain in epigastrium, delirious. Died next morning at 6 o'clock, fourteen hours after entering the hospital.

*Case 2.*—Yellow fever, jaundice, suppression of urine, black vomit, slow pulse, rapid respiration, death. J. A. H., age 30, native of United States, actor. Came down the Mississippi River on steamboat from St. Louis two weeks before his attack of yellow fever. Entered Charity Hospital Oct. 15, 1873, 5 P.M. Comatose; entire surface of a deep golden color; great congestion of peripheral blood vessels and capillaries; face of a purplish mottled hue; conjunctiva yellow and congested; pupils greatly dilated and incapable of responding to the stimulus of light; pulse small and

thready. Threw up black vomit in the wagon before entering the hospital; mustache and side of face smeared with black vomit. Oct. 16, 1873, 8 A.M., pulse 110; respiration 22; temperature of axilla, 102 degrees. 8 P.M., pulse 68; respiration 68; temperature 105.5 degrees F. Has passed no urine since entrance into the hospital. With the catheter, I drew off about one fluid drachm of yellow urine, loaded with albumen, bile and granular casts of tubuli uriniferi and excretory cells of kidney. Upon standing, the urine let fall a heavy deposit of urates. The patient died three hours after this observation, at 11 P.M.

It is worthy of note that in this case with a temperature of 105.5 degrees and respiration 68 to the minute, the pulse was only 68 beats to the minute.

I have observed a similar condition, viz., the pulse and respiration of equal rapidity in no case of acute disease; and in fact while the pulse may be greatly reduced in frequency when jaundice supervenes in malarial fever and in pneumonia, and while in many diseases there is no absolute correspondence between the temperature and rapidity of the heart's action within narrow limits; at the same time yellow fever is distinguished from other acute diseases by the frequency with which the pulse diminishes in rapidity after the establishment of the febrile excitement. This proposition will be established by a comparison of the pulse, respiration and temperature in various diseases with the observations already recorded with reference to yellow fever.

In addition to the large number of cases of various diseases, recorded in the first volume of my "Medical and Surgical Memoirs," the following cases are presented for immediate comparison and definite conclusions:

*Case 1.*—Erysipelas of head and face engrafted on malarial fever. Patrick O'Hern; native of Ireland; weight 160 pounds; height five feet eight inches; has been in the United States three years; admitted into Charity Hospital, Nov. 22, 1876, with intermittent fever, contracted several months before, in the swamps of Arkansas. The intermittent fever was arrested by the usual remedies. On December 8, the patient was seized with a chill followed by high fever, which continued without remission and on the 9th erysipelatous inflammation of the face appeared. The features became rapidly swollen and the inflammation which began on the left cheek rapidly invaded the integuments of the face and head. The bowels were freely opened by a mercurial purgative and quinin administered.

On the 12th, the patient was placed upon the following:

R Quinia sulph . . . . . 3i  
 Potassa chloratis . . . . . 3ij  
 Acidi hydrochlorici dil. . . . . 3iij  
 Zinc ferri murates . . . . . 3iv  
 Aquæ menth. pip. . . . . f.3iij  
 Mix.

Sig.: 30 drops in a wineglassful of water every four hours.

The local treatment consisted in painting the skin of the face and head, in advance of the line of inflammation

with tincture of iodine. These measures finally arrested the progress of the inflammation and on December 20 the temperature of the axilla had fallen to 99 degrees F. The following table presents the relations of the pulse, respiration and temperature:

The recovery of this patient was satisfactory and complete and he was discharged in good health, capable of performing manual labor.

*Case 2.*—Erysipelas of face and head. John Toole; laborer; age 50 years; weight 180 pounds; height five feet ten inches; dark hair, dark eyes, dark complexion; admitted to Charity Hospital Dec. 23, 1876. Integuments of face bright red and greatly swollen. The swelling is so great as to completely close the eyes and to obliterate the features. Previous to coming to New Orleans had worked on the levees, near Donaldsonville. Has a scar on the left side of the head caused by a blow about three weeks before. This injury appeared to be the exciting cause of the erysipelatous inflammation. The treatment of this case was similar to that instituted in the preceding case, and with like favorable results. The inflammation gradually subsided and after the complete restoration of health the patient was discharged. The following is the record of the pulse, respiration and temperature:

*Case 3.*—Rubeola, dark purple eruption, high temperature, death. John Chilton; native of New Orleans; age 17; laborer; height five feet; weight 100 pounds; dark brown hair, gray eyes, dark complexion, sharp features; entered Charity Hospital Dec. 20, 1876. Patient states that he had been seized on the morning of the 9th inst. with a severe rigor, followed by intense fever, accompanied by pain in the head and back. December 11, 8 A.M., I saw the patient for the first time; face and surface generally greatly congested, presenting a purplish mottled appearance. Pulse 155; respiration 40; temperature of axilla 105 degrees F. Left lung congested; dull upon percussion, with physical signs of pleuro-pneumonia. Painful cough and respiration. Evening, rash over entire surface of a deeper color and of more distinct appearance; left lung and lower lobe of right lung congested. Pain, cough and jerking labored respiration. 8 P.M., pulse 156; respiration 47; temperature 106 degrees. Alcoholic stimulants, quinin and nutritious diet were ordered, but appeared to produce no beneficial results; neither was the local application of turpentine in the form of stupes attended with any diminution in the severity of the pulmonary symptoms.

December 12, A.M., pulse 142, respiration 39, temperature 104.5 degrees F.; December 12, P.M., pulse 129, respiration 42, temperature 105 degrees F.; December 13, A.M., pulse 124; respiration 35; temperature 104.5 degrees F.; December 13, P.M., pulse 136, respiration 36, temperature 105 degrees F.; December 14, A.M., pulse 144, respiration 36, temperature 104.5 degrees F.

On the morning of December 14, the patient presented a livid appearance; great difficulty in breathing, dark blotches on his body running together, but more defined on arms; legs and feet. Tongue, which had been heavily coated, peeling off, leaving a raw surface. Intense thirst, feeble fluttering pulse. Died at 10 P.M.

*Case 4.*—Intermittent fever, congestion of right lung. K. Orbison; age 26 years; height five feet eight inches; light hair and blue eyes; native of Chicago. During the past summer was exposed to malaria in Mississippi and entered the Vicksburg hospital with chills and fever. Entered Charity Hospital on December 27, with high fever, furred tongue and congestion of lower lobe of right lung. The internal administration of quinin and Dover's powder (2 grains of each every three hours) and of the tincture of yellow jessamine (10 drops every three hours) and the local application of turpentine over affected lung, were attended by the resolution and disappearance of the pulmonary congestion. On January 5, the patient suffered with another paroxysm of fever which yielded readily to quinin. The following observations were recorded:

December 27, pulse 120, respiration 30, temperature 104

degrees F.; December 28, pulse 112, respiration 28, temperature 98 degrees F.; December 29, pulse 94, respiration 28, temperature 100 degrees F.; December 30, pulse 78, respiration 27, temperature 99 degrees F.; December 31, pulse 80, respiration 24, temperature 98 degrees F.; January 1, 1877, pulse 72, respiration 22, temperature 98 degrees F.; January 2, pulse 70, respiration 24, temperature 98; January 3, pulse 90, respiration 30, temperature 99 degrees F.; January 4, pulse 72, respiration 24, temperature 99 degrees F.; January 5, pulse 130, respiration 28, temperature 105.5 F.

*Case 5.*—Chronic malarial poisoning, general anasarca, ascites. Edwin Toll; age 39; admitted to Charity Hospital March 3, 1877. Native of Philadelphia; mechanic. Has been in Louisiana twelve months and has been living in the swamps of Quehito Parish. With the exception of syphilis twelve years ago, has enjoyed good health, up to August 1, 1876, when he was attacked with chills and fever, "swamp fever." The chills have continued at intervals up to present time. Pale, anemic, with greenish-yellow tinge of surface. Spleen enlarged and painful upon pressure. Abdomen distended with liquid. Extremities, especially the legs and thighs greatly swollen and pitting deeply upon pressure. Urine high colored, moderately abundant, but free from albumen. It is probable that the liver has been deranged by the action of malaria, as well as by alcoholic stimulants, which he is said to have used in excess. Much benefit was derived from the following combination:

℞ Quinia sulph. . . . . ℥i  
Pulv. digitalis. . . . .  
Pulv. scilla. . . . . āā grs. v  
Extract rhei. . . . .  
Extract aloes . . . . .  
Extract colocynth comp. . . . .  
Gamboge . . . . . āā grs. x  
Mix.

Divide into ten pills; one pill every six hours.

The action of the kidneys was promoted by cream of tartar in drachm doses, three times a day. After the bowels were freely moved by the preceding measures, the tincture of bark and quassia, together with quinin and iron were freely used and with marked benefit. Under these measures the dropsical effusion disappeared and the complexion assumed a healthy appearance. The following observations were recorded:

*Case 6.*—Acute mania; general paralysis of lower extremities. Patrick J. Fitzpatrick; age 40; native of Ireland. Has resided in New Orleans thirty years. Admitted to Charity Hospital, Feb. 20, 1877. Can give no coherent account of himself. Laughs, cries, screams, crows like a cock, preaches and talks wildly and incoherently. Religion and military affairs appear to occupy his mind chiefly. Ofttimes repeats the prescriptions, as I give them to the student, passing from bed to bed; hearing appears to be very acute. Does not rest at night; can not stand on feet but falls forward. Blisters to back of neck and bromid of potassium and hydrate of chloral, as well as minute attention to the condition of the bowels appeared to afford some relief and to moderate the ravings to some extent. The case, however, appeared to be but little improved when I gave up the case on March 15.

The following observations were recorded: March 8, pulse 100, respiration 24, temperature 99 degrees; March 9, pulse 100, respiration 25, temperature 99 degrees; March 10, pulse 98, respiration 24, temperature 99 degrees; March 11, pulse 80, respiration 24, temperature 99 degrees; March 12, pulse 85, temperature 98.2 degrees; March 13, pulse 85, respiration 24, temperature 98.2; March 14, pulse 88, respiration 24, temperature 99 degrees.

*Case 7.*—Double pneumonia supervening in malarial fever. James Rooney; native of Ireland; age 30 years; light complexion; weight in health 165 pounds; height five feet eight inches. Stone cutter by trade; has been in America four years, but has not worked at his trade during this time. In

November, 1876, he obtained work on the Jackson railroad, and labored in mud and water up to his knees. Two weeks after beginning work in the swamps, was seized with chills and fever, and returned to New Orleans. Was sick one week before entering the hospital and during this period had little or no attention. Admitted to Charity Hospital, Jan. 24, 1877. I saw him for the first time on the 25th; found upon examination that the entire right lung and the lower portion of the left lung were completely solidified. All respiratory sounds with the exception of the tubular breathing were absent from the right lung. Expectoration very scant; respiration hurried; great congestion of face, with purple lips and tongue; rapid pulse and high temperature; absence of chlorids from the urine.

Notwithstanding the unfavorable and almost hopeless aspects of this case, the persistent use of quinin, Dover's powder, and alcoholic stimulants, carbonate of ammonia and nutritious diets and the local application of turpentine, were attended with marked improvement of the symptoms. The chlorids returned to the urine, the left lung was restored and portions of the right lung manifested crepitant, subcrepitant and mucous râles. A large cavity found in the superior and middle lobes of the right lung. During the breaking down of the lung tissue, the patient suffered from hectic fever, profuse sweats and great exhaustion. Convalescence although slow was finally and completely established.

The following observations will illustrate the relations of the pulse, respiration and temperature in this grave case:

(To be continued.)

# NERVOUS DISEASE IN EARLY SYPHILIS.

Read before the Chicago Academy of Medicine, October, 1894.

BY G. FRANK LYDSTON, M.D.

Professor of the Surgical Diseases of the Genito-Urinary Organs and Syphilology in Chicago College of Physicians and Surgeons; Surgeon in charge of the Masonic Hospital of Chicago; Fellow of the Chicago Academy of Medicine; Lecturer on Criminal Anthropology in the Kent Law School; Fellow of the American Academy of Social and Political Science, etc.

(Concluded from page 276.)

Wille, several years ago, made an exceedingly valuable analysis of the psychoses due to syphilis, which he found were divisible into the following classes: 1, irritative psychoses based on cerebral anemia following syphilitic infection even from its very beginning; 2, simple inflammatory psychoses due to meningitis and cerebral softening; 3, neoplastic psychoses proceeding from cerebral meningeal gummata. Griesinger states that when acute mental disease affects patients during the secondary stage of syph-

ilis, it will be chiefly those whose brain is organically affected, who have previously presented symptoms of abnormal cerebral activity or who come from neurotic families.

Wille says that mental symptoms may appear two months, or even two weeks after infection, certainly with the onset of the secondary symptoms. Hildebrand has had very similar experience.

Leubuscher was the first to establish the existence of mental symptoms during the secondary period. Prior to his article these had been regarded as tertiary accidents.

Berthier, some twenty-seven years ago reported several acute cases of insanity occurring during the secondary period. Fournier has described several cases of insanity, due to secondary syphilis, varying in type from confusional insanity to cataleptoid states.

Mickle has observed several cases of insanity due to secondary syphilis in which the psychic effect of syphilis was similar to that of alcohol. Clouston substantially agrees with Wille. He says the psychoses occur in the secondary stage of the disease, coincidentally with the eruption, and are curable and rare.

Cadell reports a case characterized by mental excitement and restlessness which reached its height seven months after the initial lesion, and five months after the appearance of the secondary symptoms, with the onset of which the mental symptoms began. This case consisted of a confusional delirium. The patient slept but little, but rode recklessly about at night. A year later melancholia has set in, accompanied with paralysis of energy, so that the patient scarcely left his bed. He at length made a good recovery.

Savage states that constitutional syphilis acts by causing gummata, by producing arterial disease, by producing local degenerations, or by causing a cachetic state. Regis states that the psychoses of secondary syphilis occur on the appearance of secondary accidents accompanied with fever, principally at the time of the eruption. The onset is more or less brusque, and takes the form of acute or subacute mania or melancholia, preferably mania; it is sometimes of a circular type. It is usually of short duration, disappears with the febrile manifestations to which it is due and readily yields to mercurial inunction.

Luys, admitting that mania, melancholia, and hallucinatory confusion can occur, asserts that these are but the epiphenomena of a morbid process in evolution.

Kiernan's own cases are of great interest:

*Case 1*, was that of a 35-year-old Canadian, a periodically drinking tailor, of criminal antecedents and parentage. A sister and aunt are prostitutes. One brother is idiotic and one a professional burglar. Four weeks before admission he had contracted the initial lesion, which healed up without any treatment. Two weeks before coming under care he was very morose and irritable, felt chilly sensations all over the body, and was very languid. Six days before coming under care he was attacked by a very intense fever, and on the following day complained of insects crawling beneath his flesh, and of men being at the window with guns to shoot him. He was markedly terrified. When he came under observation he had a temperature of 104.9. He was markedly agitated, constantly in motion, and had an expression of extreme terror. He was ordered:

R Ex. conii. . . . . fl  
Ex. hyoscyami . . . . . fl  
Chloral hydratis . . . . . aa.2.00

M.S. At a dose, in water thrice daily.

Quinin was given in 10 grain doses thrice daily, but neither this or the sedative had any effect on the mental symptoms of the fever. On the third day the history already narrated was obtained, whereupon the attendant was ordered to rub 30 grains of mercurial ointment into the armpits and clefts of the thighs. During the following night the patient slept with relative comfort; his temperature fell to 98.3. He was less agitated, but retained his delusions, and was very little inclined to remain alone. This treatment continued two days, the temperature and mental state remaining the same. The third day after this a roseolaceous eruption appeared on the forehead and neck. This was at first a simple roseola, but in twenty-four hours became pustular and gradually melted down into dark brown crusts, flattened and depressed which, when removed, showed a grayish film bathed in pus underneath. The attendant, soon after the appearance of the last, neglected to rub in the mercurial ointment, whereupon the patient's temperature rose to 103.6, and he became violently excited, rushing wildly from one room to another, saying that he was about to be shot, and that spiders were eating his brain. His countenance expressed terror and he was always in motion. As a means of restraint to secure treatment, a sheet was smeared in mercurial ointment, the patient was wrapped in this and then confined in a camisole. The next day his temperature fell to 101.7. Although still retaining his delusions he was much more at ease and less agitated than he had been since his admission. Treatment was continued three weeks. The mental disturbance became less and less marked. The eruption began to cicatrize, and finally healed up in places, leaving thin red lines radiating from the center. The delusions grew less and less vivid until they seemed to the patient but dreams of an unpleasant nature through which he had passed. He retained some gruffness and irascibility, but this was evidently natural to him and not insanity of manner. He made a good recovery and remained in good health.

*Case 2*.—A baker, 25 years old, a moderate drinker, had a brother who died insane, and a sister under treatment in an insane hospital. When he came under observation he was very much agitated and had well marked auditory and visual hallucinations. He saw spiders crawling over him, and guns protruded from holes in the wall to shoot him. He heard wolves and lions howling and roaring at him. He kept always in motion, but by dint of great effort could control himself and give a few relatively rational answers to questions. After recovery he gave the following history: Four weeks before coming under treatment he had contracted a chancre. About the beginning of the fourth week after this he had a distinct chill followed by a high fever. Believing this to be the onset of malaria, but feeling unaccountably depressed, he took 10 grains of quinin and visited Central Park. While there he was so frightened at the howling of the wolves that his companion was obliged to draw him away to avoid attracting attention. This scene was repeated before the lion's cage. He was not afraid of the animals, but of their howling. On his return home he became exceedingly delirious and cried out about wolves and lions. In two days hospital treatment became necessary. On admission he had a temperature of 104 degrees. He was fairly nourished. He was rather loquacious, which loquacity was at times broken in upon by his hallucinations. He was ordered the same treatment as in the previous case, which was without effect. The fourth day of treatment a roseolaceous eruption made its appearance on his forehead around the roots of his hair. The patient was ordered a mercurial ointment applied as in the other case. In twenty-four hours his temperature fell to 99.8 degrees. He was much quieter, but retained his delusions and hallucinations. The next day a similar eruption to that described appeared on the arms and trunk, which gradually formed flat pustules. These became covered with greenish-brown crusts, which when removed, showed a grayish-red ulceration beneath, and were surrounded by a copper-colored areola. The delusions and hallucinations grew less vivid for the next two weeks. By the time of the total disappearance of the eruption (at the beginning of third week) they disappeared also, leaving the patient in a dazed condition. He remained relatively stationary for about two weeks, when he gradually brightened up, and recovered, four months after admission.

*Case 3*.—An Irish American, 32 years old, came under my care with a decided corona veneris and temperature of 103½ degrees. He was in a state of hallucinatory confusion similar to those cases already described and he was wrapped up in a mercurial ointment sheet. The eruption pursued the usual course. With its gradual fading the vividness of the patient's

hallucinations—which chiefly related to locomotives behind him—grew fainter, and his motor agitation grew less. Two months later he had passed into a cataleptoid state; from this he emerged into a state of maniacal exultation with a verberation resembling that of katatonia. This passed into a state of depression lasting a month. From this the patient recovered and has since remained well.

Kiernan comments upon these cases as follows:

"These cases resemble those of Cadell and Mickle. Their symptoms do not agree with those found by Leubuscher, Albers, Englested, and Gros, in that in none was to be found any evidences of hypochondria or of syphilophobia, but certainly these are present in other psychoses and may be produced, as Leidesdorf and Savage have shown, by moral causes alone in luetic cases. I do not believe that these cases should have a place otherwise than with the confusional insanities, and this view is also held by Regis. They are simply the result of a systemic exhaustion which, as I have elsewhere shown, is produced by many causes."

To the mind of the author of the present paper, the toxin view of such cases is the most logical one. An instability of cerebral structure and function, moral and mental influences, alcohol and previous cerebral irritation from any cause whatever, may act as the factors which determine the toxic process to the brain, but the intoxication of the brain by syphilitic toxins, is probably the essential factor.

My friend Dr. Norbury, late of the Central Hospital for the Insane at Jacksonville, Ill., has reported two cases occurring during secondary syphilis, one of which was associated with a primary sore which had not yet disappeared. As both cases are complementary to the series which I have to report I take the liberty of presenting them in full:

*Case 1.*—A man, aged 21 years, who contracted syphilis three months previously. A phagedenic ulcer had formed, and was not quite healed when first examined. There was general enlargement of the gland, mucous patches in the mouth, and a pustular inflammation of the forehead. He was then under treatment for syphilis, and had been for some time, so that the manifestations of the disease were modified by the mercury he was taking. The cerebral symptoms were, briefly: insomnia, headache, followed by somnolence, and later by a somnambulistic state. The last condition was first noticed while attending a party. He had a severe attack of headache, with vertigo, asked permission to lie down, was shown a bedroom, and his recollection ends with his lying upon the bed. He reappeared in the dining room after a short absence, and much to the astonishment of all, was quite devoted to a young lady with whom it was known he had previously quarreled. She could not account for his devotion, excepting by the belief that he had been drinking. His friends, fearing that such was the case, invited him to remain all night. In the morning, when told of his reappearance on the floor, and his attention to the young lady, he denied all recollection of it whatever, and accused his friends of joking. He further denied taking liquor of any kind.

Ten days later a similar attack, with the same prodromes occurred. On this occasion he left home, and when he regained consciousness found himself in a hotel in a city forty miles distant. How he came there, how long he had been away from home, or what he had been doing he knew not. He returned home, and in a few days later renewed the trip. This time it was forty-eight hours before he regained consciousness. As before, he had no recollection of what had occurred. A third time he started for the neighboring city, but was overtaken by his brother at the railroad station. When accosted by his brother he appeared natural in his behavior, but was not subject to external influences, was seemingly in deep thought, was more or less automatic in his movements, and would not converse. When he regained consciousness he was greatly surprised to learn what he had done.

When Dr. Norbury saw him on the next day, he was worried, melancholic, and self-accusative. After satisfying him-

self that it was undoubtedly a case of syphilis, the Doctor put him upon the iodid of potassium, and also directed him to continue the mercury. About three weeks later he reported again, saying that he had not been troubled since he first saw me, excepting with headache, lasting for a short time. He stated that he contemplated going to Hot Springs, Ark., and this was the last time the doctor saw him. It has since transpired that he returned home in due time, very much benefited, and is now in a normal mental condition.

Dr. Norbury's remarks upon this case are of interest. It is worthy of comment that he entertains essentially the same views as myself regarding the possible importance of vasomotor disturbance in early cerebral syphilis.

"The strangeness of the symptoms, the departure from the ordinary type of organic disease, and the somnambulistic manifestations, all point to some perversion of the circulation, or an abnormal condition of the blood itself, affecting the supreme cerebral centers. If the cause was perverted circulation, we do not know the actual condition of the brain under these circumstances. It is reasonable to conjecture that alteration in the cerebral circulation was the cause, when we consider the distribution of the arteries and the physiology of sleep.

"The arteries which supply certain areas of the convolutions may be affected, causing activity of the circulation in these vascular areas, and as a result, somnambulistic dreams. The affection of the arteries may be either vasomotor disturbance, or cell proliferation within the walls of the vessel of the pia, causing diminution of the circulation, and consequently, malnutrition and lessening, or perversion of the functional activity of the ganglionic cells in the underlying brain substance. If such is the case, the observation of, and comparison with, other cases might lead to localization of the mental faculties."

*Case 2.*—Late secondary phenomena. A man, aged 23 years, single (history defective.) For six months prior to his admission to the Illinois Central Hospital for the Insane he was confined to his bed at home. When admitted he was feeble and emaciated, his circulation was poor, and bowels constipated. The mental symptoms were those of acute primary dementia. He had not spoken for several months, stared vacantly, and apparently was not conscious of his surroundings. He was filthy in his habits, had an inordinate appetite, and would eat anything, including his own feces. No history of syphilis was given by his friends, but evidences of primary lesions were marked. Secondary manifestations, such as thinning of the hair of the scalp and skin eruptions, resembling psoriasis on the posterior surfaces of the lower extremities and on the anterior surface of his arms were present. No marked superficial symptoms were shown.

Acting on the supposition that the case was one of syphilis, I immediately put him on anti-syphilitic treatment. No marked change occurred for several weeks, except a gradual improvement in his general health. At the end of three months he had improved so much that he was able to dress himself and attend to his wants, and was interested in his surroundings. Ataxic aphasia soon took the place of the complete aphasia which had prevailed for six months. This gradually faded away with the improvement in his general mental condition, and he was able to converse rationally, his articulation becoming perfect. He then gave me a history of syphilis contracted two years before. The primary lesions were slight, and he had no recollection regarding the appearance of the secondary phenomena. He was discharged cured, so far as his insanity was concerned, six months after admission. He has gained forty-five pounds in weight, and has all the indications of good health. He is now married, and follows his trade, that of a painter and decorator in Chicago. One and one-half years have elapsed since he was discharged, and yet he has had no evidence of a return of the disease.

Regarding this case Dr. Norbury says: "The case is interesting because of the long duration of functional disorder of the brain, and the subsequent com-

plete recovery, with no evidence whatever of organic change. The pathology of the case can probably be explained by conditions similar in nature to those in the preceding case, namely, an arteritis not sufficient to produce organic changes, but so far advanced as to affect the nutrition of that part of the brain presiding over the intellectual faculties. The co-existing aphasia locates the disturbance in the vicinity of the Sylvian artery, for we all know that impairment of speech is due to the involvement of the terminal branches of that artery."

Although the date of the appearance of brain symptoms in Dr. Norbury's second case was two years after the chancre, it still must be classed as an early lesion of syphilis, inasmuch as it was associated with typical secondary lesions. It must be remembered in this connection, that the duration of the disease is not always a criterion of the period at which the evolution of syphilis has arrived.

Eruptions characteristic of the secondary period may appear very early, or they may be retarded until long after their usual period of evolution. The point to which the evolutionary progression of syphilis has arrived, is often a better criterion of the pathologic age of the disease, than the period of time since infection.

#### TREATMENT OF NERVE DISEASE IN EARLY SYPHILIS.

The treatment of nerve disease in early syphilis is well understood to be that of the specific affection upon which it depends, hence a discussion of the therapeutics of the subject may seem to be a work of supererogation. There are, nevertheless, numerous highly practical points which are quite generally overlooked.

Prophylaxis of nerve disorder is an important feature in all cases of syphilis. It is to be remembered that the nerve disturbances of the early period are not only important *per se*, but they may constitute the point of departure for later and more serious disease. It is well also to bear in mind that certain factors may produce nervous disturbances which do not at the time produce symptoms, but which none the less lay the groundwork for serious organic nervous disease at a later period.

Inasmuch as vasomotor neurosis is probably an important factor in syphilitic nerve phenomena, avoidance of all causes of disturbances of the sympathetic is a prime indication. Instability of vasomotor equilibrium may often be avoided. Most surgeons are aware that tobacco and liquor are injurious to syphilitics, but comparatively few could give other than empirical reasons therefore. The toxic effect of these drugs upon nerve protoplasm and upon the sympathetic ganglia is a very powerful predisposing factor in brain and nerve disease in syphilis. By them the foundation is often laid for subsequent disease of a very serious or even fatal character. Mental worry or overstrain, mental excitement and sexual excesses constitute powerful predisposing factors,—especially to cord disease. If the patient be given a clear understanding of the true reasons for abstinence from these injurious factors he is likely to be much more tractable. In cases with a distinct neuropathic taint, hereditary or otherwise, the points which have been made are of special importance.

The curative treatment is in the majority of cases mercurial, first, last and all the time, but there are

certain special therapeutic features which are of greater importance than in other phenomena of syphilis. In the ordinary forms of syphilitic phenomena, a moderately active course of treatment usually suffices and a few days delay in getting the disease well in hand, is of no consequence. When nerve involvement exists, the treatment must be very energetic indeed, if we would avoid irreparable damage to delicate and important nerve and brain structures. The problem in such cases is, how to get the patient under the full physiologic effects of mercury most speedily. As a rule, internal medication alone can not be relied on; some patients and especially those with nerve phenomena can not tolerate the internal use of the drug at all. The hypodermic method is much quicker and more reliable, but not all patients will submit to it. Taken all in all, the inunction method usually proves the most satisfactory. Where practicable, the internal use of the protiodid is combined with it. A point of practical value is the fact that the drug acts best when applied as nearly as possible to the location of the nerve implication. Inunction of the neck and scalp are most efficacious in cerebral disturbance, while inunction of the region of the spine is quite effective in cord symptoms. It is necessary to practice inunction elsewhere, in order that a sufficient quantity may be absorbed.

Cases are met with in which mercury seems to be ineffectual and we are compelled to use the iodids. Such cases are rare, so rare that I suspect some of them to be instances in which the fault lies, not with mercury, but with the manner of its use. While the mainstay of treatment is mercury, there are certain adjuvants which are of great value. It very often happens that a case which appears resistant to mercury, yields quite readily when some one or more of the adjuvant methods are used.

As regards the general treatment, hot baths and laxatives constitute the most valuable accessory measures. The hot bath is especially useful, and is too often forgotten. Measures of counter-irritation and derivation are often of value in early nerve syphilis. Local or even general depletion may be justifiable. If I were to treat several of my cases over again, I should certainly apply leeches to the neck and possibly even perform venesection. Depletion certainly seems logical enough to warrant a trial. Electricity, massage and counter-irritation are often of service in bringing under subjection stubborn symptoms with a tendency to chronicity.

It has occurred to me that we have specialized too much in our management of syphilis. We are so imbued with the view that mercury is the only remedy for the disease, that our treatment is likely to consist of mercury throughout. A remedy which appears to me to be of great service in syphilis is gold. It has been my custom until recently, to prescribe the double chlorid of gold and sodium from time to time in nearly all my cases of syphilis. It has seemed of special value as a tonic and alterative in cases with a tendency to nerve involvement. Gold is a remedy which has been greatly neglected, and it is a matter of surprise that so few good preparations of the metal are on the market.

Within the past few months I have been using the bromid of gold and arsenic and bromid of gold and mercury—(Barclay's formulæ) instead of the sodium salt, and with gratifying results. The gold seems to have a special effect preventing sclerotic changes in

the tissues affected by the syphilitic neoplasm. The bromid in the combination may be of service in correcting vasomotor perturbations which probably exist in early nerve syphilis.

It is not my custom to advocate special preparations or formulas, but there is another preparation which I do not hesitate to recommend as a tonic and alterative in syphilis, especially where nerve disturbance exists. The preparation known as the three chlorids of mercury, iron and arsenic, (Renz and Henry's formula) has in my hands proved a reliable addition to the therapy of syphilis. It has the merit of elegance and definite dosage.

The question now arises, How long shall this treatment be continued? As a matter of principle, I believe that any course of treatment of less than three years duration is open to criticism. I am especially inclined to be dogmatic in regard to cases presenting early nerve or brain symptoms.

I have been much impressed by some of Mr. Hutchinson's cases of nerve syphilis. It appeared to me that some of them might have been avoided by proper management. Hutchinson's treatment is largely symptomatic. If at the end of a six months' course the symptoms have disappeared, treatment is stopped, to be resumed only on the recurrence of symptoms. Steady systematic treatment by mercury, iodids and gold, is the sole assurance of safety for the syphilitic.

As for the results of this plan I have only this to say: After some years of experience with syphilis, I have rarely seen of late, visceral, bone, nerve, or brain involvement in cases in which my instructions have been carried out to the letter. Cases occasionally arise in which a tonic stimulant becomes necessary. Under such circumstances, I have found the wine and fluid extract of coca of great service.

Anemia is sometimes a very important factor in early nerve syphilis. Such cases demand iron and strychnia. The iron may sometimes be combined with the mercury in the form of the pil. duo (mercurial pill with exiccated sulphate of iron). Some cases may require alcoholic stimulants in small amount.

Great care should be exhibited in the management of debilitated syphilitics, else harm may be done by our specifics.

## A SET OF UTERINE DILATORS.

BY HENRY T. BYFORD, M.D.

[From the Transactions of the Chicago Gynecological Society, Jan 18, 1895.]

I have here a set of uterine dilators, designed for the purpose of keeping the cervix moderately dilated

and thus maintaining uterine drainage in cases of endometritis with imperfectly developed or contracted cervixes. These are stiff in the center, but will bend quite easily on the end. They can be used in a retroverted or an anteverted uterus. In my office practice

I use the two smaller sizes, and the larger ones after curettage to keep a poorly developed cervix dilated until the tendency to contract passes off. It is passed through the internal os twice a week, for a few times, and later once a week until the dilatation has been maintained for three or four months. The vaginal fornices should be cleansed with a 5 per cent. solution of carbolic acid before they are introduced and an intra-uterine application of a 25 per cent. solution of ichthyol in glycerin be made after their withdrawal.

## SOCIETY PROCEEDINGS.

### Proceedings of the First Meeting of the American Academy of Railway Surgeons.

Held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.

(Continued from page 212.)

FIFTH SESSION, SATURDAY, NOVEMBER 10, 2 P.M.

CHAIRMAN DR. H. J. MAYNARD read a letter from Dr. M. Cavana, Surgeon N. Y. P. & O. R'y, Oneida, N. Y., expressing his regrets that on account of serious sickness in his family he was unable to be present but wished the Academy Godspeed.

The Academy then went into executive session to consider the applications of Drs. C. B. Parker, Surgeon, L. S. & M. S. R'y, Cleveland, Ohio; R. H. Taylor, Surgeon, Central R'y of Georgia, Griffin, Ga.; Geo. W. Crile, Surgeon, C. C. C. & St. L. R'y, Cleveland, Ohio; J. G. Davis, Chief Surgeon L. N. A. & C. R'y, Chicago, Ill.; A. D. Bevan, Chief Surgeon, Iowa Central R'y, Chicago, Ill.

The ballot having been cast it was found that all of the gentlemen named had been elected to fellowship.

### THE USE OF HORSE HAIR IN SURGERY.

BY C. M. DANIELS, M.D.

CHIEF SURGEON W. N. Y. & P. R'y, BUFFALO, N. Y.

In presenting this subject I lay no claim to originality in the use of horse hair in surgical practice as it was suggested to me ten years ago; but having used it extensively during the period mentioned, and not having seen the subject referred to but once in surgical literature, I venture to present this paper which will certainly be commended for its brevity.

For many years, surgeons have been faithfully searching for the ideal suture, one that would be non-irritating, small in caliber, easily adjusted and afford the closest approximation of the skin layers, and this with especial reference to wounds of the face or exposed parts where the avoidance of scars, more or less unsightly, is a great desideratum.

Catgut, silk and silkworm gut have long been used, but in the first we have a rapidity of softening and relaxation that will not infrequently result in a gaping wound. In the second, the resulting "stitch marks" which are frequently long in disappearing added to the occasional irritation, and in the silkworm gut the rigidity of the suture itself makes each undesirable in superficial wounds and all usually require dressings or coverings held by bandages which are both disagreeable and cumbersome, especially when the patient is able to be about or upon the street. I speak with special reference to those wounds which in themselves are not serious enough to confine the patient, this being the class of cases where I feel free to recommend horse hair sutures and upon which I note the following points:

1. Instead of a large or medium sized needle as required with even small strands of catgut, silk or silkworm gut, with the horse hair a small eye needle, curved or straight, according to the preference of the surgeon, can be used and thus minimize the size of each puncture of the skin.

2. Horse hair, when prepared as I will suggest later, has a firmness that will give support to the skin and very materially aid in keeping in approximation the edges of the same, and more nearly resemble silkworm gut in its action in the tissue.

3. Where wounds are both lacerated and contused, with

the fine needle, we can pick up many small but valuable parts which may be saved by gentle adjustment, and I will mention here that success, in any case, depends upon the care used in the introduction on one side, and exit on the other, of the needle near the margin of the cut or torn surface which should always be at right angles to the incision or skin margin, so that when the tie is made the strand will be of the same length upon the under as upon the upper side, and at a little to one side of the wound line.

4. Horse hair sutures can be placed much closer together than other suture material, with less danger of strangulation of the skin margins, this in itself better assuring perfection of adjustment and more satisfactory results and a "reef" or "granny" knot only is required being smaller than the ordinary surgical tie.

5. Horse hair *will not* bear any great amount of tension and could hardly be recommended for use in the flaps after a major amputation, except to place between other sutures for the purpose of more carefully approximating the skin margins.

6. After the introduction of horse hair, the skin being accurately adjusted and operation having been performed under the aseptic surgical procedures of to-day, except in extensive injuries, no dressing is required other than carefully drying the parts and brushing over with a layer of aseptic flexible collodion which, as it dries, will aid the horse hair in holding the skin in position.

With special reference to facial wounds, the field for the fastidious surgeon is here a great one, as horse hair at almost any hue of fast colors can be obtained, and he can place almost invisible stitches, from the color of the skin of the albino to that of the darkest African.

And now a word relative to the preparation of horse hair for surgical use: The convenience of the stable places it in every surgeon's hands and the hair needs only a thorough washing with soap and water, then for two or three days in 1 to 1,000 hydrarg. bichlor. solution and transferred to 95 per cent. alcohol until used. I believe that when this material is more generally used and appreciated that surgical supply houses will place it upon the market, and I have already made such a suggestion to one of them and without hope of future reward.

#### DISCUSSION.

DR. R. S. HARNDEN, Waverly, N. Y.—The use of horse hair as a suture is to me a recent thing, and only by the advice of Dr. Daniels did I begin its use, something like a year ago. The Doctor gave me sutures at a meeting of the Academy of Medicine in New York. I tried it, and while I feel like praising the suture, I would at the same time speak of its disadvantages. While it has many admirable qualities mentioned by the Doctor, the only objection to it that I could find is, that if you are not careful in using it in a wound that is likely to be attended with any tension, you will be disappointed in it as a suture. Bearing that point in mind, it is a valuable adjunct to our sutures.

DR. J. F. REGER, Littleton, W. Va.—A year or two ago I picked up a copy of the *British Medical Journal* and saw something in reference to the use of sterilized horse hair for injuries of the face, and I have had an opportunity of using it three times. I have found one thing, that whatever degree of tension you give the sutures in placing them you will retain that same degree of tension throughout the healing of the wound, as it never relaxes a particle that I have ever found, and it makes absolutely no stitch scar. While there may be some disadvantages in connection with its use, I have not as yet encountered them. I have found it excellent material for face wounds where we desire to avoid an unsightly cicatrix.

DR. A. C. SCOTT, Temple, Texas—When I was asked to discuss this paper, my first thought was to refuse to do it, inasmuch as knew so little about the subject. But I concluded that it would not be right to back down on an invitation of this kind, because I do not believe in backing down. I have never backed down but once in my life, and I do not want to do so in connection with the work of this Academy. I concluded that it would be better in attempting to discuss a paper of this kind to know very little about it in the be-

ginning. One could receive the points in this paper as they were put forth with an unbiassed mind. However, as soon as I came to Chicago I went to one of the public libraries and tried to find something on the subject, but found it was exceedingly difficult to do so in order to get anything satisfactory out of it. I find that horse hair ligatures are mentioned as a sort of side issue whenever the subject of ligatures is under discussion. It is mentioned in one of our works as a sort of drain, but it seems to be very unsatisfactory as a drain. I do not believe the essayist mentioned it as a drain at all.

DR. DANIELS—I intentionally left that out.

DR. SCOTT—For the purpose of drainage, I tried it some time ago, and it disappointed me in two respects: 1, I thought washing it with soap, and then boiling it for a while and dipping it into a solution of bichlorid of mercury would be sufficient to disinfect it. I was doing a Syme's amputation. To my surprise, I had more pus formation than I have had in a wound for many a day, and because of that fact the rest of the operation was watched very closely, everything rendered as aseptic as possible, and I can not help but think that the sepsis was due to imperfection in the horse hair.

2. That brought to my mind this thought, that when considering the use of horse hair we should take notice of the fact that it is subject to certain diseases, and if we are going to use horse hair extensively we will have to pay some attention to that one feature. It no doubt has some advantages. It is non-irritating when aseptic, and it leaves no scars. On that account it certainly has some advantages. Another advantage is that for surgeons who do a great deal of emergency work it is always easily obtained. In the case I speak of, where I used it for drainage in a Syme's amputation, in this instance, I had a beautiful result. I had no drainage tubes with me, and used the hair from my horse's tail which had been properly prepared before I had the operation completed. If the preparation I gave that was uncertain and the cause of suppuration in that case, I do not think it will do to prepare it so hastily as a rule. I have used horse hair in quite a number of circumcisions, and prepared it in those cases very much as the Doctor has suggested by washing it with soap first, then using the other disinfectants. I think the use of it is very limited, and should be, if it is used at all, confined to superficial wounds, particularly wounds of the face. Then we have to look very carefully for the tension which is apt to follow. I believe that one thing is the main bar to its use. The fact is that we have a certain amount of swelling in many of our wounds, and even if we have no swelling at all there is apt to be cutting of the tissues from it.

DR. REGER—Just one word in reference to the preparation of horse hair. I have never depended upon simply washing the hair, but I have sterilized it by superheated steam prior to using it, and I have never found it produce any sepsis whatever.

DR. DANIELS—I am very much gratified at the discussion that my paper has elicited. Dr. Harnden mentioned the point regarding tension. I also mentioned it in the paper. With reference to the preparation of horse hair, I will say that if it is properly and carefully prepared, thoroughly asepticized, the surgeon need not have any fear of sepsis following its use. In superficial wounds, where we can not place as many sutures of silk, catgut or silkworm gut in holding our flaps, we can use horse hair to excellent advantage.

On motion of DR. R. HARVEY REED, the chair appointed Dr. F. H. Peck, Clinton, N. Y., as sergeant-at-arms.

The election of officers having been made the special order of business at this session, on motion of Dr. F. H. Peck, the chairman appointed Dr. F. H. Caldwell, Sanford,

Fla.; Dr. W. H. Meyers, Meyersdale, Pa.; Dr. C. B. Kibler, Corry, Pa., tellers.

On motion of Dr. W. H. ELLIOTT, the Academy proceeded to ballot for officers without nomination.

The ballots for President resulted as follows: C. K. Cole, Helena, Mont, 18; H. J. Maynard, Cheyenne, Wyo., 3; C. M. Daniels, Buffalo, N. Y., 1; C. B. Parker, Cleveland, Ohio, 2; Scattering, 2.

On motion of Dr. F. H. CALDWELL, the election of Dr. C. K. Cole was made unanimous.

First ballot for Vice-President: W. H. Elliott, Savannah, Ga., 5; C. B. Parker, Cleveland, Ohio, 1; J. H. Maynard, Cheyenne, Wyo., 1; F. H. Caldwell, Sanford, Fla., 1; R. S. Harnden, Waverly, N. Y., 2; John E. Owens, Chicago, Ill., 4; C. M. Daniels, Buffalo, N. Y., 12; L. E. Lemen, Denver, Colo., 3; F. H. Peck, Clinton, N. Y., 1; R. Harvey Reed, Columbus, Ohio, 1.

There having been no choice, a second ballot was cast which resulted as follows: Dr. W. H. Elliott, Savannah, Ga., 13; Dr. C. M. Daniels, Buffalo, N. Y., 16.

On motion of Dr. W. H. ELLIOTT, the Secretary was instructed to cast the ballot of the Academy for Dr. C. M. Daniels for First Vice-President.

On motion of Dr. L. E. LEMEN, the Secretary was instructed to cast the ballot of the Academy for Dr. W. H. Elliott for second Vice-President.

Secretary: The ballot for Secretary resulted as follows: Webb J. Kelly, Galion, Ohio, 21; L. E. Lemen, Denver, Colo., 1; R. Harvey Reed, Columbus, Ohio, 6; A. C. Scott, Temple, Texas, 2. Dr. Webb J. Kelly was declared elected Secretary.

Treasurer: The ballot for Treasurer resulted as follows: F. H. Caldwell, Sanford, Fla., 1; R. Harvey Reed, Columbus, Ohio, 8; John E. Owens, Chicago, Ill., 7; F. H. Peck, Clinton, N. Y., 1; A. C. Scott, Temple, Texas, 1; C. B. Parker, Cleveland, Ohio, 1; C. B. Kibler, Corry, Pa., 9; W. H. Meyers, Meyersdale, Pa., 1.

On motion of Dr. F. H. CALDWELL, the Secretary was instructed to cast the ballot of the Academy for Dr. C. B. Kibler for Treasurer.

On motion of Dr. F. H. CALDWELL, Dr. R. Harvey Reed, Columbus, Ohio, was elected Editor.

Executive Board: On motion of Dr. MILTON JAY, Chief Surgeon, C. & E. I. R'y, Chicago, Ill., the candidate receiving the greatest number of votes would serve for four (4) years, the next highest for three (3) years, the next highest for two (2) years, and the next highest for one (1) year.

The ballot resulted as follows: John E. Owens, Chicago, Ill., 26; L. E. Lemen, Denver, Colo., 17; C. D. Evans, Columbus, Neb., 4; H. J. Maynard, Cheyenne, Wyo., 5; F. H. Caldwell, Sanford, Fla., 9; W. R. Blakeslee, Forest City, Pa., 1; F. H. Peck, Clinton, N. Y., 2; Geo. W. Crile, Cleveland, Ohio, 2; W. L. Buechner, Youngstown, Ohio, 2; C. B. Parker, Cleveland, Ohio, 17; R. S. Harnden, Waverly, N. Y., 14; A. C. Scott, Temple, Texas, 5; Chas. B. Fry, Mattoon, Ill., 1; D. C. Bryant, Omaha, Neb., 1; A. D. Bevan, Chicago, Ill., 1; S. G. Worley, St. Augustine, Fla., 1; J. G. Davis, Chicago, Ill., 1.

[In this ballot each Fellow had the right, if he so desired, to cast a ballot for four different Fellows to serve on the Executive Board.—ED.]

On motion of Dr. C. K. COLE, Dr. L. E. Lemen and Dr. C. B. Parker decided by lot who should serve as three years, Dr. Lemen being fortunate, secured the three-year term.

On motion of Dr. R. S. HARNDEN, seconded by Dr. R. Harvey Reed, Chicago was selected as the next place of meeting.

On motion of Dr. CHAS. B. FRY, the Executive Board was instructed to name the date for the next meeting which they did by selecting the second Thursday, Friday and Saturday of September, 1895.

Dr. GEORGE CHAFFEE, Surgeon, L. I. R'y, Brooklyn, N. Y., being unable to be present and his paper being in the hands of the Secretary, on motion of Dr. R. S. Harnden it was read and referred to the Committee on Publication.

(To be continued.)

## Louisville Surgical Society.

This society was the guest of Dr. Jos. M. Mathews at his residence on Monday evening February 11, Dr. H. H. Grant in the chair. In the business meeting Dr. L. S. McMurtry was elected a member of the society, and Dr. J. M. Ray nominated as a candidate for membership to be voted on at the next meeting.

Dr. A. M. VANCE showed some incarcerated fat removed from a case of strangulated femoral hernia upon which he had operated an hour previously. The patient was a female 50 years of age, and twenty years previously, when hernia first appeared, Dr. Turner Anderson had tried to persuade the patient to submit to an operation. Two of the patient's sisters also have femoral hernia. The hernia contained omentum and gut; the omentum was adherent, and was removed; gut had been strangulated for sixteen hours, and a great deal of unskillful taxis had been employed by the patient and her friends.

Dr. A. M. CARTLEDGE showed several specimens. One a large multinodular fibroid tumor removed from a negro woman, on February 2. The patient was 46 years of age with the appearance of being 60. Tumor had been noticed for six years. Indications for operation were the severe hemorrhages and the frequent attacks of peritonitis. This case had illustrated how difficult it is to follow hard and fast lines in hysterectomy; it is impossible to follow one operation. There were extensive adhesions on the posterior surface, and owing to the very short neck, there had to be almost a complete extirpation, leaving only a small ring of the cervix. The drainage was through the vagina, the two lower ligatures being drawn down into vagina, the others clipped close. The posterior drainage did admirably in this case, patient making an uninterrupted recovery.

Case 2.—This was the most wretched case of pelvic surgery the speaker had ever seen. History of an abortion two years ago. A septic fever following. Since that time she has fallen from 166 pounds to 130. In January she was seen by Dr. Cecil in an attack of peritonitis, and after treatment symptoms subsided and patient was up one day. She then had a set back, temperature rose to 104 degrees and there was considerable tympany. On January 29 the whole pelvis was one mass, the enlargement feeling like an extra-uterine pregnancy, the tumor rising to the umbilicus and to the right side. The condition was extreme. Immediate operation was decided upon. The peritoneum when cavity was opened looked like an extra-uterine pregnancy because of the black look and venous congestion present. Opaque lymph collections, three to four inches long, looking like a twisted ovarian tumor. The whole mass proved to be an enormous abscess extending over the uterus, and a left side pyosalpinx. The abscess on the right side contained fully a pint of pus. The intestines were cleaned as much as possible but left covered with organized lymph. Cavity was irrigated with many gallons of water, and dependent and upper drainage used. The specimens exhibited showed the adnexa removed. Patient made a good recovery.

Case 3—Illustrates a similar condition to the previous one. It dates from an abortion and tubular disease followed. Last of January during menstrual epoch had severe pain; a chill followed with an intense tension fever, and she had a feeling as if something gave way in her side, this giving some ease; general tympany followed. February 3 she was operated on, a general peritonitis existed, temperature of 103 degrees. The left tube was found resting on the fundus, as large as a wrist. The relief experienced as reported above, was due to the rupture of the tube in the broad ligament. The right tube was the subject of salpingitis. This case was treated with anterior drainage. No trouble followed. In such cases it is impossible to remove the tube without losing pus, after it has ruptured into the broad ligament.

Case 4—Was one of recurrent appendicitis. Operated on in the fifth attack. Each previous one was typical. The temperature was 102 degrees. The appendix had ruptured and the abscess, which was capped down by omentum, contained one ounce of pus. There was pus also in the appendix. On the third day after the operation, the patient had a catarrhal jaundice, but made a good recovery.

Dr. J. S. CHENOWETH showed appendix removed from a boy 14 years of age, in the third distinct attack. The last attack there was rigidity of recti muscles; in the twenty-four hours the bowels moved three times, but the tender-

ness and pain increased. The operation was done; two inch incision; appendix was black from pressure and apparently gangrenous to base, and at two points the wall was as thin as paper. There were no adhesions, the appendix lying free in the cavity and stretching up in the incision in the peritoneum. Double ligatures were used, the stump inverted and sewed. On the eighth day there was an intercurrent attack of rheumatism, but in other respects the recovery was uneventful.

*Case 2.*—Patient 32 years old. No trouble till four months ago. There was vomiting and pain, but these were somewhat relieved when the bowels moved. The temperature was normal; abdomen distended; vomiting; pain over left side, but tenderness only on the right side. Abdomen was thick; a five inch incision was made and adhesions found toward the center of the abdomen, and the appendix was adherent to the ilium by its tip. It contained fifteen or twenty drops of pus. Gauze drain was used; abdomen closed with difficulty owing to tension from tympany. The pain, he explained, was due to the position of the appendix, situated as it was across the abdomen.

*Case 3.*—Was diagnosed as intestinal obstruction. On the sixth day a mass developed on the right side; pulse 130; temperature 102 degrees following a cold sweat. Pushing through the thin adhesions forward, about one pint of thin pus escaped. The omentum and appendix were tied off. There was an enterolith and two perforations. In this case there was fecal vomiting, and patient was delirious from sepsis. The next day after the operation the patient got out of bed despite the close watching given him. In twenty-four hours the patient's bowels moved and a good recovery was made.

#### DISCUSSION.

DR. TURNER ANDERSON said that the operation for multiple fibroids was very interesting. It is true that no special technique can be followed. The question of appendicitis is one of the greatest importance. His personal experience he acknowledged was queer. His opinion based on his knowledge of appendicitis in late years amounted to this, that the operation is justified only when it amounts to the opening of an abscess, when pus can be detected by external evidence. In the last four months he has seen three cases in which a tumor presented, and which would have been operated on by others, and all have recovered without cutting.

DR. W. C. DUGAN—The multiple fibroid is a beautiful specimen. The pedicle is difficult to deal with oftentimes and it is impossible to tell which operation is to be done before the abdomen is opened. In a case of his own, with a long pedicle, the tumor was easily removed and patient was up on the tenth day. In contrast, in another case the operation as done by Dr. Cartledge was performed, only the posterior drainage was not used, and the patient died from concealed hemorrhage. As to the cause of pain being referred to left side in appendicitis, he believes it is due to pressure on the lumbar plexus and not to the location of the appendix.

#### Louisville Academy of Medicine.

The regular meeting of the Academy was held Feb. 18, 1895, Dr. T. L. McDERMOTT, President, in the chair.

DR. W. C. DUGAN presented a case of a young man in whom he done Bassini's operation for the radical cure of hernia two years ago. The patient at that time could not wear a truss, there being an undescended testicle. The testicle which was undeveloped was removed, the cord was cut off and the canal sewed up high up. The disposition of the cord is the great question, and if we could do away with the operation on the cord it would be a radical procedure. The only feasible plan is the return of the testicle to the abdominal cavity, and if the testicle is returned and placed in the sub-peritoneal space there would be no trouble in any case, unless there occurs a gonorrheal epididymitis as in a case by Dr. Palmer, and if this procedure is adopted, there will be a radical cure.

DR. E. R. PALMER wished to offer himself as a case of cure of hernia without operative interference. Through youth and early manhood he had been the subject of a right inguinal hernia, and always when laughing or at stool would place his hand so as to retain this hernia; in fact, his hand was on the internal ring nearly constantly, and a cure resulted. As regards the case mentioned by Dr. Dugan, he had a patient who was a monorchid; the left testicle was in the groin, and there was a gonorrheal epididymitis in the

retained testicle. It was swollen, and painful, and presented all the radical symptoms of an epididymitis in a descended testicle. Dr. Roberts in consultation advised waiting for subsidence of the acute inflammatory symptoms before recovering the testicle, but symptoms became aggravated and a castration was done. The testicle was the size of a small olive, the globus major and minor were the seat of a severe inflammation. At present the specimen is being prepared for a microscopic examination. In thirty years' experience this was the first case of gonorrheal epididymitis in a monorchid seen by Dr. Palmer.

DR. W. L. RODMAN stated that one of the drawbacks to the removal of an undescended testicle was the probability of having a hernia. He had a case, a cryptorchid; one testicle being in the left inguinal canal, the other in the right external abdominal ring, and on account of the irritation resulting from constant pressure the patient applied for relief. The last case he had operated on for an undescended testicle was promptly followed by a hernia, the cause most likely being on account of the removal of the testicle which acts as a plug, and when removed the canal is larger than usual, and a hernia results.

DR. DUGAN in closing the discussion upon the exhibited case, stated that he always closes up the ring; he slits up the canal to the internal abdominal ring, ties the cord off within the space behind the muscle, and does a Bassini operation.

DR. L. S. McMURTRY exhibited a specimen of a large uterine fibro-myoma. The patient was 37 years of age. The tumor had been present for three years, and had recently grown rapidly. The indications for operative interference were pressure symptoms and metrorrhagia. She was vomiting daily owing to pressure upon the stomach; there was very frequent urination owing to pressure on the bladder, and there was partial obstruction of the bowel necessitating a daily enema. An interesting point in the operation was the carrying upward of the bladder as the tumor grew, and unless care had been observed it might readily have been cut into. The peritoneum was slipped off, the bladder in this way was let down, the broad ligaments were tied off, and the tumor removed; the pedicle being treated extra-peritoneally with the nœud. There were extensive omental adhesions which had to be tied off separately. The operation lasted forty-two minutes and the patient left the table with a pulse of 78. The tumor, as shown, had grown in the direction of least resistance, the larger nodule had grown in the hollow of the sacrum, conforming to it in shape; the growth filled the pelvic cavity and the greater part of the abdominal cavity. This tumor belongs to that class of uterine fibroids which can only be cured by hysterectomy.

DR. DUGAN stated that the specimen was a beautiful one. He spoke of the attachments to the bladder and the rectum, and emphasized the fact that there is danger of cutting into the bladder, citing an instance of an operator who thought he was observing all precautions and still cut into the bladder, and he had seen in New York in the same operating room two cases in which the bladders had been cut into. It is so easy to let away the bladder and the rectum by making an incision and stripping off the peritoneum as was done by Dr. McMurtry.

DR. McMURTRY, in closing, said that in an exhaustive study of fibroids of the uterus, he had thought it strange how universally the profession was misled about fibroids disappearing at the menopause. He can not recall a half dozen in which the tumor had disappeared at the menopause. The most difficult case he had ever operated on the tumor rose to the diaphragm, and the body of the tumor had undergone cystic and purulent degeneration. The patient was obliged to lie on her side constantly, and weighed only ninety pounds when the tumor was removed, yet this patient was 52 years old and the growth first appeared a year before the menopause, and grew most rapidly after that period. It is rare that the menopause brings the desired relief by shrinkage of the tumor; it perhaps does not grow so rapidly, but the idea that they disappear rapidly is an error.

DR. LOUIS FRANK stated that in these cases of fibroids the danger of ligating the uterus is a point to be considered. As a rule, if the tumor is situated in the upper part of the uterus they usually do decrease in size at the menopause but do not disappear. If adhesions are present a more rapid growth can be expected, owing to the blood supply through these adhesions.

The paper of the evening by Dr. E. R. PALMER, on "The Vaginal Douche in its Relations to Blennorrhœa in the Female," was then read. [It will be published in this Journal later.]

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MARCH 2, 1895.

THE REGULATION OF DOCTORS' FEES.

Be cunning in the working this, and thy fee is a thousand ducats.—*Much Ado About Nothing*.

A member of the Illinois State Senate whom we may term O'DWYER, has introduced a bill into the Senate regulating the fees of physicians and surgeons. The JOURNAL has not been favored with a copy of this bill, but we learn by the daily press that the bill proposes to fix the maximum fee for any surgical operation at \$100. SENATOR O'DWYER is given credit by the veracious chronicler of the press for being the first to bring this subject to the attention of the law.

As usual, however, this statement was evidently made by some one who had not looked into the records on this subject. Professional fees have been regulated by law from perhaps the earliest times.

By the Cincian law, passed in the palmy days of the Roman Republic, lawyers were prohibited from taking fees or presents from those who consulted them; this, in effect, restricted the practice of law to those wealthy citizens who practiced solely from a desire to benefit their fellow men or the State. AUGUSTUS enforced the law by enacting as a penalty for its violation, that such violators should restore fourfold.

Under later Emperors, lawyers were permitted to take fees, and we are told by JUVENAL that pleadings had become venal, that persons of the lowest rank had become lawyers, and that they fomented lawsuits. According to PLINY, all subsequent edicts to restrain the rapacity of the lawyers were artfully eluded.

The precedent thus being set to control "the rapacity of the lawyers," it would be strange if there were not equal restrictions placed upon the doctors. But our profession had always been liberal and

indulgent, with a notable exception to be hereafter mentioned, and it was not until the eighth century that we find any laws concerning their fees. In that century a law was passed in Naples giving certain privileges to the universities of the kingdom, and the Salernian and Neapolitan physicians were compelled to make a visit in the city for a *demi-tarenus*, and if called without the city they were not allowed more than three *tareni*. The *tarenus* had a value of about thirty cents.

This was a distinct retrograde from that historic fee of MELAMPUS who flourished 1,380 years B. C. MELAMPUS having cured of insanity, the two daughters of the king, asked for and received a share of the kingdom for himself and his brother BIAS, and "they espoused the two daughters." But low as the fees were in the days of the SCHOOL OF SALERNUM, that faculty would seem to have had difficulty in collecting what they earned, for in a famous exhortation appropriately written in Leonine verse, "On the Ingratitude of Patients," they inveigh against the innate tendency of mankind to neglect the payment of any sum, either large or small, and they urge the physician to demand the fee "while yet the smart remains," or else the ungrateful patient will exclaim that he has paid, "twice paid, the costly bill." But there has never been any fixed price for special and peculiar services, according to ARBUTHNOT. Even in the first century the physician to a prince received about 250 sesteria (\$10,090). STERTENIUS complained that he had only a salary of 500 sesteria, when he at the same time had by his private practice alone, 600 sesteria.

But there can not even now be placed a limit to the actual value of services any more than a maximum limitation can be placed on individual knowledge, and we presume even SENATOR O'DWYER would wish the average physician to exceed the knowledge of the ancient surgeons of Scotland, for we are informed that when the surgeons of Edinburgh were incorporated in 1805, it was required of them that they should "rede and rite, know anatomie, nature and complexion of humanis bodie, and lykawayes to know all vaynes of the samyn, that he may make flew-bothemie in dew time," and also know the shaving of beards.

Fees will always vary according to the attainments, skill and characteristics of the practitioner and no legislative enactment can change the common custom of centuries. Nor is it possible, like the harlequin of the French comedy, to return the service of the physician. Harlequin having refused to pay the doctor, that worthy brought suit, whereupon being brought before the judge the quondam patient declares that he does not desire the health he had received and proposed to return it, and offered to deliver it into the hands of the judge, provided the doctor

would do the same with the disease, so that each might have his own. This time it was the judge who objected.

If the learned Senator will devote more time to the study of the real abuses from which the people suffer at the hands of monopolies, fostered by the lawyers, he will have less time to give to a profession that already gives nearly or quite one-half of its time to the service of the poor.

Whoever heard of a lawyer who gave any considerable time to the service of impecunious clients with not even a speculative fee in sight? The two law dispensaries, one by the University of Pennsylvania, and one by the Northwestern University, are said to be principally managed by students. The great surgeons, those who command the highest fees from patients able to pay, operate without fee or hope of reward on every person who asks them, provided only that they frankly state their inability to pay. That they are frequently imposed upon, there is no doubt. The same rule exists in the case of the specialists in the various branches of general medicine and surgery. We have thought, therefore, that the best thing about the bill of SENATOR O'DWYER was the impossibility of its passage, by any assemblage outside of a lunatic asylum.

#### THE KILLING OF DR. DYAS, AND ITS LESSON.

Nowhere in any civilized country is human life so insecure as in the city of Chicago. This assertion, prompted by the recent tragic death of the venerable DR. DYAS, is made advisedly. It is not only in the matter of homicide with criminal intent—of which the JOURNAL may have something to say hereafter—that it is the most blood-guilty city on earth, but in the matter of purposeless and wholly unnecessary homicide by common carriers Chicago has for years maintained a murderous preëminence.

Last year, 1894, no less than 308 human lives were crushed out by the railroads within the city limits, in addition to which there were 46 others killed by the street cars. This frightful total—which, it should be noted, is below the average—takes no account of the maimed and mangled survivors, who, it is estimated from the meager newspaper reports and the police and hospital records, number at least ten to every one killed outright. And of these survivors many are more to be commiserated than those to whom death came mercifully because swiftly.

In the previous year, 462 persons were killed by these common carriers, or nearly one-third the total number of deaths from all forms of violence. Under the caption, "Railroad Slaughter," the Commissioner of Health in his Annual Report, points out that this sacrifice of human life is due to the fact that there are over two thousand miles of railroad tracks within the corporate limits of the city, with more than three

thousand street-crossings at grade, over which nearly one thousand, four hundred trains run daily; and adds: "These accidents and the resulting slaughter and disabilities can not, probably, wholly or in any large measure, be obviated without an abandonment of the surface crossings; but it may be noted that one of the main lines east from Chicago, using the block system of signals, claims to have carried 428,000 passengers during the World's Fair period without injury to a single individual." And yet not only does the municipality neglect to enforce the use of the block-signal system on the railroads within the city limits, but it does not even compel the companies to maintain gates or other safeguards at these crossings, nor to employ signal men to warn of the approach of these rapidly-moving engines of death and destruction.

DR. DYAS'S murder differs not one whit from hundreds of others, save in his distinguished personality. Returning to his home in the six-o'clock gloom of a winter evening, after a day spent in philanthropic labors, he stepped from his train, unimpeded by bar or gate, unwarned by voice or signal; was struck down by the engine of a fast express train, and was found some time after, mangled and unconscious, his face crushed into the cinders and ballast of the road-bed, his neck broken, his skull fractured, his left hand ground to pulp by the flying wheels. At the inquest it was shown that there was neither gate, nor signal light, nor alarm bell, nor watchman to warn him or other passengers that a through express train was whirling down the tracks they must cross to reach their homes.

And neither coroner's jury, nor the daily press, nor the civic authority finds anything to do or say in the premises beyond a mild censure of the railroad company for "running the train, which killed the deceased, at a rate of speed entirely too fast to be consistent with the safety of passengers alighting at this station," and for not providing proper platforms at the station.

It should be recorded, however, in justice to the present municipal administration and to the memory of its predecessor, and as well to the railroad companies themselves, that progress is being made toward track elevation—a feat which may, possibly, be accomplished some time in the next century, certainly not much before. Is it too much to ask that, meantime, efficient guards, both mechanical and human, be placed at these surface crossings? Or, in the language of one of the leading dailies of the city, "Shall the grade-crossing slaughter go on, day in and day out, to the utter confusion of the claim that this is a civilized community?"

Blank Applications for membership in the Association at the JOURNAL office.

### THE FRENCH CABINET.

Our esteemed contemporary, the *British Medical Journal*, in a recent issue points out that "the new French cabinet includes two members of the medical profession, DR. CHAUMPS, Minister for the Colonies, and DR. GADAD, Minister of Agriculture. The *Journal* further states that there were "also two members of the medical profession in M. DUPUY's cabinet, namely, DRs. LOURTIES and VIGER."

In the United States we recall but a single instance of a medical man serving as a cabinet officer, that of DR. OLIVER WOLCOTT, of Connecticut, who was appointed Secretary of the Treasury next succeeding ALEXANDER HAMILTON, Feb. 3, 1795, GENERAL WASHINGTON then being President. PRESIDENT JEFFERSON continued DR. WOLCOTT in office and he held it until May, 1800. It is thus seen that unlike some of his successors, the Father of his Country had no objection to placing important public interests in the hands of a medical man, although it is only fair to mention that our DR. WOLCOTT had served with great distinction in the War of the Revolution and rose to the rank of Brigadier General.

In the Judiciary, one of its ablest members was the late MR. JUSTICE MILLER, of the Supreme Court, who was graduated in medicine at the Transylvania University, and who practiced medicine for nearly twenty years, before studying law and being admitted to the bar.

The legislative branch of the Government shows a great many who were medical men, but not very many who had risen to distinction in the medical profession. DR. SAMUEL LATHAM MITCHELL, editor of the *Medical Repository*, was a notable exception, for he not only made a phenomenally great record in his profession, but also in the Senate, being a Senator from the State of New York from 1804 to 1809. He also served in the House of Representatives from 1801 to 1804, and again from 1810 to 1813.

### THE JOURNAL OF THE ASSOCIATION.

We have cause for rejoicing that amid all the dullness of the great financial depression, the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is still gaining new members for the ASSOCIATION, and friends for itself. One enthusiastic friend has paid his subscription in full without discount, to the year 1900. Another member has exerted himself to the extent of securing a number of new members, and all the old members have remained steadfast. The enlargement made last year has allowed the publication of more medical news, and items of general interest to the profession than ever before, and the present outlook is very favorable for a still greater enlargement from and after July next. There is no longer any question of the ability of the ASSOCIATION to own, maintain and publish one of the greatest of weekly medical

journals, and its capacity for putting forth creditable medical literature is prodigious.

With these facts before them, it is clearly a patriotic duty of the membership to use every means in their power, to push the good work of organization, in season and out of season, until their journal shall become the greatest medical journal on the habitable globe. We urge every individual member to say a word to his medical friends, in favor of the necessity of standing shoulder to shoulder in the proud and patriotic work of enlisting every worthy member of the American medical profession in the cause of medical organization. Organize! brethren, in solid phalanx for the advancement of American medicine and fall into line under the broad banner of fellowship in the AMERICAN MEDICAL ASSOCIATION! Do not rest until you have secured the adhesion and membership application of every medical man in America.

### THE SEMI-CENTENNIAL OF THE AMERICAN MEDICAL ASSOCIATION.

The excellent suggestion of DR. SAMUEL C. BUSEY, quoted in our last issue (page 296), that preparations should be made for a proper celebration of the semi-centennial anniversary of our ASSOCIATION should not be allowed to pass unheeded.

The long and eventful life of the ASSOCIATION, the great wisdom and foresight of its founders, the great advances in professional organization and work due to the persistent efforts of the ASSOCIATION, the solid and material gains to the profession itself, and the foundation of the JOURNAL, afford abundant material for glorification and a jubilee occasion.

It will be therefore in every way fitting that a strong committee be appointed at Baltimore to carry out DR. BUSEY's suggestion in a manner at once creditable to the ASSOCIATION and gratifying to the whole profession.

### CORRESPONDENCE.

#### Inebriety.

ORAN, Mo., Feb. 25, 1895.

To the Editor:—Is a man who has been confined in prison ten or twelve years and who has not drank a drop of liquor in all these years an inebriate? Thousands of drunkards have been imprisoned, and not allowed to drink, and after a number of years released well, so far as physical appearances would indicate. The extreme scientists may assert that such men are diseased because many, so soon as they are released get drunk. If carelessness for public opinion is indicative of disease, then drunkenness is possibly a disease too. The remedy is rather curious but it is very effective. It "almost hardly ever fails." Prisoners are rarely troubled with this malady after the first day in jail. The remedy that cures this malady in so short a time is rarely used in other diseases.

Moral suasion is another effective remedy in drunkenness, but does no good in pneumonia. I used to say that religion

cured more bad cases of inebriety than any other remedy, but my ultra scientific friend scared me off the track, by telling me I was "dogmatic" (whatever that may mean). They tell me that the cases I report as cured are only *apparently* well. I ask them now, how is it with the men who have been *scientifically* cured; are they well or only *apparently* well? There are relapses in both cases; does the relapse prove that no one has been cured? If such a theory is true, there is no way to tell when a case has been cured. If drunkenness is a *disease* and the inebriate is like the patient with typhoid fever, entirely irresponsible for his acts, it is high time that it should be known. There is no earthly use for courts of justice fooling away their time with business that belongs exclusively to the medical profession. There has been a great wrong done to drunkards and doctors too. The drunkard has been punished and the doctor has lost his legitimate fees. Lawyers are responsible for this. They knew all the time that the drunkard was only sick! And instead of sending for the doctor they send for a policeman, have the poor drunkard imprisoned and get a fee for having him released, when the proper thing was to send for a doctor who obtains a fee for his call and prescription and sends the man where he belongs (*to a hospital*) where he can be cured and the hospital doctor gets his proper fee.

I think the editor is striking out in the proper direction. If we can convince the people that the inebriate belongs exclusively to us we will soon have plenty of practice and money too. The inebriate has paid the legal profession and courts good wages all the time, and if we can turn this great source of wealth into its proper channel it will be a blessing to the profession. Start a petition to Congress, and have all physicians sign it. We have been imposed upon long enough and will fight for our rights.

Hurriedly submitted by

W. P. HOWLE, M.D.

### A Multiplex Stethoscope.

PHILADELPHIA, Feb. 17, 1895.

To the Editor:—The interesting communication of Dr. A. M. Corwin, in the JOURNAL for Feb. 16, 1895, upon a double binaural stethoscope prompts me to send you the accompanying cut of a multiplex binaural stethoscope, which I have been using with much satisfaction to the class and myself, at the Jefferson Medical College Hospital for some

months. By means of this instrument, which was made at my request by Mr. William Willis, a well-known instrument maker of Philadelphia, sixteen students can listen to the heart sounds or any other physical signs demonstrable by auscultation, if these sounds are not so indistinct as to be heard with difficulty even when using a single instrument. With large classes the difficulty is that only two or three men can listen to the heart sounds, while the description of the

case is fresh in their memories, but with this multiplex instrument a large number can listen at once with little inconvenience to the patient. If two instruments are employed, thirty-two men can hear the sounds without interfering with one another; the chest pieces taking up but little room and the tubes being made long enough to extend a considerable distance from the patient. These instruments work satisfactorily in direct proportion to the quality of the materials used in their construction and the care exercised in making the wooden chest piece. Very truly yours,

H. A. HARE, M.D.

### Lister's Method.

MILWAUKEE, WIS., Feb. 14, 1895.

To the Editor:—Will you kindly inform me what Lister's method of chromicizing catgut is and oblige

Yours, etc.,

D. T. SHIMONEK, M.D.

307 Grand Avenue.

ANSWER: Lucas-Championierre, in his work on the "Radical Cure of Hernia," thus gives the original formula of Lister, which Lucas-Championierre still adhered to in 1892:

Olive oil . . . . .	100
Acid carbolici cryst. . . . .	20
Water. . . . .	2

M.

Catgut should be immersed in this emulsion not less than six months. Before using the catgut it is soaked for a quarter of an hour in a carbolic acid solution 20 to 100.

### Correction—Diagnosis of Leprosy.

PHILADELPHIA, Feb. 25, 1895.

To the Editor:—I beg you will correct two typographical errors in my letter, published in the JOURNAL of February 23, concerning "Leprosy and its Diagnosis." The words "and the analgia" should read erythromelalgia, and "ainhumides" should read ainhumoides. The first error as it stands now, makes the reading incomprehensible and senseless.

Respectfully,

LOUIS A. DUHRING, M.D.

MORAL: Write so that it can be read. Had our esteemed correspondent written the original as plainly as he has written this one, he would have had no cause for complaint.—ED.

## ASSOCIATION NEWS.

### American Medical Association.

{ OFFICE OF THE PERMANENT SECRETARY.  
1400 Pine Street, PHILADELPHIA.

The forty-sixth annual session will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday, and Friday, June 7, 8, 9, 9, and 10, commencing on Tuesday, at 10 A.M.

"The delegates shall receive their appointment from permanently organized State medical societies, and such county and district medical societies as are recognized by representation in their respective State societies, and from the medical department of the Army and Navy, and the Marine-Hospital Service of the United States.

"Each State, county, and district medical society entitled to representation shall have the privilege of sending to the ASSOCIATION one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number: *Provided*, however, that the number of delegates for any particular State, Territory, county, city, or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the ASSOCIATION."

Members by Application.—Members by application shall consist of such members of the State, county, and district medical societies entitled to representation in this ASSOCIATION as shall make application in writing to the Treasurer, and accompany said application with a certificate of good standing, signed by the president and secretary of the society of which they are members, and the amount of the annual subscription fee, \$5. They shall have their names upon the

roll, and have all the rights and privileges accorded to permanent members, and shall retain their membership upon the same terms.

The following resolution was adopted at the Session of 1888:

*That in future, each delegate or permanent member shall, when he registers, also record the name of the Section, if any, that he will attend, and in which he will cast his vote for Section officers.*

Secretaries of medical societies, as above designated, are earnestly requested to forward, at once, lists of their delegates.

#### AMENDMENTS TO THE CONSTITUTION AND BY LAWS.

[Offered in 1892, and laid over from 1893 and 1894.]

Offered by Dr. C. A. L. REED—Amend Article II, Section 1, of the Regulations, by inserting after the words "United States," "the Dominion of Canada, Labrador, and Newfoundland," and that such other changes be made in the phraseology of the Regulations and By-Laws as to make the same conform to this contemplated enlarged jurisdiction of the Association.

By Dr. I. N. QUIMBY—"That Thursday morning's general session be omitted, and the time be devoted to sectional work."

By Drs. JOHN MORRIS and J. G. KIERNAN—Amend Section 7 of the Constitution, entitled, "the General Business Committee," as follows: "It shall be the future duty of the General Business Committee to make and present the nominations for the officers of the Association and its standing committees, and recommend the time and place for the meeting of the Association."

"The General Business Committee of the Association shall perform all duties hitherto performed by the Committee on Nominations, which is hereby abolished. All sections of the Constitution and By-Laws, or parts thereof, inconsistent with the amendment, are hereby repealed."

By Dr. F. F. DOW—Amendment to the Constitution, to be known as Article VIII, entitled: "The Code of Ethics:" "The relations of the physician to the patient, to the public, and to the profession require that he shall be of good moral character, and in his personal and professional conduct without reproach; that he shall avoid pretense and notoriety; that he shall properly qualify himself for professional duty by broad and liberal studies in letters, sciences and arts; that he shall employ reasonable and reputable methods of practice; that he shall respect the laws of the State; that he shall encourage efficient means for the enlightenment of public opinion regarding the responsibilities of medical men and the relation of the citizen to public health, for the cultivation of medical education, for the promotion of the interests, usefulness, and honor of the profession, for the emulation, concerted action, and friendly intercourse among those engaged in it."

"Substituting the Roman numerals IX for VIII."

"All articles, By-Laws, and Codes inconsistent with this amendment are hereby repealed."

By Dr. J. H. RAUCH—"That on and after July 1, 1897, no one will be admitted to membership in the AMERICAN MEDICAL ASSOCIATION who has not studied medicine for four years, and attended four annual courses of lectures of at least six months' duration."

By Dr. F. F. DOW—Amend By-Law No. XI, relating to the Judicial Council. The second clause of paragraph 3 shall be amended to read as follows: "The decisions of said Council on all matters referred to it by the Association shall be reported at the earliest practicable moment, and shall be final unless revised by the Association."

By Dr. A. B. HOSMER—"WHEREAS, The constantly increasing number of papers on general surgical subjects presented each year at the Surgical Section of this Association, the reading and even restricted discussion of which prohibit the introduction of any considerable number of papers on strictly orthopedic subjects, which might not prove of universal interest to the general surgeon; and

WHEREAS, There are already a sufficient and rapidly increasing number of members of the Surgical Section of this Association especially interested in this branch of surgery to warrant it; therefore be it

"Resolved, To amend Article II of the By-Laws by the addition, under the heading Sections, and after 12, Physiology and Dietetics, the following: 13, Orthopedic Surgery."

By Dr. J. T. PRIESTLEY—"The entire report on Constitution etc., as offered in the report of Dr. Holton at San Francisco."

#### ADDRESSES.

On General Medicine, by Dr. William E. Quine, Chicago, Ill.; on General Surgery, by Dr. C. A. Wheaton, St. Paul,

Minn.; on State Medicine, by Dr. H. D. Holton, Brattleboro, Vt. Committee of Arrangements, Dr. J. J. Chisolm, Chairman, Hotel Stafford, Baltimore, Md.

WILLIAM B. ATKINSON, M.D., Permanent Secretary.

#### EXTRACTS FROM BY-LAWS.

"The Chairman of each Section shall prepare an address on the recent advancements in the branches belonging to his Section, including suggestions in regard to improvements in methods of work, and present the same to the Section over which he presides, on the first day of the annual meeting. The reading of such address not to occupy more than forty minutes."—By-Laws.

"It shall be the duty of every member of the Association who proposes to present a paper or report to any one of the Sections, to forward either the paper, or a title indicative of its contents and length (not to exceed twenty minutes in reading), to the Secretary of said Section at least one month before the annual meeting at which the paper or report is to be read."—By-Laws.

4.—The Publication of Papers and Reports.—"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association, and shall be published and sold for the exclusive benefit of the Association."—By-Laws.

#### OFFICERS OF SECTIONS.

*Practice of Medicine.*—E. W. Kellogg, corner Mitchell Street and First Avenue, Milwaukee, Wis.; Wm. E. Quine, Secretary, 103 State Street, Chicago, Ill.

*Obstetrics and Diseases of Women.*—F. H. Martin, Chairman, 34 East Washington Street, Chicago, Ill.; X. O. Werder, Secretary, 514 Penn Avenue, Pittsburg, Pa.

*Surgery and Anatomy.*—Joseph Ransohoff, Chairman, 296 Walnut Street, Cincinnati, Ohio; Reginald H. Sayre, Secretary, 285 Fifth Avenue, New York.

*State Medicine.*—Liston H. Montgomery, Chairman, 70 State Street, Chicago, Ill.; Chas. H. Shepard, Secretary, 81 Columbia Heights, Brooklyn, N. Y.

*Ophthalmology.*—Edward Jackson, Chairman, Denver, Colo.; H. V. Wurdemann, Secretary, 805 Grand Avenue, Milwaukee, Wis.

*Laryngology and Otology.*—J. F. Fulton, Chairman, 326 Wabasha Street, St. Paul, Minn.; T. J. Gallaher, Secretary, 129 Collins Street, Pittsburg, Pa.

*Diseases of Children.*—Edward H. Small, Chairman, Penn and Negley Avenues, Pittsburg, Pa.; G. W. McNeil, Secretary, 280 Frankston Avenue, Pittsburg, Pa.

*Oral and Dental Surgery.*—M. H. Fletcher, Chairman, 65 West Seventh Street, Cincinnati, Ohio; E. S. Talbot, Secretary, 125 State Street, Chicago, Ill.

*Neurology and Medical Jurisprudence.*—Daniel R. Brower, Chairman, 34 East Washington Street, Chicago, Ill.; T. D. Crothers, Secretary, Walnut Hills Sanitarium, Hartford, Conn.

*Dermatology and Syphilography.*—A. E. Regensburger, Chairman, San Francisco, Cal.; D. H. Rand, Secretary, Portland, Ore.

*Materia Medica and Pharmacy.*—W. Helpsey, St. Louis, Chairman; G. F. Hanson, Secretary, 715 Clay Street, San Francisco, Cal.

*Physiology and Dietetics.*—M. H. Woolsey, Chairman, Oakland, Cal.; C. G. Chaddock, Secretary, 2900 Washington Avenue, St. Louis, Mo.

**Section on Gynecology.**—Dr. Charles Jacobs, the distinguished gynecologist of Brussels, will attend the meeting of the AMERICAN MEDICAL ASSOCIATION in Baltimore, and, if opportunity offers, will perform his operation of vaginal total extirpation of the uterus and appendages, before such of the members as desire to witness it.

**The Baltimore Meeting—Notice to Exhibitors.**—The Committee of Arrangements has rented the Cyclorama Building, for the pharmaceutical exhibit in connection with the meeting of the AMERICAN MEDICAL ASSOCIATION. This building is directly across the street from the new Music Hall, in which the meetings of the Association will be held. Intending exhibitors are requested to forward their applications for space at their earliest convenience. Diagrams, rates, etc., will be forwarded upon request. It is desired to make the exhibit of pharmaceutical products, instruments, etc., a special feature of the meeting. The Committee on Exhibits will do

all in its power to satisfy exhibitors, both as regards space conveniences for storage, and rates. At the same time it must be evident to every one that the first applicants will have first choice of position. The diagram of spaces will also show the location of the exhibition building in relation to the meeting hall, and the principal railroad stations.

All correspondence in reference to the exhibits should be addressed to the undersigned.

GEORGE H. ROHÉ, M.D.,  
Chairman Committee on Exhibits.

Hotel Stafford, Baltimore, Md.

**Section on Dermatology and Syphilography.**—List of papers to be read at the next meeting in Baltimore, in June: Chairman's address, and papers on "The Identity of Lupus Vulgaris Erythematous," by Alfred E. Regensburger, San Francisco, Cal.; "Keloid," by A. Ravogli, Cincinnati, Ohio; "The Human Epitrichium and its Relations to some Congenital Skin Diseases," (also Specimens), by A. H. Ohmann-Dumesnil, St. Louis, Mo.; "Adenoma Sebaceum," by W. E. Maxwell, Portland, Ore.; "Syphilis—the Dangers of and how to avoid Them," by A. S. Garnett, Hot Springs, Ark.; "Syphilis of the Pharynx," by A. Ravogli, Cincinnati, Ohio; "Syphilis and Gonorrhea as an Etiologic Factor in Diseases of Women," by H. R. Holmes, Portland, Ore.; "Syphilitic Specific Ulceration of the Rectum," by James P. Tuttle, New York City; "Conceptional Syphilis," by David H. Rand, Portland, Ore.; "Cerebral Syphilis," by Frank P. Norbury, Jacksonville, Ill.; "Hereditary Syphilis," by G. S. Stein, Columbus, Ohio; Edward Martin, Philadelphia, Pa., subject not stated; Jas. Nevins Hyde, Chicago, Ill., (promised) subject not stated; James E. White, Boston, Mass., (promised) subject not stated; W. A. Hardaway, St. Louis, Mo., subject not stated; Louis Franks, Milwaukee, Wis., subject not stated; W. F. Breakey, Ann Arbor, Mich., subject not stated; W. T. Corlett, Cleveland, Ohio, subject not stated; "Exhibition of Protozoa in three cases of Skin Disease," and "Some late and interesting points on the Pathology of Herpes Zoster," by T. E. Gilchrist, Baltimore, Md.; L. Duncan Bulkley, New York City, subject not stated, unless it be "Signs, Diagnosis and Treatment of Sycosis—Differential Diagnosis, Pathology, Local and Internal Treatment."

## BOOK NOTICES.

**Dose-Book and Manual of Prescription-Writing**, with a list of the official drugs and preparations, and also many of the newer remedies now frequently used, with their doses. By E. I. THORNTON, M.D., Ph.G. Philadelphia: W. B. Saunders. Chicago: The W. T. Keener Co. Price \$1.25.

The author says on page 21 concerning the metric system: "This system of weight, length and capacity has largely come into general use, and its adoption into the United States Pharmacopœia of 1890 makes it obligatory upon the physician to understand and *to be able to translate it into the ordinary apothecaries weights and measures, that he may be able to use it in prescribing.*" (Italics ours.) Such statements are absurd. Why should anybody wish to translate the metric dose into the obsolete British form? There is only one way to use the metric system of dosage, and that is to learn the single dose. One can, if he desire, carry a little dose slip in his visiting list or call book, on which is printed the dose of each drug in metric terms; let him consult it a few times and he will soon become familiar with the dosage of the more common drugs. Rules for conversion are tiresome and frequently lead into making fractional doses that are ridiculous and unnecessary.

The author very properly remarks that the decimal system is easy to learn, as it is as simple as our monetary system, but he might have said that it adds to the confusion to undertake to work out a complicated mathematical problem whenever one wishes to write a prescription. The space

devoted to these translations is therefore worse than useless. There is but one thing to remember, that is the single dose, then *multiply the single dose by the number of doses wanted*, point the decimal, by using a line instead of a point, to emphasize it, and the thing is done.

The directions for prescription writing are excellent and the excursion into Latin construction entirely proper, but the examples of prescriptions are all in the old dosage, with a solitary exception on page 147. A large part of the book is devoted to a dose list of the official drugs; both systems are used.

This book has a field, and with alterations in the directions indicated, will be well adapted to meet the necessities of the time.

**Doctor Judas; a Portrayal of the Opium Habit.** By WILLIAM ROSSER COBBE. Cl., pp. 320. Chicago: S. C. Griggs & Co. 1895.

The author has named opium, Doctor Judas, because while it cures or saves it betrays, and the whole of the book is devoted to setting forth the evils that the opium habit entails.

"Contention has been made," says the author, "that in the hands of physicians there is safety in its use. This is contrary to the evidence of numbers of former habitués, all of whom save two, had the habit fastened on them by their family doctors. Confirmation of the danger that comes from medical carelessness is had in a trustworthy record of more than twelve hundred cases, upward of 70 per centum of whom owed their serfdom to the same agent. It should be explained that many of those personally known, are themselves physicians who prescribed the drug that fastened the habit upon their souls."

Whether prepared to indorse *in toto* the author's faith, there can be no harm in obeying the mandate of Mr. Cobbe that "the opiate should never be given for a longer period than a week at the most, and the patient should be kept in absolute ignorance of the nature of the prescription. It is absurd to insist that the physician can shut off the use of it merely by refusing to give it any longer. What does the sick one care for the doctor's interdict, when he can buy enough at the nearest drug store to fix the habit upon a score of persons?"

The book seems to well portray the sad experiences of the unfortunate opium victim, and it is written with much power. The suggestion that there is a concealed advertisement for the one solitary doctor who alone can cure this disease, does not militate against the literary merit of the book. That it holds out a hope to the sufferer is true, but the author and his readers may as well put this thought "in their pipe and smoke it." That is, that in the present enlightened age, no one has a monopoly of knowledge of the means of cure, or of the method of its application.

**Charaka Samhita.**—The eleventh fasciculus of this ancient Hindu book lies on our table. It is fully as curious, and not less interesting than its predecessors. Much space is given to the dietary in this fasciculus. Fish is not to be eaten with milk, and "the meat of domesticated animals, of those that live in marshy regions, and of those that are aquatic, should never be taken in conjunction with such things as honey, sesame oil, molasses, milk, masha (*Phascolus radiatus*), mulaka (*Raphanus sativus*), tolu stalks, and such paddy as have put forth sprouts."

We shall find, if we strip the matter of its verbiage, that the ancient Hindus possessed a fair idea of digestion, and that they well grouped the different varieties of esculents according to their qualities. The code of health of Salernum, written during the Crusades, is not much nearer modern modes of expression than this most ancient of all medical books known to mankind. The learned Avinash Chandra Kaviratna has conferred great pleasure on medical scholars everywhere by making the Charaka Samhita accessible.

## PUBLIC HEALTH.

**High Death Rate in Chili.**—The heavy rate of mortality in Chili has led the Equitable Life Assurance Society to discontinue a further issue of policies in that republic.

**Bovine Tuberculosis in France.**—M. Alexandre in a report on the subject of tuberculosis in stables in the Department of the Seine, gives some interesting figures. He found the disease in seventy herds. Of 20,000 cows, only 68 were recognized as tuberculous, a proportion of 3.4 per 1,000. M. Alexandre therefore holds to his opinion that the consumption of the flesh and milk of our domestic animals is not the cause of the terrible mortality from tuberculosis among mankind. It is important, he says, that this once accepted belief be thoroughly rooted out of our minds. He urges, nevertheless, that modifications of the existing laws ought to be made at once, so as to make compulsory the employment of the tuberculin test on all animals of a herd in which a case of tuberculosis has been proved to exist.

**Tuberculosis in Germany.**—It is generally admitted that the mortality from pulmonary tuberculosis increases yearly, especially in large cities; but recent statistics collected by Professor Hollinger, of Munich (*Semaine Medicale*) seem to demolish this theory—at least so far as the principal German cities are concerned. For example, the mortality from tuberculosis in Munich, which was 40.8 per 10,000 inhabitants in 1883, had decreased to 30.8 in 1893; in Berlin the diminution has been 9 per 10,000 (25.7 in 1893 against 34.7 in 1883). A corresponding diminution has been shown for Frankfort, Dresden, Stuttgart and other cities. It is probable that there has been a similar reduction in other countries, for in Vienna during the same space of time the mortality from tuberculosis has been lowered from 69.29 to 47 per 10,000. This lowered mortality is undoubtedly due to the hygienic measures, individual and general, taken in regard to tuberculous patients. This is not the sole reason, however, for the deaths began to decrease before any vigorous prophylactic measures were instituted. Part of this decrease, then, should be attributed to the cleansing of the cities.

**An Antitoxin Plant at Brooklyn.**—By authority of the Mayor, a grant of \$10,000 has been given to the Brooklyn Department of Health for the establishment of a serum plant. This sum, it is believed will enable the bacteriologists of the Department to continue for one year with a twenty-horse stable. The authorities of the city were induced to take this action largely by reason of the representation of the medical societies and profession. The motive leading to this outlay has been the high prices that are still ruling and must, for a considerable period, continue to rule in the market for foreign serum; these prices being practically prohibitive to the poor and to institutions that have no funds for extraordinary remedial expenditures. At \$3.50 per bottle for the imported serum, the impecunious must do without, unless there are created local plants for the gratuitous distribution of the remedy. At Brooklyn a beginning has already been made with three horses. One of these latter is soon to be tested. It is reported that some few of the horses owned by the New York City Board of Health have already yielded a product fully equal to the strongest of the imported serums. The clinical results from the same quarter are reported as continuing favorable. There is now being constructed a chart for the purpose of graphically setting forth the decreased mortality by diphtheria that has followed the increased use of the antitoxin. There is no longer any doubt in the minds of the experts that the ratio of mortality has progressively fallen in proportion as the quantity of serum has become more and more accessible.

**Mortality of New York State in 1894.**—The Empire State had a total loss of 118,195 lives in the year 1894. This reported loss, plus an estimated deferred return of about 3,800 deaths, yields a death rate of 18.75 per 1,000 living. This is the lowest rate that has been recorded since 1889. There was a daily average of 324 deaths, as against 340 in 1893. The mortality under five years was 35.1 per cent. of the total; a point that had not been reached before in five years. Zymotic mortality was 18.6 per cent. of the total, or slightly above the average of the last five years. Diphtheria and croup caused 6,592 deaths or 96 per 100,000 population—the highest rate since 1889. This heightened prevalence and mortality was limited to the maritime district of the State, in which is included the cities of New York and Brooklyn. Typhoid fever caused 1,640 deaths; scarlet fever 1,227; measles 900; whooping cough 1,020. Smallpox caused only 27 deaths in the State at large; but 281 deaths occurred in the metropolitan center, total 308; only 60 deaths by that cause occurred in the last six months. Diarrheal diseases presented a high mortality, 8,956 deaths; malarial diseases 422; and cancer 3,305. Consumption caused 12,824 deaths, while acute respiratory affections were charged with 15,885. The mortality from consumption was equivalent to 108.46 out of every 1,000 deaths, an increase as compared with the totals for 1892 and 1893; a decrease as compared with the preceding years of that quinquennium. There were 3,000 deaths charged against epidemic influenza, or la grippe; which manifested its fifth recurrence, beginning in December, 1893, and lasting about four months. The epidemic was less widespread and less fatal than in certain former years, when as many as 5,000 and 8,000 deaths were referred thereto. The total of deaths cited as "unclassified," 15,310, is an enormously high unknown quantity, when a comparison of causes is in question. Old age is credited with 5,500 deaths, nearly; deaths by violence and accidents nearly the same total. The estimated population for the State is not given in the printed "Summary" recently distributed, but from the Fourteenth Annual Report of the Board of Health, we learn that the population was held to be 6,689,000, of which 3,350,600 dwelt in the maritime district.

**Sero-therapy and Sero-prophylaxis.**—MM. Le Breton and Magdelaine give an account in *Le Bulletin Medical* of their experiences with the diphtheria antitoxin in the Paris Hospital for Sick Children. The diphtheria pavilion is divided into two rooms, one for boys and one for girls, each of which has a small room for isolation. As all the children were placed before diagnosis in the same contaminated atmosphere the following routine was adopted: Every child admitted to the pavilion was given an injection of 10 to 20 c.c. of serum according to its condition or the probability of its having diphtheria; this was done as soon as the child was seen either by the authors or by one of the attachés of the Pasteur Institute. The injection was thus made before any bacteriologic diagnosis. If the tube, sown immediately, showed cultures of the Löffler bacillus on the second day, the injection marked the beginning of the curative treatment. In the contrary case, it was purely prophylactic and children thus protected were allowed to remain the length of time necessary for their cure and no case of contagion occurred in the hospital. No local treatment was used with the serum save irrigation with a weak Labarraque's solution (50 c.c. to 1,000), which has no therapeutic value and only served to detach the loosened membrane. General tonic treatment was instituted, both for the disease and for complications. There were 330 children admitted, 258 of whom had diphtheria. Of these 258 only 31 died—12 per 100, and if we omit eight cases dying in the first twenty-four hours the mortality is only 10.8 per cent. Tracheotomy was performed twenty-four times with nine deaths—37.5 per cent. Intubation was performed in fifty-one cases of diphtheria with fourteen deaths—27.45 per cent. Among these fourteen.

cases seven deaths occurred in less than twenty-four hours, so that there results, for serum-therapy and intubation, a mortality of only 18.1 per cent. This death rate is very low especially when the period covered is considered—the months of October, November and December—and the further fact that many of the cases were very grave, 147 out of the 258 having mixed infections and these furnished 19 out of the 31 deaths. The untoward effects of the serum were those previously noticed; in the 1,200 injections a slight redness developed at the site, but only one suppurated; some were followed by eruptions, (70 cases); in 140 cases albuminuria developed. The authors however, conclude that on account of the elevation in temperature and possible renal complications, that the serum should no longer be used as a preventive in children exposed to diphtheria.

**Epidemic Diseases.**—Notwithstanding an increasing prevalence of influenza, the general death rate is not materially affected by this disease, except as it occurs as a complication of pneumonia. Its incidence seems to be chiefly along the North Atlantic—New York and Washington being especially afflicted; but nowhere in this country has it attained the proportions which cable dispatches report in Great Britain, where it is estimated that about 15 per cent. of the population are sufferers from the malady. The well-informed London correspondent of the New York *Sun* reports that among those who are laid up with the distemper are Lord Roseberry, Mr. Balfour, Mr. Henry Irving, Lord Dunraven, forty-five members of the House of Commons, 20 to 40 per cent. of the staffs of the principal banks, and one-third of the judges of the high courts. The postal and telegraph services are seriously affected by the prostration of hundreds of employes by the disease. He adds that, "Mr. Walter Besant yesterday told of a golden wedding reception which was attended by one hundred guests a week ago. Ninety of these are now in bed with influenza. The number was increased to-day (February 24) to ninety-one, for Mr. Besant himself has been stricken." Dr. Andrew H. Smith, in the *Medical Record*, notes the changes of type that have occurred in the disease from year to year since 1889. At first, the respiratory conditions prevailed almost exclusively, but presently an abdominal form became frequent, and then cases were observed in which the nervous system seemed to bear the brunt of the attack. Before the close of the second epidemic these several types—respiratory, abdominal and nervous—were pretty generally recognized, and were sufficiently distinct to serve roughly as a basis of classification. By the third year the severity of the disease had greatly abated and the types became less characteristic. During the latter part of last year's epidemic, a purely tracheal cough became a leading feature. This year the same cough is present, but, in addition to it, there is a positive sense of soreness and discomfort in the trachea. Another peculiarity, more marked this year than before, is the occurrence of subnormal temperature after the subsidence of the febrile stage, suggesting the possibility of a production of secondary toxic material, having an action upon the heat centers directly opposite to that of the poison which was present at the beginning of the attack. This subnormal temperature may persist for a week or more, during which time there is no other evidence of disease, unless it be a feeling of lassitude, with more or less mental depression, and perhaps an excessive amount of phosphates in the urine. Dr. Smith urges that "the importance of avoiding exposure during convalescence can not be too strenuously enforced. In every case in which serious complications have arisen under my observation, they were due to lack of care in this respect. Too great haste to resume business or pleasure-seeking is responsible for most of the fatality of the gripe."

The recent severe weather has enormously increased the death rate from pneumonia and bronchitis, and among the aged. Diphtheria is declining in frequency and many observers note a lessening grade of severity. So marked has been the decline in some localities—New York for example—that the Boston *Medical and Surgical Journal* suggests a causal relation between this phenomenon and the increasing use of the antitoxin. Such relation is more than doubtful, however, at least in this country.

The smallpox wave appears to be moving southward; in St. Louis and other localities in the Mississippi valley, although official reports are wholly wanting, there is, un-

doubtedly, a serious increase in the prevalence of the disease. It is declining in Chicago, Milwaukee and Detroit; in the former city there were 20 new cases reported during the week ended February 27, making a total of 85 new cases during the month up to that date—total treated 202; discharged recovered 96, died 24, death rate 11.6 per cent. In Milwaukee on the 25th ult., there were thirty cases remaining—ten in hospital and twenty in homes; eight new cases reported during the week.

**Prevention of Blindness.**—In New Jersey the following law has been favorably considered by the committees in both Houses, and it is hoped it will become a law:

SENATE NO. 91, STATE OF NEW JERSEY.

Introduced Feb. 4, 1895, by Mr. Williams. Referred to the Committee on Miscellaneous Business.

An act for the prevention of blindness in the State of New Jersey.

SECTION 1.—Be it enacted by the Senate and General Assembly of the State of New Jersey, That should one or both eyes of an infant become inflamed, swollen or reddened, or show any unnatural discharge at any time within two weeks after its birth, and no legally qualified practitioner of medicine be in attendance upon the infant at the time, it shall be the duty of the midwife or nurse, attendant or relative having charge of such infant to report in writing, within six hours, to the local Board of Health of the city, township or other municipality in which the parents of the infant reside.

SEC. 2.—And be it enacted, That the said Board of Health shall direct the parents or persons having charge of such infant suffering from such inflammation, swelling, redness or unnatural discharge of the eye to immediately place it in charge of a legally qualified practitioner of medicine, or in charge of the physician of the city, township or other municipality if unable to pay for medical services.

SEC. 3.—And be it enacted, That every local Board of Health in the State of New Jersey shall furnish a copy of this act to every legally qualified practitioner of medicine, and to each person who is known to act as midwife or nurse, in the city, township or other municipality for which such Board of Health is appointed; and the Secretary of State shall cause a sufficient number of copies of this act to be printed, and to supply the same to such officers for distribution.

SEC. 4.—And be it enacted, That any failure to comply with the provisions of this act shall be punishable by a fine not to exceed two hundred dollars, or imprisonment not to exceed six months, or both, upon conviction under prosecution proceedings to be brought by any local Board of Health.

SEC. 5.—And be it enacted, That this act shall take effect and be in force on the first day of May, one thousand eight hundred and ninety-five.

The wording of this act is rather unusual, in that it imposes a penalty upon parents for the neglect of their children. This is apparently rather harsh, as it is naturally supposed that parents would do all in their power without the fear of any such law. The practical fact is, however, that this form of cruelty to children too often passes unnoticed and inasmuch as a large number of these individuals made blind by such neglect subsequently become charges upon the State, it is but right the State should recognize the danger and impose penalty upon parents, as well as nurses who are too ignorant or too negligent to take the precautions necessary. It is hoped that the bill will pass in its present form and it would be well if as strong a law could be enacted in other States.

## NECROLOGY.

LOUIS CONRAD, M.D., of Brooklyn, N. Y., died January 25, aged 37 years. He was a native of New Jersey, born of German parents, and had been in the practice of medicine since 1887, in which year he was graduated from the medical department of the New York University. His entire professional life had been passed in Brooklyn. His final illness was the result of an acute pulmonary tuberculosis that made its presence known about four months ago.

HENRY V. BYRNE, M.D., of Brooklyn, N.Y., February 17, the youngest son of Dr. John Byrne, the well-known gynecic surgeon of St. Mary's Hospital, has died at the early age of 24 years. He was graduated from the University of Vermont Medical Department in the class of 1892. He was a young physician of rare qualities and promise; his untimely death was due to pulmonary tuberculosis of about one year's duration.

FERDINAND WILLIAM OSTRANDER, M.D., the oldest physician of Brooklyn, died January 29, in consequence of an attack of influenza with certain of the complications incident to age. He was a native of New York City, born there over ninety years ago. He received, in 1828, his license to practice from the New York County Medical Society, which at that time had a legal status affording many rights and privileges not now possessed by the county organizations. He was for sixty-two years a resident of Brooklyn, with a very considerable practice among the old Long Island families. Not a few members of the Ostrander family have followed honorably the profession of medicine. The subject of this notice has surviving him a son who is a physician in the same city. Dr. Ostrander retired from active practice about ten years since. In 1835, when an epidemic of cholera afflicted the western end of Long Island, he was one of the staff of physicians officially engaged to care for the sick of the village of Brooklyn; it is recorded that there were ninety cases, with thirty-five deaths. He was a member of his county medical society over sixty years.

ROBERT GRAFTON NOLAN, M.D., of Bergen Point, New Jersey, died, aged 38 years, Jan. 23, 1895. He took his medical degree in 1877 at the University of Vermont. His fatal malady was pneumonia. He leaves a widow and one child.

J. R. LESTER, M.D., of Lebanon, Tenn., February 14.—James Nichols, M.D., of Bradford, Pa., February 16.—S. P. Phillips, M.D., of Ashland, Ohio, February 9, age 41.—A. L. Bronmессette, M.D., of Stafford Springs, Va., February 17.—W. H. Trigg, M.D., of Booneville, Mo., February 21.—C. H. Smith, M.D., of Nyack, N. Y., February 16.—G. S. Comine, M.D., Miller's Falls, Mass., February 19.—O. H. Menees, M.D., of Nashville, Tenn., February 17.—H. L. N. Dubois, M.D., of Portsmouth, N. H., February 24.—M. D. Gordon, M.D., of Huey, Ill., February 23.

## SELECTIONS.

**Etiology of Endometritis in Pregnancy.**—A writer in the *Weiner Klinische Rundschau* had previously at Berlin reported two cases of endometritis of the decidua, in which he had succeeded in demonstrating in the decidua numerous diplococci, at times plainly intracellular, but at that time no cultures were attempted. Recently one of these two patients again came under his observation at the Policlinic of Professor Veit. The decidua area was thickened to two and one-half to three cm., intensely yellow and still remained *in situ*. Histologically the process appeared chiefly as a small-celled infiltration. Among these cells were found a multitude of bacilli, at times joined in longer strings, which were cultivated on agar-agar and gelatin. These bacilli are small rods, rounded at both ends, and of moderate thickness; they show a great similarity to the bacterium coli commune, but are distinguished from it by their behavior under Gram's method. On account of the circumstance that the demonstration of these microorganisms occurred twice in the same patient, the writer believes that he can ascribe to them a prominent rôle in the etiology of endometritis.

**Peri- and Para-Metritis.**—In the *Centralblatt für Gynäkologie* a compilation has been made from forty-four cases of all

those inflammatory processes of the uterus and its appendages which so frequently result from childbirth, abortion or gonorrhea. Several cases of salpingitis may have been included on account of difficulty of diagnosis. In old exudates a mere puncture was generally sufficient; in acute processes with rapid collection of pus a more extended incision, many times also drainage. Of the forty-four cases thirty-four recovered, nine were improved and one died of tuberculosis of uterus and peritonitis, twenty-three were incised, nineteen punctured, and twice there was spontaneous rupture into the vagina. The contents were generally pus, at times a bloody serum or clear serum. The quantity varied from one c.c. to one liter. Length of treatment four days to five months.

**Tuberculosis of Iris.**—Dr. Hans Adler has exhibited a case of tuberculosis of the right iris in a young woman. This affection, he states, is marked by a number of grayish-white nodules, from the size of a poppy seed to that of millet, which lie principally in the ligamentum pectinatum. This condition may be differentiated from gummata in that the nodules are grayish-red in the latter, while sarcoma is not multiple. The history will usually aid in diagnosis.—*Wein. Klin. Rundschau*.

## MISCELLANY.

**Seasonable.**—*Les Nouveaux Remèdes* offers the following seasonable suggestion of an application for chilblains: Tincture of digitalis, 6 grams; thymol, 3 grams; alcohol, 150 grams; glycerin, 150 grams. Mix. To be rubbed on the affected part.

**Bellevue Hospital College Alumni.**—A newly organized alumni association of the Bellevue Hospital Medical College, on February 20, held its first anniversary meeting and banquet, under the presidency of Dr. George A. Evans. At an election then held Dr. R. M. Wyckoff was chosen to succeed Dr. Evans as President for 1895-96.

**Requests for Portland Charities.**—The will of the late Ira Farrington, of Portland, Me., gives sums varying from \$2,000 to \$40,000 to certain named public charities. Of the residuary estate, the two-thirds part goes to the Maine Eye and Ear Infirmary at Portland, while the remaining third is devised to the Public Library.

**The Doctor in Fiction.**—The *Lancet* is fond of quoting the favorable views that writers of fiction are pleased, at times, to take concerning the profession of medicine. The following is one such view, appearing in an American serial publication recently: "Our doctors have to live, of course, but they are kind-hearted as a rule, and take more interest in setting their patients on their feet than in pursuing people for their pay."

**Hippopyrrhin.**—Dr. Badour, of Palaiseau, a retired French army surgeon, suggests "hippopyrrhin" as an appropriate name for the diphtheria antitoxin—compounding the word from ἵππος, a horse, and πυρρὸς red, in recognition of the equine and of Dr. Roux (*roux*, red). This may be, as the *British Medical Journal* says, a dainty device of philological ingenuity, in which "is enshrined a double-barreled compliment." But has Dr. Badour taken into the account one Behring of Berlin, who seems to have some claim to recognition in the distribution of prenominal compliments?

**New York Bacteriologic Bureau.**—One of the recent appointees at the New York Health Board's laboratory for the production of the antitoxin of diphtheria is Dr. Anna Williams. She is a medical graduate, and an assistant in the pathologic laboratory of the New York Medical College for Women. Having early taken a predilection for research in

pathology, she took special courses at Leipsic, and elsewhere in Germany, in lines that have fortunately fitted her for advanced bacterioscopic work. She was admitted to study in the bacteriologic bureau of the Board of Health after a careful examination, during which she readily demonstrated a marked ability in the identification of bacteria. Dr. Williams was one of the first of the eligible candidates to be proposed for a place in the Bureau of Dr. Biggs, when it was determined to increase the staff for the purposes of producing the new antitoxin. Her age is quoted at 25 years. The moderate salary of \$100 per month is allowed for her expert services.

**Malakin as an Antipyretic and Antirheumatic.**—Dr. Robert Abernethy is strongly impressed with the results of malakin in cases of pyrexia of rheumatic and other origin. He details (*Edinburgh Medical Journal* February, 1895) a striking instance of frequent, aggravated, pyrexial outbursts in a case of acute rheumatism, promptly relieved by 15 grain doses of malakin thrice daily, after more than three months of unsuccessful routine with salicin, sulphate of quinin, ice-packs, etc. He has since given it, after other antipyretics had failed, in a good many cases of pyrexia due to various causes; among others, a case of rheumatic fever, with advanced mitral disease, in which it controlled the symptoms admirably without apparently causing any considerable depression; also in two cases of croupous pneumonia in children of 9 and 11 respectively, in which it seemed to have a beneficial effect, both making remarkably good and speedy recoveries. [See also this JOURNAL for February 9.]

**Physical Degeneracy in Prostitutes.**—In his "Etiology of Osseous Deformities," Dr. E. S. Talbot traces the association of physical degeneration with the criminal classes and has made some interesting observations on the anomalies found in prostitutes, showing that these women are a class in themselves, presenting marks of arrest of development and physical and mental degeneracy. The cases examined were not selected, but were taken as they occurred in hospital from those not disfigured by syphilis. In 150 prostitutes thus examined the following abnormalities were noted:

Malformation of the head . . . . .	62
Development of occipital protuberance . . . . .	62
Very receding forehead . . . . .	18
Hydrocephalic . . . . .	15
Various anomalies of the face, prognathism, etc. . . . .	64
Ogival palatine vault . . . . .	38
Congenital division of palate . . . . .	14
Vicious implantation of teeth . . . . .	62
Hutchinson's and Parrott's teeth . . . . .	19
Absence of lateral incisors . . . . .	10
Badly margined ears (Morel) . . . . .	16
Defective ears, deformed, etc. . . . .	47
Anomalies of extremities . . . . .	8
Local asphyxia . . . . .	2

The comparison of these cases with educated women and illiterate peasants is interesting; 82 per cent. of the prostitutes present more than a single anomaly, while among educated women there is found only 2 per cent., and in the peasant class 14 per cent.

**Liquor Potassae in Chloral Poisoning.**—In a brief paper in the *Glasgow Medical Journal* (February, 1895), Dr. John Dougall points out that whatever facts or theories there may be regarding the *modus operandi* of the hypnotic and anesthetic action of chloral, there can be no doubt about its chemie composition and affinities, and, in particular, that it is almost at once decomposed, at and above 60 degrees F., outside the body, by an alcoholic solution of KHO, and, somewhat less quickly, by an aqueous solution of the alkali. Therefore, assuming that a person has swallowed a poisonous dose of chloral—say 80 grains, as was done inadvertently by the late lamented Professor Tyndall—and that there could with safety be given, as a chemie antidote, 27 grains of KHO—this amount being the quantity by weight required to decompose 80 grains of chloral, there are strong

*a priori* grounds for assuming that in about fifteen minutes the chloral in his system would be entirely changed into formate of potassium and chloroform, or at least, that so much of it would be decomposed that the residue would be harmless. As a matter of practice Dr. Dougall would give, in such a case as Professor Tyndall's, 220 minims of liquor potassae—equal to 14 grains of KHO—highly diluted in warm milk, gruel or barley water, in two doses, an hour apart. If this were given before the patient was too far gone the amount of chloral in the system would soon be reduced to a quantity quite within the bounds of safety for an adult, providing there is no heart trouble.

**The Army Medical School, Netley, England.**—The sixty-ninth session of this school was brought to a close on January 31, when twelve surgeons on probation were successful in passing the examination for the British, and fourteen for the Indian Medical Service. The address to the young officers was delivered by W. H. Russell, LL.D., the veteran war correspondent of the *London Times*, who achieved prominence in the literary world during the Crimean War and who has since accompanied troops in no fewer than nine campaigns. He referred at length to the difficulties experienced in the Crimea by the Medical Department of the Army, mentioning the names of many medical officers who were crushed under a weight of obloquy for what they could not help. They could not make bricks without straw. They could not save the lives of those who were perishing with hunger, cold, want of medicine, clothing and everything needful to keep them alive. At that time the Medical Department was not responsible for the arrangements for the cure of the sick and wounded. Now, all this is changed. He complimented the Director General, Sir William McKinnon, the Indian veteran, Sir Joseph Fayrer, and Sir Thomas Longmore, the only survivor of those present at the inauguration of the Army Medical School by Sidney Herbert in 1860. Surgeon-General Maclean also addressed the young officers wishing them a successful, happy, honorable and useful career.

**Observations on Tertiary Syphilis.**—In a paper read before the Fourth German Dermatological Congress, Ehlers, of Copenhagen, presented statistics of 6,816 cases of syphilis under treatment from 1864 to 1881 in the Communal Hospital of Copenhagen. In the résumé given in *Ann. de Derm. et Syph.* these statistics show that tertiary lesions are more common in the first four years. As regards the infectiousness of tertiary phenomena Ehlers thinks that we must revise our opinions. Gummata of the genital organs are especially suspicious, and he cites a case: Patient infected and treated for three years; married; two healthy children were born and his wife was not infected; eight years after the infection the patient had an ulcerating gumma on the penis, which healed badly; two weeks later his wife had a maculo-papular eruption. Ehlers makes the following summary of his observations: 1. Tertiary symptoms were observed in from 12.4 to 22 per cent. of all syphilitics treated in the hospital. 2. Tertiary as well as secondary symptoms are 10 per cent. more frequent in the male; females are not so subject to tertiary symptoms. 3. Tertiary lesions are observed principally on the skin—1,385 times on the skin alone, 139 times on skin and bone; next come ulcerative and destructive processes of the tongue, palate, nose, air-passages—390 cases; in the third place come the nervous lesions—261 cases—which are, in reality, by far the most frequent, but often escape the notice of the syphilographer; if there be added to this group, tabes dorsalis, general paralysis and syphilitic encephalopathy the number of nervous lesions will be increased to 463; lesions of connective tissue occupy the fourth place in point of frequency; the frequency of syphilis in the internal organs can not be determined. 4. The most common cause of tertiary manifestations

### ANTI-TUBERCLE SERUM.

THE TREATMENT OF CONSUMPTION BY SEROTHERAPY—  
REPORT AND PRESENTATION OF CASES TREATED—  
EXHIBITION OF SERUM, ETC.

Read before the St. Louis Medical Society.

BY PAUL PAQUIN, M.D.  
ST. LOUIS, MO.

*Preliminary Remarks.*—It would seem superfluous to say a word here on the pathology of this affection. But the nature of the new treatment demands that we refresh our memory on some points of it before certain therapeutic questions to be dealt with presently may appear clear. The result of my observations and researches have convinced me beyond a doubt that tuberculosis, in the stage of lesions, particularly when pulmonary cavities, intestinal ulcers, etc., exist becomes a mixed infection, due to the introduction of various other pathogenic microbes besides the bacillus of tuberculosis in the specific wound. Myriads of germs of the air, water and food gain access to tuberculous lesions and complicate the primary disease to a very grave degree. The destruction of tissue by these germs, the production of new mixed poisons, perhaps more dangerous sometimes because of chemic combinations, are largely responsible for the irregular chills, fevers and some other pathognomonic phenomena to be seen in advanced tuberculosis. These complicated microbic disturbances which so greatly depress and harass the system are, perhaps, assisted in their nefarious work by the toxins generated in a weakened impaired digestive tube which, failing to digest the food properly, leaves it the prey of various toxic-ferment manufacturing microbes. It is well to bear these points in mind when considering the anti-tubercle serum as a therapeutic agent in tuberculosis, for it probably will not improve complicated cases.

On the other hand, in tuberculosis we should never lose sight of the natural vital resistance of the exposed or suffering individual. It is this *vital resistance* of nature that saves the minority who escape all the damaging influences of the disease, and the principles underlying it explain the serum therapy. To understand this vital resistance, its nature and its scope and increase it in medical practice, is to wield a powerful weapon against the foe. The cursory method of diagnosis, therefore, merely by the interpretation of physical signs is not sufficient to put the doctor in possession of all the important facts necessary for an accurate interpretation of tuberculous phenomena and the proper treatment. The microscope should be brought into play early and often, not only to discover the existence or absence of the bacillus of tuberculosis, but also to establish the differential nature and stage of the organic

lesions as far as possible and to realize the nature and extent of the mixed infection when it exists.

### SEROTHERAPY IN TUBERCULOSIS.

I began the serious study of tuberculosis and experimentation in 1888, at the University of the State of Missouri at Columbia. During my service at that institution I had unsurpassed opportunities for studies in comparative pathology and experimentation. Early in my researches on tuberculosis, I became convinced that the equine species is, to a certain degree at least, naturally immune to the disease, the ass being less susceptible, possibly, than the horse, although I am by no means convinced of this. Later, following step by step the work of Metschnikoff on the theory of phagocytosis, Kitasato and others on the antiseptic properties of blood serum, I formed the conclusion that the chief and direct basis of immunity was lodged in the blood. When the Japanese scientist just mentioned and others, published that properly immunized blood serum was efficacious in the treatment of tetanus, revealing by this momentous discovery the great secret of nature's force in resisting this disease, the light began to dawn in my mind, as in that of every medical man doubtless, to the effect that the prevention and cure of contagions by the use of nature's own remedy was only a question of time. Not many years after, came the welcome announcement that diphtheria was curable by the use of a specially immunized blood serum. The press also reports that investigators in Switzerland and France are testing the blood serum of the ass. Now, I beg to report that by the same principle which underlies the antitoxic serum of Kitasato for tetanus, of Behring and Roux for diphtheria, horse blood serum may be rendered more antagonistic to tuberculosis than it is naturally. This I have accomplished, in laboratory experiments and the result obtained in treating consumptives in the first and second stages, and some in the third stage, indicates quite pointedly that serotherapy will perhaps master this dreadful plague. Indeed, I dared not hope for such universal improvements as were obtained. While in advanced consumption with cavities or other serious lesions impairing important organs gravely, I have not yet arrived at a point where I may formulate reliable deductions, a large per cent. of such cases very seriously involved, increased in six to eight weeks from five to sixteen pounds in weight without any tonic, and without any specially reconstructive diet, only the regular city hospital or poor house fare being admitted, certainly not over nutritious, whereas every witness case in the same ward, suffering with the disease in practically the same stages, untreated by blood serum continued to decline steadily or failed of improvement. Furthermore, the treated

NOTE.—The scientific experiments carried on then and since, both in the laboratory and the field, will form the subject of a special paper. This will contain explanations and results as per records kept.

cases soon began to sleep better, to cough less, expectorate less, eat with relish and their night sweats diminished. In a couple of instances in the first and second stage, cough and expectoration ceased entirely in less than eight weeks, while all the general signs of good health reappeared. There is scarcely enough expectoration in these to make microscopic analyses, and the germs are no longer to be found. I have also several cases with large cavities which have improved remarkably. I have brought here to show you, some of the worst which we have under treatment, that you may judge for yourself of the nature of the affection and its lesions. These had cases with marked alterations of the lung tissue have gained in weight, a number of pounds in eight weeks and have improved in every way. Two of these were stretcher patients when brought to the city hospital. Both had been condemned as hopeless by several physicians. One of these weighs now more than he ever did at his best, when he was perfectly sound and healthy. We have not had any case of any kind under treatment longer than eight weeks, and obviously it is too early for me to express unqualified conclusions, particularly on the serious conditions which to be cured, demand that nature shall build new tissues to fill the gaps. But that serotherapy will prove eventually efficacious to arrest consumption, I feel almost assured.

None of the improvements can be ascribed to mental influences, as it was in nearly every case against the will of the patients that we injected them. For four weeks or more they fought and objected, and only after realizing themselves the benefits did they submit gracefully.

These results surely point to good grounds to hope for more success. Indeed, if in such a short time under such circumstances and in such surroundings one can put flesh and fat on a consumptive, while untreated witness cases under the same conditions continually fail, or at best hold their own, what may we not hope if consumptives in the first and second stages, at least, are placed in a modern sanitarium, or kept in their homes even and surrounded by all the cares and necessities for the rich reconstructive diet that should be granted such unfortunates? What may we not expect if we give them, furthermore, all the sanitary conditions that may aid nature to cure or arrest tuberculosis in any event?

#### RECORD OF CASES.<sup>2</sup>

Mike Morley, age 53, pulmonary tuberculosis in the second stage, has been ill seven years; family with history of tuberculosis. Left lung affected below the scapula at the back; dullness of the apex. Circumference of the chest in expiration 36, inspiration 37.5 inches. Coughed seriously and considerably. Expectoration was yellowish, blood tinged, sometimes pure blood. Bacilli of tuberculosis numerous. Began treatment Dec. 1, 1894. Weight 165 pounds. Lung vital capacity, 110 cubic inches of air. January 26, weight 170 pounds, an increase of 5 pounds in fifty-seven days. Lung vital capacity 110 cubic inches of air.

Charles Reck, age 48, began treatment Nov. 30, 1894; discharged January 3. Was brought to City Hospital on a stretcher; could barely rise on his chair to eat. During thirty-six days' treatment gained nineteen pounds. This man had tuberculosis of the lungs in the third stage;<sup>3</sup> duration two years. Bacilli of tuberculosis profuse; cavity in the left infra-clavicular space; expectorated a considerable amount of blood and sputum.

Phil Hye, age 35, pulmonary tuberculosis, second stage. Coughed six years; was very emaciated; had dullness and softening in one or both apices. Chest during expiration

thirty inches; inspiration thirty-one. Tubercle germs present in abundance. Coughed constantly night and day; mucopurulent expectoration. Began treatment December 1; weight eighty-one pounds; was sleepless. January 26, weight eighty-nine pounds, a gain of eight pounds in less than eight weeks. Cough disappeared almost entirely; sleeps well. This patient was very weak on entering the City Hospital. He had been sent here from Texas, having been given up as hopeless, he said, by Dr. Jestus, city physician of El Paso, Texas, and Dr. Menger, of San Antonio, Texas. He was sent home to die, being considered hopeless. He stated that he had also been condemned as hopeless by a physician of Alexian Brothers Hospital of Chicago, where he had been under Koch's treatment. This patient is now around and about. He walked several blocks from the street cars to come to the meeting of the medical association, in the raw evening atmosphere and in muddy snow. He coughs little or none.

George Dobson, age 28 years, seriously ill two months previous to treatment; pulmonary tuberculosis in the second stage; had had hemorrhages occasionally; had dullness in right apex in infra-clavicular region; expectoration scant. Began treatment December 1; weight at that time 107 pounds; weight January 26, 117.5 pounds, a gain of 10.5 pounds in eight weeks. Vital capacity at the beginning of treatment, 100 cubic inches; vital capacity January 26, 150 cubic inches, a gain of 50 cubic inches.

John Smith, age 23, pulmonary tuberculosis, third stage; duration two years; mother had died of consumption. Lost thirty pounds in two years; affection below the left apex; large cavity; coughed particularly in the morning. Weight December 1, 145 pounds; vital capacity 170 cubic inches. Weight January 26, 154 pounds, a gain of 9 pounds in eight weeks. Vital capacity 180 cubic inches, a gain of 10 cubic inches.

Otto Maye, age 58, pulmonary tuberculosis. Had been suffering for several years. Appetite very poor; coughed considerably; had had slight hemorrhages several times in the morning. Bacilli of tuberculosis present. Weight at the beginning of treatment December 1, 135 pounds; lost flesh gradually until he reached 131 pounds on January 1. Is now gaining and has gained two and one-half pounds between January 1 and January 26. Vital capacity at the beginning of treatment 110 cubic inches, January 26, 160 cubic inches, a gain of 50 cubic inches. This patient is one of those that had an abscess during the process of treatment. He is now gaining.

Nicholas Robinson, age 61; pulmonary consumption in second stage; duration two and a half years. His mother died of consumption. Had had several hemorrhages; night sweats; coughed seriously at nights; expectoration considerable; specific germs present. Affection is in the infra- and supra-clavicular regions, both sides; dullness was quite marked; softening on one side. Weight at the beginning of treatment 119 pounds; weight January 26, 131 pounds. Has gained twelve pounds in about or less than two months. Vital capacity 150 cubic inches, December 1. Vital capacity January 26, 180 inches, a gain of 30 cubic inches. This patient was very weak; could not speak when he was brought to the hospital. He was given up as hopeless. Mild laryngeal tuberculosis existed. Was sleepless. Now sleeps well; coughs very little, has a good appetite and feels stronger.

John Cummings, age 49 years. Weight 90 pounds December 1; weight January 26, 106 pounds, a gain of 16 pounds in two months. Vital capacity December 1, 100. Vital capacity January 26, 110, a gain of 10 inches. This man had had frequent hemorrhages during last summer, and before that, and was almost bed fast. He was very emaciated. The bones almost protruded as a nurse expressed it. The bacilli numerous. The nurse was afraid of bed sores. Appetite was lost, coughed and expectorated a great deal; in fact, the case was despaired of. Is now improving continually, is up and about and able to go up and down stairs and feels in every way in better health; weighs one pound more than in his best health.

John Broderick, age 24; pulmonary tuberculosis in the third stage, duration over one year. Brother died of quick consumption; was very weak, emaciated, had a cavity in left infra-clavicular region, coughed continuously for two months previous to treatment. Weight December 1, 105.5 pounds. Weight January 26, 113 pounds, a gain of 7.5 pounds. Vital capacity 100 cubic inches before treatment. Vital capacity since, varied between 110 and 130 up to Jan. 26, 1895. This is one of the two cases that had an abscess in the back. He was almost bed fast when treatment began. Coughed a great deal night and day. Was very weak;

<sup>2</sup> While preparations for treatment began the last days of November, regular injections began on or the day before December 1.

<sup>3</sup> Diagnosis of city physicians.

breathing was very short and labored. Now coughs very little. No more pains or distress. Is up and about and on detail duty.

Henry Riley, age 34. Weight beginning of treatment 115 pounds. Weight January 26, 124 pounds, a gain of 9 pounds in two months. Had pulmonary consumption in the second stage; duration one and one-half years. Tuberculosis in the family. Had night sweats, diarrhea, marked dullness in the right supra- and infra-clavicular region; appetite poor; coughed frequently at night; expectoration considerable. He was a very sick man, indeed, but is now improving rapidly, and is in fact on detail duty.

James McCafferty, age 48, pulmonary consumption, second stage; duration of cough several years; serious illness in last five weeks; spit blood five weeks previous to treatment; frequent diarrhea; dullness left supra- and infra-clavicular region. Weight at beginning of treatment Dec. 1, 106.5 pounds. Weight January 26, 129.5 pounds, a gain of 13.5 pounds in eight weeks. Vital capacity at the beginning 130 cubic inches of air. Vital capacity January 25, 160 cubic inches, a gain of 30 inches. Was a very sick man, unable to do anything. Is now on night duty at City Hospital, works from 11 P.M. to 6 A.M., a very trying duty for a tuberculous patient.

Thos. Morrison, age 42; pulmonary tuberculosis, second stage, duration over three years; had hemorrhages in 1891. Cavity in left apex. Pronounced dullness in right infra-clavicular region; tubular breathing over same region; appetite poor; cough and expectoration pronounced. Has been in the City Hospital for a couple of years. Weight at beginning of treatment, December 1, 156 pounds. Weight January 26, 158 pounds, a gain of 2 pounds. Vital capacity at the beginning of treatment 160 cubic inches. Vital capacity January 26, 170 cubic inches, a gain of 10 inches. This case does not improve as rapidly as others in worse condition.

John Hopkins, age 48; pulmonary tuberculosis advanced first stage, two years' duration. Mother died of consumption. Digestion bad; cough was getting continually worse; had lost much flesh. Weight Dec. 1, at beginning of treatment, 137.5 pounds. Weight January 26, 144 pounds, a gain of 6.5 pounds in about eight weeks. Vital capacity at the beginning of treatment 250 cubic inches. Vital capacity increased between then and now (January 26) to 260 and even 270 inches.

Conrad Hogan, age 32, pulmonary tuberculosis in second stage; family history good; had slight hemorrhages, night sweats; getting weaker daily; right apex involved and dull; coughed considerably. Weight at the beginning of treatment December 1, 135 pounds; weight January 26, 142 pounds, a gain of 7 pounds in those eight weeks. Vital capacity at the beginning of treatment December 1, 180 cubic inches. Vital capacity January 26, 200 cubic inches, an increase of 20 inches.

Henry Willer, age 46; pulmonary consumption, third stage; no family history of consumption; both apices involved; had had hemorrhages; had been ill five years. His disease had begun with pneumonia. Vital capacity at beginning of treatment 140 cubic inches. Vital capacity to-day is the same. Weight December, 133 pounds. Weight January 26, 132.5 pounds, loss of a half pound. This patient has not increased in weight but has declined less than previously and is stronger and better generally. Temperature is normal and he expresses himself as gaining. It is not a favorable case.

Nils Johnson, age 34; pulmonary tuberculosis third stage. Duration twenty months; dullness on percussion of the apices; tubular breathing; hemorrhage a year ago; expectoration not very pronounced. Weight December 1, at beginning of treatment was not reported. January 1, 156 pounds; January 24, 158 pounds, a gain of 2 pounds in twenty-four days. This patient is not a favorable case; has variable temperature and chills occasionally. It seems to be a mixed infection.

Nicholas Schappo, age 56; pulmonary tuberculosis, second stage, two years' duration; night sweats; left apex dull; coughed considerably at night, and expectorated very much; bacilli of tuberculosis in great numbers. Weight December 1, beginning of treatment 108 pounds. Weight January 26, 107 pounds, loss of 1 pound. Vital capacity December 1, 140 cubic inches. January 26, 150 cubic inches, a gain of 10 inches. This man is ageing and broken down generally and is not a favorable case although he more than holds his own. He has now stopped declining and I may say his lung capacity is better.

Conrad Opperman, age 47; pulmonary tuberculosis in the third stage, duration six months. Mother died of consump-

tion; has had night sweats; was exceedingly emaciated and very weak. Cavity in the right infra-clavicular region. Has diabetes (diagnosis of Dr. Ehrlich); coughed in the morning considerably; bacilli very numerous. Weight at the beginning of treatment December 1, seventy-nine pounds. Weight January 26, eighty-two pounds, a gain of three pounds against continual loss before. Vital capacity at beginning of treatment fifty cubic inches. Has varied since then between fifty and seventy. This man was a stretcher case, brought to the hospital helpless. Could not get up the steps for a long time. Even after some treatment he was very thin. Is now improved, coughs little and is in better health in spite of his diabetes or glycosuric condition. Bacilli much decreased in quantity.

Fritz Arnold, age 59; pulmonary tuberculosis, second stage, duration two years. Tuberculosis in the family; coughed persistently; expectoration profuse; bacilli numerous; appetite bad. Weight at the beginning of treatment, December 1, 122 pounds. Weight January 26, 127 pounds, a gain of 5 pounds in eight weeks. Lung capacity December 1, seventy cubic inches. Vital capacity since has varied between 80 and 110. This is a broken-down constitution generally, but has improved in spite of it. Bacilli now scarce.

William Murray, age 41; pulmonary tuberculosis second stage, duration one year; family history good; is a drinking man; consolidation right apex; night sweats; blood in sputum; appetite poor; coughed a great deal; bacilli very numerous; expectoration profuse. Weight Dec. 1, 1894, 132 pounds. Weight January 25, 134.5 pounds, a gain of 2.5 pounds. Vital capacity at beginning of treatment seventy cubic inches. Vital capacity January 26, 120 cubic inches, an increase of 50 cubic inches.

Thos. Bennett, age 64; pulmonary tuberculosis, second stage; been coughing four months; very emaciated; affected with long standing gastritis; right supra-clavicular region involved, dull. Lung emphysematous; appetite poor; coughing considerable; sputum tinged with blood sometimes and contained bacilli of tuberculosis. Weight December 1, at beginning of treatment, 125 pounds. Weight January 26, 130 pounds, a gain of 5 pounds. Vital capacity keeps 110 cubic inches.

Martin Lemp, age unrecorded; tuberculosis first stage; bacilli numerous. Weight at beginning of treatment December 1, 131.5 pounds. Weight when discharged January 10, 151, making an increase of 19.5 pounds. Lung capacity increased from 170 at the beginning to 190 when discharged. This case was treated a little over a month and a half. He had been reduced greatly in strength and flesh, was unable to work and had to leave his family for the City Hospital. Has now returned to work. Have had no chance to examine his sputum since discharge, when no expectoration existed, to investigate the microbic question.

I purposely omit saying anything about the physical symptoms after treatment to date. This is a record to show general improvement to date, particularly to demonstrate that the great prostrating debility of consumptives (the very ground of tuberculosis as some term it) is the first thing to yield seemingly to the effects of serum.

The following are cases treated and reported by Dr. Cale:

*Dear Doctor Paquin:*—I inclose, herewith, reports of the cases of tuberculosis which have been under my care and treated with your immunized blood serum.

*Case 1.*—Charles J. M., aged 23 years; family history good; was in perfect health until seven months ago; since that time has had a cough, fever in afternoon and subnormal temperature in morning, loss of appetite, loss of weight, night sweats, etc. Small cavity in apex of left lung; large amount of expectoration; bacilli found in sputum in large numbers. Date of first treatment Dec. 22, 1894. The case has progressed nicely. Cough much less; expectoration less; no night sweats and gain in weight of three pounds in two weeks. During the last six days has gained two pounds, sleeps well; in fact all the symptoms have improved.

*Case 2.*—W. A. Buckley, nurse at the poor-house, age 33; family history good; attack dates back two years; cough, expectoration; pain in left side at base of lung, where a small dull area was found; loss of appetite and weight; had had night sweats for two months preceding December, 1894. Bacilli in sputum. Treatment during December and two weeks in January. No cough or any bad symptoms since

January 1. Dullness disappeared and gained six pounds in weight. No night sweats; temperature normal; no more expectoration.

*Case 3.*—George Roth, age 63; tuberculosis in third stage; family history good; temperature ranged from 96.5 to 103.5; cough frequent; expectoration; night sweats; no appetite and loss of weight; bacilli present. Treatment seven weeks. No cough. Gain three pounds.

I have treated irregularly, during a few weeks, two or three more cases at the poor-house, but they are insane and the treatment was not done satisfactorily. However, there was some improvement even in some of them.

GEORGE W. CALE, M.D.

All these records were kept accurately by the physician and nurse in charge of the cases at the City Hospital, and by Dr. George W. Cale, the physician who was put in charge of the poor-house cases, whose valuable assistance I secured as soon as I had gained the idea that I was in possession of blood serum truly useful for the purpose intended. Dr. Cale was selected because of his qualifications in microscopy and surgery, accomplishments required in a man whose help was needed to verify the diagnosis of each case microscopically, and to give an

opinion on surgical cases of tuberculosis, which I wished to secure for experiment. The sputum of every case treated, contained the bacilli of tuberculosis. Dr. Cale mounted specimens from each, and he and I examined every one of them. They have been labeled and kept for future reference. At the City Hospital, after the inauguration of the treatment, the immediate supervision of the injections and attendance was by Dr. Ehrlich, who did his duty carefully and conscientiously. Mrs. Johnson, a very competent woman, was in charge as nurse.

Blanks worded as the sample shown were used, blank A being for the daily reports, and blank B for the history, nature, etc., of each case, and the compilation of the daily records at the end of each month. And so, for each case every precaution was taken that seemed necessary to insure reliable records and to convince the medical profession of the truth of the facts reported.

### THE PREPARATION OF THE SERUM AND ITS APPLICATION.

By laboratory processes I gradually rendered horses more strongly refractory to the action of the germ than they are naturally. Immunization was carried on with the assistance of a deputy veterinarian, Dr. Rouif, of this city, who had previously kept the horses under surveillance and had examined and tested them carefully with me, and independently, until we had fully convinced ourselves of their healthfulness.

Having immunized horses and tested the serum by experimental processes, and noted its effects on animals, and having injected it in myself several times, at intervals and at increasing doses to determine its reaction, it became necessary to procure a number of tuberculous patients to test its value in human consumption. With this object in view, I

 The record is correct. \_\_\_\_\_ M.D.

secured from Dr. Homan, Health Commissioner, the permission to select a few cases at the poor-house for treatment, and also secured from Dr. Marks, Superintendent of the City Hospital, leave to try the remedy in this institution. Both of these officers have been very kind. They turned over to me and my colleagues all the cases we wanted and expressed their good will in many ways. I owe them my sincere thanks for their generous assistance and am under obligations to them, as also to the physicians of the poor-house.

The treatment began with injections of 10 drops hypodermically in the back between the shoulder blades. In a few days we increased to 20 drops.

Then to 30, 40 and 60. Some were given as many as 70 drops once a day for awhile. To a few in private practice, I have injected as much as 150 drops at one sitting every day for several days. No reaction whatever followed these injections and the pain is no greater than during the usual injection of a morphin solution. There resulted no accidents whatever from over fifteen hundred injections in the various patients, as a whole, except at the City Hospital where two benign abscesses were produced. They were without doubt due to accidental infection by the syringe, probably the leather ends of the piston of the syringe used at the time, or the needle. Careful disinfection of the syringe will always prevent this occurrence. The serum is, in fact, innocuous, absolutely so, if well prepared.\*

#### PROSPECTS OF SERO-THERAPY.

The future of the serum therapy in several infectious diseases seems assured beyond peradventure. We may have been too enthusiastic and may have expected more than we can now obtain, perhaps, and possibly the great enthusiasts may be painfully disappointed in their hopes for immediate or remote wonders from the sero-therapy in diphtheria, tetanus, etc., but the fact will always remain that this system is unquestionably rational and that eventually, all indicate it must yield success in therapeutics where all else must fail, for it is the one rational, truly physiologic treatment, the only treatment in my humble judgment from which can be derived positive beneficial results in the cure of infections. It is nature's own remedy. Man with the serum is using nature's own weapon of defense; he has found out how he may add power to the natural resources of the organization in the fight for human existence. This system of treatment is not a spontaneous eruption in therapeutics. It is not the explosion of over-zealous laboratory delvers with more enthusiasm than experience; it is the result of years of research in all the laboratories and the chief clinics of the civilized nations, particularly France and Germany. And it is not only yesterday that it appeared in practice. It was several years ago that Kitasato applied his antitoxin experimentally against tetanus. Diphtheria has been treated successfully a year or more. Syphilis is now, it is stated, treated experimentally with it, and lastly your humble servant begs to submit to your indulgent criticism the result of his meager labors, conducted under extreme difficulties, and without State or any outside financial aid. The future of sero-therapy in tuberculosis is, in my mind, very bright and very promising. The first, the second and the third stages of consumption have been benefited under unfavorable circumstances by even slightly immunized serum. Consequently, it is only fair to reason that with more strongly immunized serum, such as I have now ready to use, (I have only a limited quantity) much better and quicker results can be obtained, particularly if proper hygienic and dietetic conditions are obtained. Theoretically, it would seem that, if by the use of this serum constitutionally, the tuberculous processes may be arrested in a given case, injections directly in the pulmonary cavities where these exist, or the excision of a rib or two and the use of tubercle antitoxin directly into the wound, would prove practicable and useful to save life. It would seem, too, that such cases as hip joint

disease, which, according to statistics, is more successfully treated by the expectant therapy than active operation, could be safely operated after the arrest of the tuberculous process for, as Koenig has pointed out, it is the operation that disseminates the bacilli in such cases, so many of which terminate fatally after the usual surgical interference and the usual after treatment. And so in all surgical cases of tuberculosis, whether it invades the bones, the joints, the ovaries, the skin, the tendons or other organs, or several of them, if the serum will, by some means, stay the microbes, as I have every reason to believe it will, there is ground for congratulation on its introduction in therapeutics.

Besides the use in the treatment of tuberculosis, we have a promising means of protection of those exposed, by the practice of periodical injections of antitoxic serum, which may render the susceptible immune, for awhile at least. As a prophylactic the antitoxic serum should prove very useful in the preservation of families tainted by inheritance, or exposed to the germs from their birth.

In closing, allow me to summarize the opinions arrived at after my few years of investigation and observations, and the recent incomplete practical tests of my colleagues and myself.

1. Sero-therapy in tuberculosis has proved, so far, efficacious.

2. Blood serum of horses seems naturally antagonistic to the germs of tuberculosis, but can not in its natural state serve in treatment with much good, as it is too slow and it takes enormous quantities of it too, to produce useful results.

3. Horse blood serum may be rendered more strongly antagonistic to the tubercle germ by the proper treatment of the animals by a proper technique.

4. A horse treated properly three months may yield serum with immunizing power that will probably prove sufficient to arrest consumption in the first stages in three or four months, and sometimes less; and in the second stage in four to six months or a year.

5. Discrimination should be made in the selection of cases, and judgment exercised to exclude from the favorable class all those seriously complicated bacteriologically, certain cases complicated otherwise pathologically, and other patients which practice alone will suggest.

6. Inasmuch as hospitals for consumptives are needed any way, the success has been sufficient already to warrant the hope that in the near future such institutions shall be built on modern principles of hygiene, for the exclusive treatment of tuberculosis. Sero-therapy, with the adjunct treatments promises better success than ever obtained before. I do not designate this serum as a *cure* or a *specific*, but a valuable new remedy.

#### TECHNIQUE.

As to the technical features of the preparation of the anti-tubercle serum, I have little to say at present. The profession realizes that success with the serum therapy depends on accurate and delicate laboratory and experimental manipulations which few are fully equipped to undertake. The preparation of the toxins, the measurement of their potency, the dosage for the realization of various degrees of immunity; and, finally, the inoculations of immune animals and the subsequent tests of the therapeutic value of the serum

\* Since reading this paper we had a harmless rash in a few cases.

extracted, are all questions of great moment, and which necessarily involve special training. Commercialism might, at any moment, by some failure or accident throw discredit on the new treatment, were I to explain fully before advancing my researches to a point where a larger number of improved cases and greater benefits, can be shown the details of procedure in the production of the agent. As yet only a small quantity of serum is on hand—not enough to offer to the profession, having under treatment some thirty cases whom I have promised and wish to inject for some time to come. The production of the serum is costly, and above all it takes months to get the best material. I have reason to believe, however, that it will be possible to shorten the time that has been found necessary to strongly immunize the horses now in use.

### THE EARLY DIAGNOSIS OF CARCINOMA OF THE STOMACH, WITH THE BACTERIOLOGY OF THE STOMACH CONTENTS.

BY FENTON B. TURCK, M.D.

PROFESSOR OF DISEASES OF THE STOMACH AND INTESTINES, POST-GRADUATE MEDICAL SCHOOL; ATTENDING PHYSICIAN TO THE COOK COUNTY HOSPITAL, CHICAGO.

(Continued from page 319.)

After the study of sixteen cases Rosenheim (*Berl. Klin. Woch.*, Dec. 24, 1888) concluded that the chemic insufficiency of the stomach in carcinoma ventriculi is not due to the cancer itself, but to the attending atrophy. He divided the pathologic changes into three stages: inflammatory, interstitial and atrophic; adding that these stages may be present at the same time; and Ewald (*Berl. Klin. Woch.*, Dec. 3, 1888) holds that the disappearance of HCl is not due to carcinoma directly, but is merely a disturbance of the functions of the secretory glands.

The post-mortem changes often veil the pathologic changes, unless well marked and permanent lesions occur. It is best, if possible, to secure specimens during an operation for carcinoma of the stomach as far remote from the tumor as possible. In three operations I secured several sections—one for carcinoma planum (anterior wall) where a large area was removed, leaving a border of tissue not infiltrated by cells from the carcinoma; the other two were carcinoma of the pylorus. The sections were cut with a Valentine knife in the fresh state and placed on a slide; 50 per cent. solution of glycerin with a little oil of cloves prevents the change.

A solution after stain in 50 per cent. glycerin is used, for staining, and "irrigated" through according to the old method of Beale. (For making permanent mounts Price's pure glycerin is carried under the cover glass and ringed with cement.) There appears the pathologic changes of inflammation. No distinction between parietal cells and chief cells; cells loosened from their membrane; karyokinesis were illustrated; nucleus crowded to one side; gland cells swollen, closing the lumen; nucleus forced to one side; cells of the mouth and neck crowded together as in proliferation, and lying within the lumen; at other points cystic degeneration, mucoid metamorphosis of pathogenic cells, as shown by Ewald and Boas; leucocytes fill up about the neck and through to the surface of the gland; other points show marked interstitial changes; multiplication of

round cells; vessels engorged flush up to the surface of the mucous membrane, where a rich anastomosis occurs at the mouth and neck of glands. If it is not alone the product formed in the growth of carcinoma of the stomach that causes this inflammatory and rapid destructive process through the infection from growing pathologic and so-called non-pathologic microorganisms colonizing upon the surface of the mucous membrane offers a possible explanation of these changes. Within the lumen of the stomach all forms of germs find their way:

The master work of Miller ("Microorganisms of the Human Mouth," 1890,) has proved that the mouth may become an ideal incubator for at least twenty-five varieties. The nose and pharynx may become an excellent bed for colonization upon the walls. Food and water are by no means aseptic—if we prepare the stomach walls so that colonization may also exist, we have a process set up in proportion to the character of the colonies found—the culture bed and conditions present. In the healthy state the stomach does not seem to encourage colonization in the bed of mucus upon its walls, although germs find their way into its lumen. This will be brought out in another work in relation to gastritis. The predisposing cause seems to be the growing carcinoma—lessening resistance and furnishing a soil,—the inflammatory process, the result of the toxins of the colonizing microorganisms. Well-known pathologic germs produce their special toxins and even the lactic acid bacillus, as shown by Wurtz and Lindet (*La Semaine Med.* Paris, Sept. 9, 1892) produce in animals marked symptoms of diarrhea, distension of the abdomen and extremely rapid emaciation. They learned that cultures in bouillon are very active—toxin is formed having the same effect as the culture itself.

Through the kindness of Dr. Ryan, Louis S., age 40, Italian, was referred to my clinic November 27, complaining of "pain in his stomach and back." No specific history. Family history negative. Experienced no difficulty until within nine months, when there appeared a distress after eating. Appetite remained good; insomnia at times and dyspnea at night. No vomiting. Alternating constipation and diarrhea.

Examination: Skin dry; some evidence of emaciation; mouth, gums inflamed at borders; tongue, light yellowish coat; nose and throat showed no marked lesions; chest organs intact; abdomen, muscles well developed; liver and splenic area normal; stomach, percussion shows slight distension; half moon space of Traube slightly increased; prevailing sound in stomach demonstrated the great curvature one and one-half inches above the umbilicus; no palpable tumor; colon dilated; tympanitis controlled with water and air gave the same results; rectum negative; genito-urinary organs negative.

Analysis of stomach contents two hours after ordinary meal: HCl+; total acidity, 40; Uffelmann's +; blood count 4,800,000. November 27, hemoglobin, 70; fasting stomach twelve hours after meal; reaction neutral. No remnants of previous meal; no stagnation.

Bacteriologic: Six slides stained for microorganisms, after removing mucus from them and mucous membrane with gyromele, four fresh slides unstained. A fine network of long rods appearing like mycelia but more angular. Short rods; colonies in groups attached, end to end and in pairs; streptococci in twisted chains; groups of micrococci; a few yeast germs but no socius ventriculi appeared in the field.

Bacteriologic cultures: Stroke culture on sterilized mucous membrane of the stomach of a pig; first stroke line colonies run together; second stroke more separated, especially at side of furrow of the line; pink colonies; grayish colonies spreading; yellow colonies; brown and a few black colonies raised;

as many as ten or twelve different colonies present. On separating out into tubes the short rods seemed more curved and the threads appeared changed. The long slender rods that formed a thick network and a luxuriant growth on the mucous membrane died out in the tubes. The pyogenic germs appeared, as well as bacilli coli communi. Five colonies were lactic acid forming bacilli.

Tube cultures taken direct from the stomach wall: Tube No. 1, left in stomach juice; No. 2, milk (sterilized); No. 3, bouillon made from stomach of pigs; No. 4, same as No. 3 with starch added; No. 5, plain bouillon; No. 6, same as No. 5, starch added. All placed in incubator at 36 C. for twenty hours.

Reaction: All acid reaction except bouillon culture No. 5. Nos. 2 and 4 showed lactic acid. No. 4 was especially marked. The fluid was filtered and extracted with ether evaporated which gave a fair iodoform emulsion. No quantitative estimation made. December 6, ordered meal soup according to Boas method. December 7, withdrew and analyzed. Lactic acid, 85 per cent.

December 15, entered hospital of the Post-Graduate Medical School; oatmeal soup of Boas at night. December 16, withdrew stomach contents. Analyzed by Dr. Wisner showed lactic acid, 75 per cent. Operation ordered; stomach washed out and December 17 I performed laparotomy, assisted by Dr. Beck, and found a scirrhus carcinoma, two nodules at pylorus; one anterior and one posterior tumor, extending from the end of the lesser curvature. Gastro-enterostomy with Murphy button. Patient was attacked with violent hicough and vomiting; stomach cleaned and fed per rectum; temperature remained normal. December 24, patient died. Post-mortem refused.

July 10, 1894, Mr. F. K., age 53, German, was referred to my office as a stomach case. Complained of pain over xiphoid appendix through to the back. Began to vomit about a year before; had to live on liquid food; dysphagia. Examination: Emaciated; could not pass stomach tube, attempted to pass the revolving sponge but met resistance at the cardiac opening; by using smaller sponges tried to explore the stricture. The cable and spiral within the sponge being more flexible than the ordinary sound there was less fear of puncture. Found a diverticulum containing remnants of undigested food; sputa negative; no albumen or sugar in urine but indican increased. Diagnosis: Carcinoma of the cardiac.

On July 23 gastrostomy was performed by Dr. Newman and myself. Introduced the gyromele through the stomach opening dilated, and passed a rubber tube through the stricture to the mouth. Examination of stomach contents, reaction neutral. July 24, made slides but no cultures were carried out. Slides showed many varieties of long and short rods, especially spirilla. After a gruel injection a slight Uffelman reaction, but not marked. July 28, patient died. No post-mortem allowed.

August 22, 1894, Mrs. S. G. S., widow, aged 65, referred, complaining of distress and burning sensation in stomach after eating. I was told that if carcinoma was thought to be present an operation would be allowed. It is often more difficult to exclude than include. The history, symptoms and general appearance favored carcinoma. Within one year loss of appetite and weight, progressive anemia, morning headache, constipation, belching after eating. Physical examination: Hair dry and brittle; skin dry; panniculus adiposus absent; color, pale, ashy hue. Teeth in good repair; tongue silver gray coat; depression of teeth. Nose and throat atrophic; rhino-pharyngitis; slight discharge from the vault. Lungs negative. Heart, faint mitral murmur. Liver palpable below costal arch. Abdomen retracted. Stomach gastroptosis; transverse colon upper border below umbilical line; prolapse of right kidney, second degree.

August 23, withdrew contents after Ewald's test meal. Litmus +; no HCl; Uffelman's +; peptone weak; urine contained no albumen, blood or sugar 4,560,000; hemoglobin 55. August 28, four hours after meal, stomach was empty; weak acid reaction. August 30, after Boas' test meal, Uffelman's reaction very weak. No iodoform, showing practically no lactic acid. September 1, bacteriologic: Removal by the revolving sponge of mucus thick and tenacious. Slides show the mucus contains cells of the glands, columnar, round cells, leucocytes, also flat cells, a large number of colonies of rods and micrococci. Tube cultures showed many gas forming germs to be present.

A diagnosis made of gastritis chronica, with beginning atrophy and the complications named. Patient put under a vigorous treatment. Stomach walls cleaned with liquid soap, using the gyromele; oil of cloves and cinnamon ap-

plied. HCl exhibited in large repeated doses, as recommended by Ewald. A selected diet ordered, baths and massage.

September 9, recorded that the headache disappeared, the distress in stomach lessened, with but little belching of gas. September 18 recorded appetite much improved. October 29, disappearance of all symptoms. November 24, patient discharged, but requested to report in one month.

Examination of stomach contents after test meal showed HCl + weak; total acidity 35, Uffelman's; general condition improves; gain in weight and strength; no return of symptoms. December, patient considers herself cured, which can not be. No evidences of carcinoma.

(To be continued.)

## THE MEDICAL CORPS OF THE U. S. NAVY.

BY FREDERICK HORNER, M.D.

UNITED STATES NAVY.

In connection with the early history of the American Navy as developed into a distinct arm of the national defense, it is interesting to recall the fact that its embryonic origin was first developed in Virginia under royal authority. As early as 1775 the convention of the colonists of Virginia had directed the Committee of Safety to procure armed vessels for the defense of the colony, and the control and management were intrusted to this committee. Accordingly in May, 1776, the House of Burgesses of Virginia foreseeing the coming struggle with the mother country for the independence of the colonies, and recognizing that the vessels of the merchant marine of James River and border harbors of Chesapeake Bay constituted the elements, if armed and equipped, of a squadron already manned by sturdy sailors who had knowledge of the sea, and commanded by officers of the pluck and experience which have ever characterized the captains of the Marine Service, appointed a Board of Naval Commissioners consisting of Thomas Whiting, John Hutchins, Champion Travis, Thomas Newton and George Webb, who met first in Williamsburg, then the capital of Virginia. These men adopted a plan for the creation of a naval force of seventy vessels which had been employed for purposes of commerce, having been constructed at the Chickahominy Navy Yard, near Norfolk, Va. Among the naval surgeons commissioned for this service during the Revolution were Dr. Balfour, an eminent physician of Norfolk, Va.; Kemp, Lyon, McClurg, Brockenborough, Christie, Reynolds, Sharpless, Pell and others. It was after this period that the seamen and naval forces of the New England States were organized for the national defense. At this period the merchant marine were not usually provided with a surgeon, and physicians who were competent to practice were obliged to go abroad to the universities of Edinburgh or Cambridge to obtain a diploma. In 1764 when the first medical college in America was founded in Philadelphia, now the University of Pennsylvania, and afterwards in 1825 when the University of Virginia had established a medical department, in 1827 the supply of surgeons for the naval service was equal to the requirement, though it may be added in the early days of the colonial period, "physick was not regarded as a fit profession for a gentleman of Southern birth, who, haply was possessed of ample fortune, and had no need to practice a profession."

Among the surgeons commissioned first were W. A. W. Spottswood, Cornick, Harris, Chase, G. R. B. Horner, Brownlee, Whelan Maxwell, Temstell, Squibb, Elisha Kane and others. Surgeon-General

Harris, while chief of the bureau of medicine and surgery contributed to systematize the work committed to the naval medical officers and proved equal to the arduous duties of his office; and with his successor, Surgeon William Whelan, elevated the standard, intellectually, and scientifically, for the admission and promotion of the junior medical officers of the Navy and also aided in promoting the success of the repeated explorations of Passed Assistant Surgeon Elisha K. Kane, in vessels fitted out by Mr. Grinnell and the Navy Department in command of Dr. Kane, and also in expeditions to Paraguay and to Japan in 1851. The war between the United States and Mexico occurred during Dr. Harris's term of office, and the war of the Rebellion in this country during that of Surgeon-General Whelan's term. The surgeons in active service during this period displayed uncommon ability and zeal in the performance of their duties, and their printed reports to the office of the Surgeon-General furnish valuable data connected with the various branches of practical medicine and surgery. A decided impetus for such publications was given to the Naval Medical Corps by the stirring events which then occurred. Under the direction of Surgeon-General J. C. Palmer and Medical Inspector A. L. Gihon, a neat volume of medical essays, compiled from reports to the Bureau, were published by order of the Navy Department. Surgeon R. C. Dean, Medical Inspector, U. S. N., made a valuable report on the naval medical schools of France and England, showing the liberal policy of the governments of those lands toward their naval medical officers. For example, in Great Britain there is established a naval medical school for the Army and Navy at the Royal Victoria Hospital at Netley. Here a per diem of 5s. is allowed the officers, with excellent quarters and subsistence, and according to a late Navy List of the British Admiralty, a liberal pension is allowed not only the widows but the children also, of the medical officers. Dr. J. D. Gatewood, Surgeon, U. S. N., contributed a valuable report on Hospital Statistics of the Naval Hospitals of Europe, showing that the average mortality was as low as 10 per cent. for the Royal Naval Hospital at Great Yarmouth, England. This report was read before the Medical Congress of the Columbian Exposition at Chicago. Among the earliest authors of the Naval Medical Corps who have, from time to time made valuable contributions to current periodical and book literature are Surgeons Ruschenberger, G. R. B. Horner, Foltz, Wilson, Wales, Brown, Wise and others. Among such publications may be enumerated: "Endemic Influence of Evil Government and Medical Statistics of the Island of Minorca," by Surgeon J. M. Foltz; "Medical Topography of Brazil," "Medical Statistics during a Cruise to the Mediterranean" and "Naval Surgery," by Surgeon G. R. B. Horner; "Arctic Explorations in the years 1853-54-55," by Elisha Kent Kane, M.D., U. S. N.; "Naval Hygiene," by Surgeon Wilson; "Mechanical Surgery," by Surgeon P. S. Wales. Such contributions betoken a commendable zeal and industry on the part of the authors, furnish evidence of their talents and erudition, and present examples worthy of imitation.

The second epoch in the history of the American Navy was marked by the occurrence of the Civil War, when a large number of naval surgeons of the Southern States either resigned from the service or refused to take the required oath of loyalty to the Federal Union

and were dropped from the registered list when the reorganization of the Navy was effected in 1861. A small number were true to the old Ship of State, ready to be scoffed at by erring ones, and, perhaps, because of the spirit of an ancestry that had signed the Articles of Confederation, the Declaration of Independence and the Constitution of the United States. Among others of this number were Surgeon G. R. B. Horner and the writer, and of those who also thought they were right were Surgeon Dinwiddie Phillips, of the ironclad *Merrimac* and Surgeon Galt, of the *Alabama*.

The decade which succeeded the return of peace to the country was marked by an accession to the number of naval medical appointees from the Southern States, and during the intervening period the strength and efficiency of the Corps has been greatly developed. The number of 170, the maximum allowed by Act of Congress is meager indeed in comparison with the 502 surgeons of the British Navy, with its Director General a Baronet of the realm, and a corps of inspector-generals; first class, staff officers; second, surgeons and fourth, medical inspector-generals of the royal hospitals at home stations and abroad. In this connection it may be remarked, *en passant*, that American authorities do not show the favor to our Naval Medical Corps, that they do to line officers, who as cadets and ensigns whose education and maintenance at the Naval Academy, Annapolis, cost the taxpayers of the country \$500 a year for each cadet. The surgical staff has no such bonus accorded them at any period of their service by our Government.

Finally, it may be asserted with truth, that the Medical Corps of the U. S. Navy has ever maintained a high professional status, and an *esprit du corps* challenging criticism. Through the efforts of Surgeon-General Tryon, the U. S. Naval Laboratory and Department of Instruction has been founded in Washington City. The courses in bacteriology and analytical chemistry have proved valuable and instructive to the class of Assistant Surgeons, candidates for examination and promotion to a higher rank. The U. S. Naval Museum, now removed to the Naval Observatory Buildings, has already proved useful in developing all that is of value in the sphere of mechanical inventive art, as well as forming the nucleus of a fine library. Surgeon-General P. S. Wales and J. Mills Browne during their terms of office contributed largely toward the success of the Museum and founded in connection with it a Naval Medical Society, before which were read and discussed interesting medical and surgical papers that were published under the supervision of Surgeons Van Reyepen and Beyer. A few retired medical officers of the Navy were Fellows of this society, and were glad to exchange greetings with old friends, and enjoy the privilege of taking part in the proceedings. The Naval Medical Staff has able representative delegates appointed to the annual meetings of the AMERICAN MEDICAL ASSOCIATION, to the Association of the Military Surgeons of the United States, to the various international medical congresses of the world, and the American Public Health Association.

The admirable report of Surgeon-General Tryon urges the necessity of an organized Hospital Corps, well instructed for all duties on board modern vessels of war, and concludes with the statement that thirty permits were granted to applicants, to be examined by a late Board of Naval Medical Examiners; of the

thirty, ten failed to present themselves, five were rejected physically, twelve professionally and three passed the examinations. The Naval Medical Examiners have, in fact, no option than that of exclusion of many talented and learned men from the Naval Medical Corps, because the legal number of 170 surgeons, passed assistant, and assistant surgeons, as already stated, is the number allowed by law, though the Navy of the United States represents a nationality of 65,000,000 people.

The comment may be pardoned that concerning the bill for the reorganization of the *personnel* of the Navy, the legislators of Congress, themselves dependent at times more or less upon physicians and surgeons for relief, surely may be trusted to do right toward the interests of the Naval Medical Corps.

Congress may recall that Passed Assistant Surgeon E. K. Kane proved to be not only equal during his medical service to professional duty, but developed into one of the most renowned captains of the nineteenth century, the discoverer of a terra incognita, Washington Land and an open Polar Sea in higher latitudes than ever before explored, to attain which even the courage and sagacity of a Columbus would hardly have undertaken it, and in the accomplishment of which he solved the mystery—so long desired in vain—of the fate of his illustrious co-explorer, the lamented Sir John Franklin.

Congress knows, also, that Surgeon James M. Ambler proved his heroic mold by remaining with the brave Commander DeLong, choosing death by cold and starvation with him and their comrades, than to accept the offer to escape and seek help.

Congress knows how Dr. John B. Hamilton, when Chief of the U. S. Marine-Hospital Service, with his efficient co-workers rescued hundreds of the fever-stricken citizens of the cities of the Southern States in the midst of the "pestilence that walketh in darkness and the destruction that wasteth at noon-day," by the establishment of refuge camps and the enforcement of prompt, incisive and strict sanitary and quarantine regulations; and with a kindred spirit, Dr. G. B. Thornton, when the Mound City of the West was decimated by a like scourge, with soldier-like courage and vested municipal authority had destroyed streets of houses, and chattels teeming with the germs of a death-dealing plague. And thus, these self-sacrificing physicians with others, who bear the mantle of the Divine Physician and stand between the living and the dead, fearlessly sought to save life; yea, with equal courage with Surgeon Edward Shippen were faithful to duty, as he was when he conveyed an order—Perry-like, of Lake Erie memory—in the harbor of Charleston in the face of the raking fire from the enemy, from one ship to another.

Indeed, it is not presumption to recall the fact that the physicians and surgeons of the United States Army and Navy, during the late fratricidal war, on the assertion of the late Prof. S. W. Gross contributed to perpetuate the Federal Union, since this class as non-belligerents and as represented by the AMERICAN MEDICAL ASSOCIATION, "suffered no disruption of the fraternal bonds which united them as brethren." Men of this stamp are entitled to be fairly dealt with by their peers of the Naval Service, and by the people's representatives in Congress, whatever reorganization of the *personnel* of the Navy may be agreed upon.

## ETHYL BROMID ANESTHESIA IN POST-NASAL ADENOID GROWTHS.

Read before the Chicago Medical Society Feb. 4, 1895.

BY GEORGE MORGENTHAU, M.D.

PROFESSOR OF LARYNGOLOGY, CHICAGO POST-GRADUATE MEDICAL SCHOOL; ASSISTANT SURGEON, ILLINOIS CHARITABLE EYE AND EAR INFIRMARY (EAR DEPARTMENT), ETC.

The subjects of "adenoids" is such a well-worn one that I would not venture to bring it before the society, had I not been encouraged in my doubts as to the proper way of operating on these growths, by a recent discussion of this very question at a meeting of the London Laryngological Society. It appeared there, too, how wide is the diversity which exists as to the choice of the anesthetic, the posture of the patient, etc. Since conditions are different with us, especially resulting from the preference given ether over chloroform by the profession at large, and the popular distrust in which the latter drug is held; since, furthermore, this mode of operation with ethyl bromid has not been described in American literature, I am in hopes that the discussion called forth by this short paper will prove to be out of proportion to its length.

While it is held by many that anesthesia is not to be induced for this operation, I make bold to consider it both cruel and immoral unnecessarily to inflict severe—and often, quite severe—pain on a nervous, terrified, struggling child. The poor little one can not accept an adult's logic; to it this manipulation is as frightful as a much larger one would be to its parent; and the latter, not infrequently, prefers to escape even the momentary pain caused by the extraction of a tooth. It further demoralizes the child, who should look upon the physician as its friend, for whom it will open its mouth when requested to do so. Children have excellent memories for injuries and insults offered them. One little girl, for instance, was held by her father and two other men while the physician amputated the tonsils about three years ago. She can not be prevailed upon to enter that office building again, and still retains the adenoids and an abiding distrust of physicians. To use main force seems to the child's mind as convincing as the wise answer given by the proverbial eagle to the little bird protesting against being devoured, "but I am big, and you are small."

The numerous operations on the non-anesthetized child which one had opportunity to witness or perform at the Berlin Laryngological Clinic appeared unsatisfactory to me (and since then the method has been changed there). I, therefore, advise anesthesia in younger children, but operate without it in older children when there is only a hypertrophied Luschka's tonsil which can be removed *en masse*. Chloroform and ether were employed by me in a limited number of cases. The child lay either on one side, or on its back with overhanging head. Chloroform is not feared without good reason; there were nine deaths in England alone within one year in just this operation. Ether, on the other hand, is very disagreeable to both patient and operator, as it takes much longer

to produce anesthesia, often causes great excitation, and increases the amount of mucus and blood to a marked extent. The severity of the after-effects, nausea and prolonged vomiting, and the undeniable dangers incidental to anesthesia with these drugs, led me to try the method I had seen practiced by Moritz Schmidt, of Frankfurt-on-the-Main. I am now able to report on a series of 100 consecutive cases in which I operated either myself or assisted Drs. Hardie and Holinger. The operation is done in the following manner: The patient's chest is first examined, as ethyl bromid should not be used in chronic heart and lung disease. Then the clothing about the chest is well loosened. I prefer to use the head mirror and reflect the light into the patient's throat. It is advantageous to have the patient on a higher plane than the operator; the patient's chin may then be lowered upon his chest, and the blood made to run from nose and mouth. If the patient is an older and sensible child he may sit upright in a chair, with a sheet about his arms and chest. It is advisable, however, to have an assistant hold a younger child in his lap, in order to restrain it if it should struggle, and to steady the head during anesthesia. A simple mouth gag should be introduced, although it is not absolutely necessary but valuable if a spasm of the muscles of the jaw should set in, as is sometimes the case, and as it saves time. We prefer to administer the anesthetic by holding a common chloroform mask covered with oiled silk closely over mouth and nose. The quantity to be used (1-2 drachms in children; 3-4 drachms in adults) is poured at once on a little gauze or cotton in the interior of the mask; the child may struggle a little in the beginning, but as the drug has a not unpleasant odor and does not irritate the mucous membrane, it is easily and quickly reassured. Often the face becomes flushed, the pulse is increased in frequency, but does not become weak or irregular; breathing becomes slower and a little shallower. In forty to sixty seconds, breathing may be slightly stertorous, the eyes begin to wander, the uplifted arm drops to the side, the right moment for operation has come. Pupillary and conjunctival reflexes do not serve as guides. For two minutes only the patient does not feel any pain. All instruments must, therefore, be within easy reach in order to save time. The tonsillotome can be adjusted accurately and quickly under the guidance of the eye in good light (Moritz Schmidt uses the hot galvano-cautery snare); the other tonsil is amputated with a second instrument. With Gottsteins's modified curved curette the adenoids are next removed, one sweep being made in the center of the vault, and a second and third one on either side. The older form of the Gottstein knife (the instrument is bent nearly at right angles) may then be used to sweep the posterior pharyngeal wall. Finally, if on introducing the finger behind the soft palate, any remnants should be discovered they may be scraped away with the nail. By this time, the child is nearly conscious, although not experiencing any pain; it opens its eyes, looks a little dazed, and appears but little disturbed. Anesthesia, operation, and recovery thus occur in five to seven minutes. The patients are ordered to lie or sit down immediately after awakening. Most of them were able to walk alone in a few minutes. Many left the office or dispensary in fifteen to thirty minutes, usually feeling quite bright and cheerful;

occasionally they complained of a slight headache. Three vomited a short time after the operation. Nausea never was very pronounced. Three patients vomited several times during the day without great nausea; in the evening they were quite happy and hungry. One very high-strung and timid girl of 10 could not, at two different times with an interval of a week, be brought under the influence of the anesthetic.

During anesthesia no alarming symptoms occurred. The pulse was generally quickened, but not reduced in strength. In four cases a spasm of the muscles of the jaw set in, notably of the masseter, which was easily overcome by pressing the spatula firmly on the tongue or behind the last molar, and thus forcing the mouth open. No vomiting occurred during anesthesia, although some had eaten but shortly before. I had seen involuntary urination and defecation occur in Germany—it is reported in adults, too—but we did not meet with a single instance. Probably we do not push anesthesia far enough for that. Twice I observed a peculiar after-effect, which is not easily explained in view of the denial of good observers that the red blood corpuscles are attacked by ethylization. The children presented a grayish, rather ghastly hue in their complexion, which did not escape the attention of their mothers; and on feeling the pulse without their knowledge, I found it accelerated but strong. This state lasted two weeks without producing any discomfort whatsoever. Ethyl bromid is eliminated by the lungs only, sometimes with a garlic-like odor; no traces of free or combined bromin are found in the urine.

It is of the utmost importance that the reflexes are not abolished. The persistence of the laryngeal reflex justifies what would otherwise be a dangerous procedure, keeping the patient in the upright posture. No blood can enter the larynx without producing immediate reaction, *i. e.*, being expelled by coughing. The pieces of severed tissue either adhere to the instrument, or are swallowed or expectorated. As soon as the vault has been cleared, the patient is ordered in a loud voice, to "spit it out." Even when consciousness has not completely returned, the command is automatically obeyed. Most of the blood escapes through the nostrils and the inclined groove formed by depressing the tongue and holding the chin downwards. When the vault is again entered, in order to palpate and scrape away any stray adenoid tissue, the patient is analgesic even if manipulation should be perceived, and recalled later on.

As far as the results of this mode of operating are concerned, we are well satisfied. Recurrence took place in only one case, where Dr. Holinger yielded to the entreaties of the mother to operate on her daughter three times within six months. The parent declared that her daughter always grew stupid when the growths were there. The patient was a girl of 16 who could easily be examined with the rhinoscopic mirror. Dr. Holinger could thus convince himself that none of the growths remained behind after the operations. As far as my experience with forceps goes, it is not possible to remove all the adenoids in the limited time at our disposal. Cutting, as it usually does, transversely, it has undoubtedly caused many severe hemorrhages, primary and secondary, by nipping the posterior ends of the turbinated bodies or the posterior edge of the septum. I know of but two cases of severe secondary hemorrhage.

after operation with Gottstein's curette; and in one, which happened to me, I ascribe it to the fact that I removed but little at the sitting, not having anesthetized the patient, a young woman. Even that popular and vigorously grasping forceps invented by a distinguished member of this Society may in busy hands, when one of them is introduced into the nasopharynx to guide the instrument, be the cause of much unnecessary blood-shedding. The upright position enables the operator to use the Gottstein knife quickly and effectually. The instrument is so ingeniously constructed that it is impossible to do damage with it. In cases where I found great swelling of the nasal tissues, I have applied a weak solution of cocain (4 per cent). The shrinking of the tissues allows the blood to run freely through the nose. The bromid of ethyl we employed with great satisfaction is made by Merck of Darmstadt. It is sold in one ounce, sealed, dark glass tubes. In glass-stoppered vials, it is not reliable. I have found that the liquid had entirely evaporated although the original packing had not been disturbed. The most practical form would be in one-half ounce tubes, just enough for one anesthesia in an adult. It is not safe to keep an opened bottle for any length of time, because the ethyl bromid is decomposed by sunlight or in contact with air. The best preparation is obtained, according to the German pharmacopœia, by distilling a mixture of alcohol, sulphuric acid and bromid of potassium. The product is colorless, of neutral reaction, with a pleasant odor. It must not be confounded with bromid of ethylene; a most dangerous mistake to which one death must be ascribed which was charged to bromid of ethyl. The impurity of the older preparation, and its cost were reasons against its use which do not hold good to-day.

The career of the drug is a checkered one; it has had its ups and downs. It is only just, however, to say that, like the historic queen, it is better than its reputation, and is at present in great favor. Discovered by Serullas in 1827, it was first used by Nunnely, of Leeds, in 1849, and again lauded by him in 1865. He considered it one of the best of anesthetics; a view in which B. W. Richardson declared he fully concurred. In America it was introduced by Turnbull in 1877, and extensively used by Levis, of Philadelphia, Chisolm, Conner and many others. In spite of their enthusiasm based on several thousand successful cases, the reports of a few deaths, notably one by Marion Sims, and the unfavorable results of experiments made by Wood on animals, drove it into oblivion. It would lead too far to follow in detail the arguments advanced by its adherents and opponents, although the perusal of the literature bearing on the subject (New York *Medical Record*, 1880, and other journals of that year) is most fascinating to the student of medical history. In the last five years ethyl bromid has again been taken up by the profession. It is steadily gaining in favor with German laryngologists; the Berlin Clinic reported excellent results in 200 cases, agreeing in nearly every point with our experience. Moritz Schmidt speaks highly of it in his latest book. He performs all the adenoid operations in his office with this anesthetic. German dentists are using it to a great extent instead of nitrous oxid because of the appreciably longer anesthesia. Witzel (*Monatschr. Zahnheilk.*, 1891, October), for instance, after 465 trials, calls it the least

dangerous anesthetic; as much devoid of danger as nitrous oxid. His experience is most valuable, as it includes patients sent from the various clinics at Marburg; among them are six with severe diseases of the heart and lungs; eleven with pulmonary disease, etc. He speaks of the anesthetics as excellent with twenty-eight exceptions. These are given under different headings:

- a. Great excitation in nine cases. Of these, four with much sweating.
- b. Cyanosis in two students somewhat the worse for liquor.
- c. Asphyxia, but rarely with his method (first, a few drops, then the whole quantity of the anesthetic).
- d. Malaise, feeling of lassitude, vomiting.
- e. Urination in three cases.
- f. Great sexual excitement.

But these phenomena, he asserts, will be seen with any other anesthetic. In two cases he could not produce anesthesia with one and two ounces. In six cases he anesthetized the patient twice in one sitting; in two cases, three times.

In regard to the dangers of bromid of ethyl anesthesia, there are numerous and most contradictory statements to be found in literature. I do not wish to conceal that even with the new and purified drug, fatal cases have occurred. While one (Billroth's) would have ended just as unfortunately had any other anesthetic been used because the patient's heart was diseased; while another, occurring on the day after its administration, can not positively be attributed to it; nevertheless there are three cases in which ethyl bromid can not be exonerated. Statistics are, unfortunately, not complete enough to be of value; and, furthermore, the number is not nearly great enough to allow of any definite deductions as yet. Gurlt's statistics (*Arch. Klin. Chir.*, vol. i, 1894) place ethyl bromid between chloroform and ether.

Chloroform, 166,812 cases with 63 deaths—1.2647.

Ethyl bromid, 7,541 cases with 2 deaths—1.3770.

Ether, 26,320 cases with 2 deaths—1.13160.

These figures will certainly be modified in the next report as far as ethyl bromid is concerned, making the ratio a much more favorable one as the number of administrations increases; the Billroth case of the patient with diseased heart turning the scales most unfairly.

The discussion on this subject in the Berlin Laryngological Society (*Berl. Klin. Woch.*, No. 1, 1894) shows well how contradictory are the views held by various observers. While the essayist (Ed. Meyer), relying on 200 successful administrations, could speak highly of the lack of danger and the other good qualities of this drug, Grabower quoted the results of experiments on rabbits. He declares it to be one of the most dangerous of narcotics, if not the most dangerous one. After a few inspirations the pulse rate is greatly increased; later on arrhythmia; then genuine cardiac delirium with utter lack of coördination of the different parts of the heart. In a short time the heart stops. During arrhythmia there is no abnormality of respiration. Thus there is no warning of danger as with other narcotics. Others controverted the right to draw conclusions from experiments on animals in reference to the human economy.

In his "Text-book on Therapeutics," Hare draws attention to the studies made in Jefferson Labora-

tory, which show that the dominant action of ethyl bromid is on respiration, not on the circulatory system. Its effect is depressant, but only seen after excessive doses. Blood pressure falls under its influence to a slight degree, and the pulse is slowed through an influence probably exercised on the inhibitory nervous mechanism of the heart.

H. C. Wood, however, from a series of experiments made upon lower animals, has arrived at the opinion that it acts upon the heart in a manner similar to chloroform, although its influence is not so depressing. A more recent investigator (Brubacher) found, in experimental intoxication of rabbits and guinea pigs, that the heart always continued to beat regularly and powerfully after respiration had ceased.

Schneider, Professor of Dentistry at the University of Erlangen (*Monatschr. Zahnheilk.*, May, 1890), who uses ethyl bromid extensively in practice, made a most searching series of experiments in the Physiological Laboratory. His deductions appear well founded, and are as follows:

While it may be admitted that under the influence of chloroform the red blood corpuscles are disintegrated, producing fatty metamorphosis, we must deny a similar action to ethyl bromid in every respect; believing that we proved by microscopic, chemic, and physical examination:

That bromid of ethyl can not produce any change whatsoever in the red blood corpuscles.

That bromid of ethyl, on account of its lower boiling point, is very rapidly eliminated from the body by the lungs.

We, and with us most of the authors, have observed that even in deepest bromid of ethyl narcoses, the pupils are hardly contracted. This proves that these vapors have not an energetically paralyzing influence on the medulla, because the narcosis is reduced to a previous stage by the rapid elimination of these vapors by the lungs. It was demonstrated, moreover, by the hemodynamometer that the blood pressure always suffices for an exchange of gases; and, finally, the sphygmographic curves, of which the author made a great number, show hardly any change in the pulse tracings. This proves that contraction of the muscles of the vessels takes place while most chloroform tracings show paralysis of the vasomotors. There is a slight diminution of the blood pressure from reduced innervation. That is to say, cardiac alterations are much less than in chloroform narcosis. With at least as much right as it is maintained of ether, bromid of ethyl has only a slight depressant action on the heart; and death from ether results from paralysis of the respiratory center. When ethyl bromid was administered to animals in fatal doses respiration stopped much sooner than the heart, which continued to beat regularly and vigorously after respiration had ceased.

After all, laboratory and animal experiments do not seem to bring us much nearer to a universally acceptable solution of these questions. The long and bitter fight between chloroform and ether partisans is still raging. Until we have an absolutely safe anesthetic, if that is possible, we must content ourselves to run risks. Even if ethyl bromid should prove to be more dangerous than ether, the incomparably shorter duration of anesthesia would outweigh the apparently greater security of etherization. It is a question which must be decided by many thousands

of clinical experiments, as it were. The opposing views have been presented impartially, without allowing my gratitude for the time and trouble saved by the use of this anesthetic to blind my judgment. The manifold and obvious advantages of this mode of operation will, I may trust, recommend it to many as well worthy of extended trial.

Venetian Building.

## THE IMPROPER USE IN MEDICAL LITERATURE OF CERTAIN WORDS AND PHRASES.

BY CASEY A. WOOD, M.D.

PROFESSOR OF OPHTHALMOLOGY IN THE POST-GRADUATE MEDICAL SCHOOL, CHICAGO.

In one of his published letters, Oliver Wendell Holmes writes: "I've sometimes made new words. In 'Elsie Venner' I made the word chrysocracy, thinking it would take its place—but it didn't; plutocracy, meaning the same thing, was adopted instead. Oddly enough I had a letter from a man to-day asking if I did not make the word anesthesia, which I certainly did."

The life history of words and expressions, medical terms included—how they came to be used at all—how some of them, after enjoying a period of prosperity, even of aristocratic connection, sank into obscurity—how some of them were resuscitated and afterwards became a part of the speech of every-day life—how certain candidates for favor were rejected while others were taken up, fêted, caressed, and finally became immortalized in the common dictionary of the language—all this forms a story of the greatest interest. It may also be pointed out that words endure on account of some quality inherent in themselves or because of their peculiar environment or in virtue of both. A medical term survives when there is a great need for it and when its form is pleasing to the literary sense (if one may use that phrase) of the community.

There is quite a large number of medical terms knocking for admission into the fold of our scientific vocabulary, either as entirely new forms or as later and better representatives of old ideas. What proportion of these will be adopted into the growing family of medical terms remains to be seen. Meantime their employment is entirely unauthorized.

The following sentences contain examples of the improper use, in this sense, of certain words that occur occasionally in our medical journals. The objectionable words are italicized: (a). On the next day we *operated* the child. (b). Care should be taken not to *operate* the cataract too soon. (c). If the *operated* eye remains quiet it is better to interfere early. (d). These symptoms may be due to a swollen *turbinate*. (e). The *iritic* reflexes were found to be normal. (f). If we wish to measure the total ametropia, it is usually necessary to employ a *mydriatic* (cycloplegic). (g). It is often difficult to *refract* such a patient. (h). In cases where the *refracted* eye is shown to be emmetropic (i) the *refractor* places a convex lens before his own eye.

(a), (b), (c), In Vicente Salva's Spanish-Spanish-Latin dictionary, the nearest approach to a Latin equivalent of the Spanish word *operar*, to operate upon, is given as *operationem chirurgicam peragere*. The English language has in this particular followed the Latin construction more closely than the so-called Latin languages themselves. There is no single transitive verb (derived from *opus*) in either tongue

that conveys the idea of the performance of a surgical operation. If there be such it will be found in the works of modern writers of Latin who, under German, French, Italian or Spanish influence, have coined a corrupted derivative (*operare*) from the deponent verb *operari*, which has quite a different significance from *operar*, *opérer*, *operare* (Italian) and *opereiren*, which are, in a perfectly legitimate sense, transitive. It is probable that the above mentioned and objectionable use of the English verb may be traced to the same source. This probability will be brought out by the following short sentences and phrases taken at random from foreign publications: *Ich habe das operirte Auge sehr oft untersucht. Einen Blinden, die Augen, den Staar u. s. w. operieren. Ce chirurgien est habile, il opère parfaitement bien; il a opéré dans la journée deux hommes qui avait la pierre. Il primo a operare con successo l'estirpazione della laringe fu un italiano.* So that while the continental surgeon we are best acquainted with usually *operates* his patients or their organs, we must continue to operate *on* or *upon* them.

(d). This word is never used as a noun, although there is abundant authority for the employment of *turbinal*—meaning a turbinated bone. For example, in Huxley's "Anatomy of the Vertebrates" occurs the following: "Forming the floor of the front part of the nasal chamber on each side is a large concavo-convex bone . . . which is commonly termed a *turbinal* . . . does not truly correspond with the *turbinals* of the higher vertebrata." This pretty well disposes of the argument (in favor of "turbinate") that we have no single word in English to designate a turbinated bone.

(e). A moment's consideration of the fact that the adjective *iritic*, like *neuritic* and *pleuritic*, has to do with the inflammation of the part designated by the first portion of the word should be sufficient to prevent the mistake of using it to refer to the part itself. On the other hand, this improper use of *iritic* is not uncommon; I have lately seen it so employed in one of our most widely known medical journals. Legitimate adjectives (derived from *iris*, gen: *iridis*) are numerous enough; there is good authority for *iridal*, *irian* and *iridian*, not to mention the frequent and proper use of the noun *iris*, as an adjective.

(f). The use of *cycloplegia* and *mydriasis* as synonymous terms and of *mydriatic* and *cycloplegic* as interchangeable adjectives and adjective-nouns is one of the commonest errors one meets with in medical literature. A mydriatic may be, but is not necessarily, a cycloplegic, even though a cycloplegic is usually a mydriatic. A giant is always a man, but men are not necessarily giants. The electric current and a quarter-grain solution of cocain are under certain conditions mydriatics but neither of them is a cycloplegic. If one wishes to refer specifically to the dilatation of the pupil the ancient term *mydriasis* should be employed, reserving the modern word *cycloplegia* (from *κυκλος*, a circle, *i. e.*, the ciliary ring, and *πληγη*, a stroke) for indicating a paralysis of the ciliary muscle.

(g), (h), (i). It is not uncommon to witness the incorrect employment of these words, even by those who make some pretensions to scientific accuracy. If we think of their etymology (or consult any dictionary) it will not be difficult to show the inaccuracy of connecting the idea of personality with any

of them. One may properly *measure* or *determine* the refraction of a patient's eye,—but ought not to say: "I advise you to refract Mr. Jones," or "You had better refract both his eyes," which would be tantamount to condemning Mr. Jones or his eyes to be broken up or bent back (*re* and *frangere*). In the same way the noun, *refractor*, has been incorrectly given a new meaning—that of a person who determines the refraction of the ocular media, *vulgo*, a man who fits glasses. One meaning of *refractor* is that of a telescope and the idea is of something that refracts, or bends from their course, light or sound waves.

Although it is undoubtedly true that we can not with propriety speak of *refractor*, *refract* and *refraction* apart from a *thing*, yet it can not be denied that the phrases, "to measure Mr. Jones' refraction," and "to determine the refractive condition of Mr. Jones' eyes," are entirely too clumsy and eat up too much time. Already, in England especially, the shorter expression "to measure Mr. Jones" (for glasses) is in vogue. In practice this would be less objectionable (to Mr. Jones himself and others) than "to refract Mr. Jones," who might be hard to bend or break.

There is a demand, but less urgent, for some term that will designate the person doing the refraction work above referred to, but that "refractor" meets this philological want is at least doubtful.

Many other examples of the questionable use and application of terms in medicine might be given, but such a task may well be undertaken by some other writer better qualified to complete it.

## SCARLATINA AND THE STREPTOCOCCUS INFECTION.

Read in the Section on Diseases of Children at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY ROSA ENGELMANN, B.A., M.D.

PROFESSOR OF THE DISEASES OF CHILDREN IN THE POST-GRADUATE MEDICAL SCHOOL OF CHICAGO; ATTENDING PEDIATRIST TO THE UNITED HEBREW CHARITIES FREE DISPENSARY, CHICAGO.

The clinical history and symptomatology of scarlatina point to a virulent infection. Streptococci are found in the throat, cervical glands and other lymphoid structures, as well as in the blood, pleural, pericardial and peritoneal secretions, internal organs and skin of patients succumbing to this dread disease.

Mr. Bergé, in a paper read at a recent meeting of the Biological Society of Paris, maintains that scarlet fever is the result of a local infection by the streptococcus. In an article upon "The Local Lesion of Scarlet Fever," Dowson speaks of the "accidental inoculation of the tonsil by minute scratches while taking food."

No one questions the common etiology of idiopathic and surgical scarlatina. Their relation to puerperal fever and pelvic suppuration is admitted. Consequently their affinity to any local abscess formation, septicemia or pyemia must be conceded. No clinician has failed to observe the likeness of the course and progress of an attack of scarlet fever to one of septicemia or even pyemia. Post-mortem records emphatically corroborate this characteristic and harmonize the seeming conflicting facts with the specific microbic distinctions and diversities. With reference to the latter and the progressive changes in the biologic field, Hueppe says: "For a better enlightenment, and under the influence of a

strictly scientific apprehension of the etiologic problem, these rugged differences are disappearing." In the effort to determine the cause of such apparently diverse conditions as erysipelas, scarlatina, septicemia or suppuration, the specificity of the streptococcus erysipelatis, the streptococcus scarlatina, the streptococcus pyogenes may have been too markedly dwelt upon and their almost biologic indistinguishability overshadowed. Osler believes "the rash of puerperal fever and of surgical scarlatina to be the red rash of septicemia." To me, it seems reasonable to push this thought to its logical conclusion, viz., to call the red rash of *idiopathic* scarlatina a septicemic eruption. Such complications as endocarditis, arthritis, etc., are doubtless pyemic, and possibly indicative of but a more malignant and extensive scarlatinal incursion.

Fraenkel, Baumgarten and lately Knorr are avowed advocates of the identity of the streptococcus erysipelatis and the streptococcus pyogenes. In 1889 Fraenkel by erysipelas culture inoculations, caused purulent ophthalmia in one case, peritonitis in another and an abscess of the skin of the back in a third case. This proved to his mind "the identity of the two," while "clinical differences in the disease were due to the mode and locality of the infection; perhaps also to the quantity of the virus and disposition of the individual." The identity of the scarlatinal and pus germ is as yet undetermined, although by many, they and the streptococcus erysipelatis are considered as different varieties of one and the same species. It yet remains to bring this theoretical work into consonance with practical clinical experience.

Spatswood in a recent article entitled "Infant, 1 Month old with Erysipelas of Head, Face, Neck, Trunk and Extremities," traces the infection to the mother, who four days after delivery came down with puerperal fever. Dowson reports a case of scarlet rash superimposed upon an otorrhea. Gimmel reports two adult cases of erysipelas developing upon a previous scarlatinal attack. In the one case, scarlatinal desquamation took place on the sixth day and upon the tenth day was followed by a localized facial erysipelas exfoliation. He is of opinion that "the scarlatinal poison may often have, just as in erysipelas, its point of entrance in an epidermal injury." . . . "It is a question with me, whether or not in these cases the etiology of the two processes was not identical; for the erysipelas occurred during the desquamative stage of scarlatina and the contagion carried to a nasal excoriation by the desquamating skin."

As early as 1840, Braun calls attention to the fact of many contemporaneous attacks of angina and facial erysipelas. A scarlet fever case of Gläser's in whom great flakes of desquamating skin exposed the deeper, oozing, rete malpighii suggests to me the possibility of this disease invasion through the skin as well as through the usually accredited portal, viz., the tonsils.

In the *Archives of Pediatrics*, April, 1893, I reported a case of erysipelas, contracted by the father through the scratch of his child's fingers, the child at the time being sick with scarlet fever.

In February, 1894, I was called to see a boy suffering from severe scarlatina which prevailed in his neighborhood. There was an enormously large bilateral cervical adenitis. The matter was deeply seated and caused some respiratory embarrassment. The patient was in a dangerously septic state, much

enhanced by a superadded right facial erysipelas. The surface was swollen, brawny, glazed and involved the eye and neck of that side. Unfortunately, I had no further opportunity for observation of this interesting case. But I was again profoundly impressed with the probable identity, or at least possible interchangeability of the pyogenic, erysipelatos and scarlatinal microorganisms and their correlative aggression.

Jordan, in the *Centralblatt für Bakt.*, 1891-92, concludes that: "Erysipelas is etiologically not a specific disease." He is criticised for "so many conclusions on so few cases." I must plead guilty to the same indictment, but because of the importance and interest of my theme, present it for consideration. The etiologic and clinical parallelism of scarlatina, septicemia and erysipelas having been presented, their points of non-resemblance, variable intensity, individual susceptibility to, or immunity from, must be explained. Their diverse manifestations need interpretation; for in the one instance an abscess or septicemia obtains, in another, erysipelas, and again in a third case scarlet fever.

Varying virulence is probably dependent upon the life history of the germ, its different avenues of entrance and the natural and acquired immunity of the invaded organism. The character of the disease may likewise depend upon the vulnerability of the individual; some responsibility being attached to age, heredity, congenital disease, anatomico-physiologic conditions peculiar to age and personal environment.

An infectious agent is often innocuous to a healthy individual, illustrated by the presence of Löffler's bacillus in the throat of healthy persons. Diphtheria and scarlet fever are preëminently dangerous diseases of childhood. Why? Not alone do adenoid tissues, especially accessible to bacterial encroachment, prevail in youth, but this period of life has anatomic structure of fauces, larynx and skin peculiar to it. Again, a great majority of the child world are born with a rachitic, tubercular or syphilitic taint. They are subjects of a lymphatic diathesis, particularly prone to the streptococcic onslaught. In childhood, mucous membranes and skin are to some extent unripe and tender, and their peripheral layers easily succumb to the deleterious effects of implanted microbes. Large assailable epidermic surfaces are perhaps exposed to a diffuse and overwhelming incidence. Scarlet fever results; its mildness or severity gauged by the quantity, virility, extent and penetration of the overpowering force and the age, health or disease of the besieged organs and tissues. The sheltering care and environment of childhood ordinarily prevents the grosser lesions necessary to the inception of erysipelas and ordinary wound septicemia; adult exposure diseases. Environment is here a great factor. The horny, mature, epidermal layer also withstands, consequently localizes, the streptococcic irruption. Erysipelas results; the graver, the larger the implicated surface. Grosser injuries and inundation of the blood by the streptococcus determines a septicemia. A lymphatic streptococcic incursion, a final connective tissue space involvement, determines abscess formation. Idiopathic erysipelas has disappeared from the nomenclature. Idiopathic scarlatina will eventually meet a similar fate for the same reason. The association of surgical scarlatina and puerperal fever are regarded as modified scarlet fever. Erysipelas may in the future be considered an analogous variation, due to differ-

ing essential character and inherent quality of tissue attacked.

As anthrax displays three forms of disease consequent upon the entry of the bacillus into different regions of the body; so might the streptococcus give rise to diverse manifestations according to its mode of entry through the adenoid, mucous, serous, epidermal tissues or blood. When we consider that the incidence of scarlet fever is only 5 per cent. it does not compare unfavorably with that of erysipelas and septicemia over which such a cry of susceptibility and immunity is not raised. Heredity, perfect health and fully developed structure may account for natural scarlatinal immunity. A previous attack or a protective blood serum inoculation, as demonstrated by Ashmead, produces artificial or acquired immunity. However, positive scarlatinal immunity can not be sustained in the face of accredited cases of second independent attacks.

The subject of immunization will be nearer solution with the development of the toxin and blood serum therapy questions. Thus future therapeutics will be directed into: 1, the antiseptic; 2, the antitoxic lines.

Before closing, I wish to place myself upon record as strenuously opposed to the use of inunctions in scarlatina; for I have long believed that the diseased skin and secondarily the kidneys, by reason of an oily lacquer are made to carry an additional burden. Arnheim, Unna, and recently Sskelow, have proved that in scarlet fever the respiratory and secretory function of the skin is seriously involved; consequently inunctions but aggravate this condition and cause secondary nephritic complications. In the face of this evidence, warm antiseptic baths had better supersede so dangerous a procedure, thus promoting physiologic function and meeting anti-bacterial indications. Through biologic research we again see surgical cleanliness invading the domain of medicine. To sum up:

1. A specific scarlet fever germ or toxin is not yet demonstrated.

2. The disease is associated with a streptococcus infection.

3. A streptococcus admitted to be the cause of surgical scarlatina and puerperal fever.

4. A streptococcus admitted to be the cause of erysipelas.

5. The frequent association of the latter with puerperal fever and it in turn with surgical scarlatina.

6. The relation of idiopathic scarlatina to surgical scarlatina and puerperal fever acknowledged.

7. The identity of the streptococcus pyogenes and erysipelatis advocated.

8. Clinical records showing the association of supuration, erysipelas and scarlatina in one and the same subjects, suggestive of the parallelism of these three infections and the probable biologic identity of these several streptococci.

9. Clinical differences and varying susceptibility to the one or the other due to heredity, age, anatomico-physiologic conditions, congenital disease, environment, life history of the invading host and its avenues of entry.

10. Disappearance of idiopathic erysipelas from the nomenclature. Analogously, idiopathic scarlatina may meet a like fate.

11. Natural immunity due to heredity and healthy fully developed structure.

12. Acquired immunity from antitoxins of the disease or through blood serum therapy that will revolutionize the treatment of this dread disease.

13. Inunctions disapproved of. Antiseptic baths better meeting anti-bacterial and physiologic indications. 3353 Indiana Avenue.

## THE VAGINAL DOUCHE IN ITS RELATIONS TO BLENNORRHEA IN THE FEMALE.

Read before the Louisville Academy of Medicine, Feb. 18, 1895.

BY E. R. PALMER, M.D.

PROFESSOR OF PHYSIOLOGY AND GENITO-URINARY DISEASES IN THE UNIVERSITY OF LOUISVILLE, KY.

To be concise, to avoid irrelevancy, to be up to date, to be orthodox, is the aim of this paper.

What is blennorrhoea or gonorrhoea, as you may please to call it? The following quotations from Fin-

ger<sup>1</sup> embody my answer of this question and will be the basis of my argument:

"So many positive inoculations have been made that doubt of the pathogenic character of the gonococci is hardly possible at the present time; in fact its etiologic significance is not recognized universally except by a small group of French writers."

Further on, after viewing the full history of laboratory research in this matter he says: "If we make a résumé, the following facts may be regarded as well established:

"1. The gonococcus is found in all cases of suppuration of the mucous membranes, especially of the genitalia and conjunctiva which are described clinically as gonorrheal.

"2. It is absent in all non-gonorrheal processes.

"3. Pus free from gonococci does not produce gonorrhea.

"4. Pus containing gonococci produces gonorrhea.

"5. The microörganisms which are cultivated from gonorrheal pus, but which are not identical with the gonococcus do not produce gonorrhea.

"6. The gonococcus cultivated from gonorrheal pus produces gonorrhea with distinct increase of the inoculated microörganisms."

In the comparatively modern literature of gonorrhea that has, in its full fruition led up to the evolution of the laparotomist and his hospital, Van Buren stands undeniably first. It is now quite thirty years since he wrote: "More people die of clap than do of syphilis." Like most prophetic warnings his statement was long ignored and unappreciated. Ten years later, Noeggerath "wrote himself down an ass" in his paper on "Latent Gonorrhea and Its Influence on Fertility in Women." The story is a long one and instructive as well. Nothing but the *pudor*, the false shame that surrounds it, has kept it from resounding through the columns of almost every phase of literature.

Noeggerath's second pronunciamento came in 1876, yet as late as 1884, Milton, the most voluminous writers on gonorrhea of ten years ago, refers to specific endocervicitis, endometritis and ovaritis as *complications* of an original specific vaginitis. Finger (*op. cit.*) says: "I still remember when it was impossible for me to demonstrate a trace of blennorrhagia on examining a woman from whom a man was proved to have acquired acute gonorrhea. Not alone could the diagnosis not be made in many cases, but the severity of the process in women was not recognized. The knowledge of the process was confined to the recognition of vaginitis, vulvitis, abscess of Bartholin's glands and urethritis. The latter was regarded as very rare (5 per cent of all blennorrhagic females—Zuissl). Very bold syphilologists ventured to speak of an 'endometritis cervicalis blennorrhagica.'"

In 1874, Bumm first called attention to the cervical canal as the frequent site of gonorrhea; and although the gonococcus of Neisser was demonstrated in 1879, it was not until 1891 that Kratter insisted on the microscopic examinations of secretions and curettements before making a positive diagnosis.

Currier ("Morrow's System," 1893), while questioning somewhat the absolute relationship in the matter of cause and effect between the coccus of Neisser and gonorrhea, rates himself a specificist in saying: "Gonorrhea in a woman always implies a

precedent gonorrhea in some one else . . . it never exists *de novo* either in man or woman."

I am indebted to the article by Currier just referred to for much of the following history. He says: "In recent times it has been seriously questioned by more than one thoughtful writer, whether gonorrhea of the vagina ever exists as a primary condition."

Bumm, in 1891, after a study of fifty-three cases of gonorrhea in the female, found that the cervical endometrium was the seat of gonorrhea in 75 per cent. of the cases, the corporeal endometrium in 15 per cent., and the tubes in 3.5 per cent. "Formerly," said he, "I questioned the existence of vaginal gonorrhea in adults; now I believe it seldom occurs in adults as an acute process and *never as a chronic one*."

Sänger finds gonorrhea most frequent in the cervical endometrium. He holds that while the vagina necessarily receives this discharge it is not always influenced by it.

Sternschneider finds the urethra the most frequent site of acute, and the cervical endometrium of chronic gonorrhea in the female.

Erand demonstrates the frequency of cervical gonorrhea by curettement. In common with other observers, he believes that the exemption of the vaginal mucous membrane from the disease is due to the character of its epithelium (pavement) which is not favorable to the growth of the gonococci. He holds that gonococci found in vaginal secretions are migratory.

Horand gives some interesting statistics in that they contrast in this matter, childhood and adult life. He states that in eighty-five female children with gonorrhea he found vaginitis in sixty-eight. In twenty of these the vagina alone was infected.

Currier aptly refers to the structural difference between the vagina of children and of adults as an explanation of this. In the very young the vaginæ are lined with an exceedingly soft, delicate epithelium and are or should be unused and almost sealed passages, while in the adult, with her descended womb and recurring menstuous flow to say nothing of other influences, ablutions, etc., the resistant pavement protective speedily hardens and with the many benign and septic germs that innocently find lodgment there, some quite probably inimical to the coccus of Neisser, it is not at all a matter of wonderment that her vagina is almost absolutely proof against the disease.

To summarize: Gonorrhea in the female is ordinarily anything but a vaginitis. It attacks the vulva and its appendages, the urethra, the uterus and even the tubes and ovaries, sometimes, notably in children and young girls, the vagina. But in such cases it is always of an acute and so temporary type; a type which because of its necessarily concomitant symptoms is not conducive to contagion. Need I enlarge upon the inferences to be drawn from this array of facts? That the vaginal douche if used as a curative agent for a presumed specific vaginitis, is useless must be apparent to all, and in the light of modern science the *strong* zinc or alum for the woman, as a parallel of the *weak* zinc or alum for the man, is a thing of the past. So, too, of boric and bichlorid and permanganate and all of the growing family of curative specifics, all are futile in vaginal douching. Yet the douche has its place and wisely used this is unquestionably a place of the highest importance.

<sup>1</sup> Blennorrhæa of the Sexual Organs, by Dr. Ernest Finger; translation, third edition. Wm. Wood & Co. 1894.

What is it? First, it is a prophylactic agent. We recognize how feeble the hope of prevention is, where a lacerated surface receives friction in the sexual act, with a chancre. But not so with the gonorrheal virus. Here the prompt douchment with a fountain syringe, hot water, and, say a dash of vinegar may be productive of great good. Here is rational hope of escape from infection, and with statistics demonstrating the cervical canal to be the commonest site of infection, I would in the abstract say that a thorough hot douchment of the vagina, the subject recumbent, in every case where risk is incurred, would in its results alone justify the retention of the vaginal douche in genito-urinary practice. Beyond this it has, as a rule, two purposes in gonorrhea and two only: 1, for cleansing and disinfection, with, say, carbolic acid or some other of the creasols, or with simply warm water, non-curative but of much worth; and, 2, its use as a means of applying the soothing influences of moist heat to those inflamed and sensitive organs, the uterus and its appendages. Here it may be undoubtedly made fruitful of much good; yet here unless it be desired in its use to at the same time wash from the vagina the migratory virus, I would suggest that much greater benefit will accrue if the vaginal douche be given *in the rectum*.

## DISCUSSION.

DR. L. S. McMURTRY—The paper read by Dr. Palmer is too valuable a one to be allowed to pass without discussion. It is a clear cut syllabus of facts from beginning to end, and I indorse it thoroughly. Van Buren's statement was indorsed by Lawson Tait in his great work, and in all probability Lawson Tait never saw Van Buren's writings. The statement referred to was that of the two diseases, gonorrhea was much more severe and dangerous to life than syphilis, and in late years the profession had recognized this. As the gonococcus finds a nidus in the cervical canal, the vaginal douche as a curative measure is useless, the specific virus being lodged where it can not be reached. After the acute symptoms have passed little is heard of it as a chronic malady; it is in the tubes; a gonorrheal salpingitis develops, the pus leaks out in cavity, peritonitis increases and it is the severe general symptoms which bring the patient to look for advice and treatment. It is true, radical measures can cure, but if only the lower mucous membrane is affected the patient is not invalided and the physician is rarely consulted.

DR. W. H. WATHEN fully indorsed the conclusions of Dr. Palmer's paper, and was impressed by the statement that the vaginal mucous membrane is seldom involved in gonorrhea. He had frequently examined patients with gonorrheal discharges and frequent micturition, and from a microscopic view there was no change in the vaginal mucous membrane, and this must be accounted for by the resistance this membrane has for the gonococcus. He does not know what position to take in regard to douches in specific vaginitis. Hot water is as good as any antiseptic; patients are benefited by frequent hot douches, and patients thus treated have not developed pus tubes. If the gonococcus has invaded the cervix and uterus in acute cases, it is only the superficies; it should be curetted and washed with a 1 to 5,000 bichlorid solution, and tamponed with iodoform gauze. Gonorrhea is not so frequently the cause of pus tubes as was formerly believed, but it is oftentimes the cause, especially in young married women who have married men who thought themselves cured of a gonorrhea. Now can any one tell what percentage of involvement of the vagina, uterus and tubes has been due to the gonococcus? The pus tubes removed, if no gonococcus is found does not indicate that it was not there; the gonococcus is a sensitive bacteria. In the large chronic pus tubes no gonococci are found. The older and larger the tube the less virulent the pus.

DR. DUGAN said that the absence of the gonococci from the pus in tubes is an evidence that the pus is not due to this organism. Scraping of the endometrium is not effectual, because the gonococcus is not satisfied with the surface, but dips down. The primary lesion is a stricture analogous to the stricture of the urethra in the male. The septic bacteria or those of suppuration are associated with the gonococcus

the drainage is interfered with on account of the stricture and an abscess results, formed by the bacteria of suppuration.

DR. FRANK stated that Dr. Palmer had explained why the vagina is not affected by the gonococcus. Gonorrhea does not exist in pavement epithelium surfaces, and in all cases in which there exists gonorrhea with a discharge it comes from the uterus or cervix. A vaginal douche is of no avail as a curative measure, but it may give some relief. Dr. Dugan has explained why the gonococcus is not found in the pus of pyosalpinx. The gonococcus invades the deeper structures; it is found in the tissues on section. He had demonstrated in one case in which there was from one to one and a half ounces of pus in a pyosalpinx, the presence of gonococcus. Treatment of gonorrhea should not be by the douche but by applications to the uterine mucous membrane, curetting and drainage, taking away the mucous and some of the glandular structure. This may not prove effectual, as these glands dip deep down in the muscular coat, and to have regeneration of tissue some of it must be left. The gonorrhea may travel by means of the lymphatics. The paper read by Dr. Palmer is interesting and timely.

DR. J. B. BULLITT complained that this most excellent paper read by Dr. Palmer had left us in rather a hopeless state, as he had offered no treatment to take the place of the vaginal douche, which even now many believed to be the only treatment, and he knew that all would be obliged for a treatment to be advised.

DR. McMURTRY asked if gonorrhea in male or female ever got well spontaneously.

DR. PALMER answered that nine women in ten never get well and a large percentage of men do not. Almost all of the speakers had approached the subject from a different standpoint than he had treated. He rather looked to the possibility of the disease being transmitted to men, and they, in turn carrying it to the marital couch. The pus in the pus tubes is different from the pus in the urethra; the gonococcus is a dainty organism, not content even with the urethra, for a drop of serum obtained from the former five days after the development of the disease has been found to contain the gonococcus. Of all organisms the gonococcus is a burrower, and all authorities show that it is want of care and persistence on the part of the examiner which causes him to fail to find the gonococcus. He had under his care at present a girl 14 years of age who had never menstruated, but why had a profuse gonorrhea in the discharge of which the gonococci had been found by Gram's method.

The left vulvo-vaginal gland was involved, there was vaginitis, vulvo-vaginitis and vulvitis. Bichlorid 1 to 2000 douche had been used for one week, and at the end of that time, after cleansing thoroughly he could not touch the uterus with his very long finger. A virginal speculum was introduced and the entire vagina was as raw as any raw meat he had ever seen, the cervix could not be found, and the conclusion was arrived at that the patient had a virginal uterus which had not descended from the abdominal cavity. This case was cited to show the difference between an adult female with gonorrhea and a child; in the latter there occurred a vaginitis. Nine out of ten men contract gonorrhea from women who have this disease in the subacute or chronic stage. If in the acute stage they could not receive the male organ on account of the pain. In acute gonorrhea of the female there is no sign, unless there be a urethritis or vulvitis, until the cervix is reached; cleanse the vagina and you see nothing indicative of inflammation but a tender cervix, and a flow of pus from the canal. The gonococci may remain here for fifteen or twenty years. In the case of the girl with gonorrhea, fully one ounce of pus was mopped out, this alone showing the inefficiency of the douche, which had first been given thoroughly. In the treatment of adult females, in a suspected case it is better to use a powerful chemic agent rather than the knife or curette. Churchill's tincture of iodine is good; this should be carried up and allowed to lie there, asking the patient to possess herself with patience, perhaps making two or three applications at one sitting. The douche is good for cleansing purposes. The cervical canal is the seat of gonorrhea in 75 per cent. of all cases, the vagina is never the seat of chronic gonorrhea. The gonococcus lets the vagina alone. Rather send the water up into the rectum, and by its proximity let it bathe the ovaries, and obtain a soothing action against the inflamed parts. The subject, as before stated, should be looked at from the standpoint of the general public rather than the surgeon's chasing after pus tubes. In conclusion, he would state that when gonorrhea is treated in the female do not treat the vagina, but the cervix; the vaginal douche is absolutely useless as a cura-

tive measure. He has the record of one case of gonorrhea of the mouth, but the mouth with its seventeen different kinds of bacteria is practically proof against the infection by the gonococcus. It is the exceptions which prove the rule. Introduce the speculum, cleanse the vagina well, disinfect the exposed surfaces, in old cases curette the cervix, then apply the medication; but if the cervix is lacerated use nitrate of silver and burn thoroughly. Introduce an antiseptic tampon to absorb the discharges, which should be withdrawn at the office, and always treat the cervical canal instead of the vagina.

The youngest case of gonorrhea which Dr. Palmer had seen was 3 years of age. Twelve years ago a man gave his pregnant wife gonorrhea, the child was born and developed a gonorrheal ophthalmia. The grandmother went blind from gonorrheal ophthalmia developed from the child, and two sisters, 3 and 5 years old developed gonorrheal vaginitis from the same case.

## A CASE OF HYPERTROPHY OF MAMMARY GLANDS.

COMBINED WEIGHT FIFTY-TWO POUNDS—EXCISION—  
RECOVERY.

BY JOHN B. HAMILTON, M.D.  
CHICAGO.

July 19, 1894, Mrs. P., of Lancaster, Wis., was brought to the Presbyterian Hospital by her physician, Dr. F. E. Strong, of Lancaster, who gave me the following history:

"Mrs. P., age 32, had ordinarily good health up to the time of her marriage eight years ago. Began to menstruate at usual time. At 12 years of age had scarlet fever, and when 16 began to have slight irregular pains in both mammary glands. During her first pregnancy when six months advanced, the breasts began to enlarge and became painful. At this time she was very sick with malarial fever and remained so until eight months, when twins were born. Two weeks afterward breasts had resumed their natural size. During second pregnancy they began to enlarge at second month, but did not attain their former size. The child was born at term and nursed from the nipple, which the first did not do. In fall of 1893, just before her third pregnancy, the breasts began to enlarge a third time. She grew weak and an abortion followed at five months; the breasts did not diminish in size, but increased until she came to the hospital. The right breast measured forty-two inches in circumference at the nipple and the left thirty-nine. The right breast measured thirty inches around the pedicle and the left twenty-seven. The right breast measured fourteen inches from the nipple to the pedicle, and the left thirteen and one-half. She was unable to walk without assistance owing to the great weight and bulk of the breasts. The drawings herewith from a photograph, show the appearance of the breasts.

The enormously enlarged veins, the great size of the tumor and the history of former cases, made operation an object of some solicitude on account of the danger of hemorrhage. The first operation was done in the clinical amphitheater of Rush Medical College, July 21, 1894. I had a couple of long skewer pins made and thrust them through the pedicle. I then cast a stout rubber cord between the pins and the chest, and drew them tightly but separately from each side. The breast was then removed by cutting two flaps of skin from the tumor, reflecting them respectively upward and downward, and enucleating the gland; the vessels were secured without difficulty. The hemorrhage was considerable, but it was almost entirely

from the blood remaining in the gland, as the constriction had prevented arterial hemorrhage. The great bulk of the gland prevented the emptying of the blood vessels by compression, although something was done in that direction by elevating the breast while the patient was in recumbent position. The measurement after removal was thirty-nine and one-half inches in circumference, from nipple to pedicle fourteen inches, and around pedicle thirty inches. Its weight was twenty-seven and one-half pounds. On section, the tissues were a grayish-white color, normal in structure.

Dr. F. W. Miller, Interne at the Presbyterian Hospital, made the microscopic examination, and the following report:

"The histologic elements may be considered under two headings, viz.:

"1. Parenchyma elements which are seen as acini

FIG. 1.—Hypertrophy of Mammary Glands. Hamilton's case, 1894.

FIG. 2.—Hypertrophy of Mammary Glands. Hamilton's case, 1894.

and ducts, sometimes greatly compressed so as not to be easily distinguishable. In some the epithelial lining is distinctly columnar, and the lumen of the duct oblong, or large and spherical; in others the epithelial lining, consisting of two layers is made up of small pavement epithelial cells.

"2. The connective tissue elements are in excess of the normal proportion, and consist of highly refractile non-nucleated fiber bundles, taking deep stain with eosin; these fibers interlace in all directions; fat cells are abundant but vessels lacking. Diagnosis: hypertrophy of mammary glands."

There was considerable shock; the patient was well stimulated, external heat applied and the foot

of the bed elevated; she rallied and the wound healed by primary union. On August 11, the wound having healed and the patient being in good condition, the left breast was similarly removed in my clinic at Rush Medical College. The breast had slightly increased in size, contrary to the statement sometimes made that when one breast is removed the other diminishes in size. The operation was attended by no unusual incident and recovery was prompt.

This diffuse form of hypertrophy of the mammary gland is extremely rare. Williams<sup>1</sup> states that "while 2,422 cases of mammary neoplasms came consecutively under treatment at Middlesex, University College, Bartholomew's and St. Thomas Hospitals, during a period of from sixteen to twenty-one years, only six cases of diffuse hypertrophy were seen in the same period." The same author has collected notes of amputations done on sixteen patients, and only one death. "This patient died twenty-two hours after the operation from collapse from excessive hemorrhage during the proceeding."

M. Pierre Delbet<sup>2</sup> says: "Known since the time of Galen, hypertrophy of the breasts is very rare. Velpeau did not observe more than five cases; in 1880 Billroth esteemed it a privilege to have encountered two examples; Labarraque, the author of altogether the best work on this subject, was not able to collect more than thirty-three observations, to which it is necessary to add the more recent cases of Benoit and Monteils (1877), of Monod (1881), Klippel (1887), Billroth (two cases), Barton, Richter, Schussler and Lihotsky."

In conclusion, it is to be mentioned that true hypertrophy (uncomplicated) is usually double, while the cases of hypertrophy of the male breast, described by Leudet (1886) and Blomfield (1886) as an occasional complication of phthisis pulmonalis were unilateral.

## "THE RELATIONS OF MATTER AND MIND."

BY R. E. HAUGHTON, A.D., M.D.

MIDLAND, TEXAS.

Formerly Professor of Surgical Pathology, Operative, and Clinical Surgery, in Central College Physicians and Surgeons, Indianapolis, Ind.; Late Professor of Anatomy, Descriptive and Surgical, in Indiana Medical College, and also Professor of Physiology and Demonstrative Physiology and Anatomy, in College of Physicians and Surgeons, Indiana; Member of American Medical Association, State Medical Association of Texas, Ex-President of Indiana State Medical Association, Honorary Member of Ohio State Medical Association, etc.

### REVIEW.

In reading the article with the above title to its close, I find in the last paragraph this remarkable statement in the form of an interrogatory, viz.: "Do not these converging testimonies focus the truth in the proposition, that the somatic mind of man is (clearly enough) the highest manifestation and legitimate sequence of the primal law of *matter* and *motion* expressed by the Creator in the beginning on the elements of the earth?" The author of this paper paper said in his Presidential address before the AMERICAN MEDICAL ASSOCIATION: "The progress in medicine in the immediate future must be along biologic lines." So in accentuating this thought, I accept the position assumed as to the progress in medicine, but do not accept the final conclusion arrived at in the quotation in the paragraph alluded to. It is to my mind the enunciation of the exploded idea of evolution,

from lower to higher forms, and also involves the doctrine of the "survival of the fittest." It also from the standpoint of investigation ignores the fact of creative design and power in the beginning, in the realm of both matter and mind. It is stated as a proposition by Sterling: "That all organisms consist of the same life matter, which life matter is, for its part due to chemistry, must be pronounced untenable, nor less untenable the materialism founded upon it." The materialism in such a statement is seen when we strip the verbiage from the proposition and present it thus, viz.: That the mind of man is clearly enough the highest manifestation and legitimate sequence of the primal law of matter and motion upon the elements of earth. Motion and matter in their interaction upon each other produce mind. I think it is accepted as true that "like causes produce like results," and that no creature has been produced since the first dawn of creation without sufficient cause.

The opinion that life is a mode or form of energy is one which is gaining an increasing number of adherents among scientific men. Beale, "Protoplasm," page 102: "The idea that life exerts a power over matter—guiding or controlling its actions, having no relation to other forces," is an exploded one, and in this age of free thought and inquiry, ought to require no contradiction. If we follow the lines of the school men they are divided into two classes, viz., vitalists and materialists, and there have been these two classes upon every phase of medical doctrine, as well as upon every other question. Were we to give a more exact division or classification we should say men were divided into materialists and rationalists on the one hand and vitalists on the other.

### THE CREATION OF MATTER.

Forces are the powers which are made to explain the phenomena of vitality. It must have been true that the same forces which give form to a cell as found in a living body, must have been operative when the "worlds were made." These latter belong to the inorganic universe in which there is some unseen power or force which confers life or vitality. True it is, one is microscopic and the others are macroscopic or telescopic, and yet of such vast and wondrous size that we are dumb with wonder and astonishment, and cast about in thought for the power which could create a system of worlds revolving around a common center with such harmony and exactitude. Does it not anticipate the thought which is said, "clearly enough, to be the highest manifestation of and legitimate sequence of the operation of the final law of matter and motion impressed by the Creator in the beginning on the elements of earth?" I am glad he confesses that there is a Creator and that there was a beginning for creation, and this admission stamps out much that is material and irrational in this statement under review. The great First Cause, least understood, is shadowed forth and comes at last upon the scene of the dawn of creation, walking in His majesty upon the wings of the wind, or manifesting Himself as the great I Am, when the rosy hues of the sun's living light first dawned upon the Creator's handiwork, and he said in tones of majesty and power: "Let there be light, and there was light." Why was there light? Because the Infinite and Creative mind had made the sun and hung it out in light and majesty and power, giving heat and warmth and

<sup>1</sup> A monograph on diseases of the breast, London, 1894, p. 82.

<sup>2</sup> Traité de Chirurgie par Duplay et Reclus, t. vi, Art. Mamelle, p. 130.

power to the entire cosmic scene. Which was first? The Creative mind and its fiat, or the worlds? By whose hand were they made, and "without which there was nothing made that was made." Here then we prove that mind, and it matters not as to the fact of the somatic mind of man or the Infinite mind, we thus prove that priority of existence belongs to mind, and that a Divine mind or Creative mind and if so, then according to the law laid down that "like begets like," and like causes produce like results, we have the fact of mind from mind, a Creative mind and a created mind again in the process of creation.

We are told "man was made from the dust of the earth," and God "breathed into his nostrils the breath of life and man became a living soul." Therefore, "when one attempts the analysis of the relation of matter and mind, by any study of it as it exists in the human adult one fails of success most signally." "Because it is not given to men to comprehend infinite questions. How did man become a living soul? By a creative energy, and this is one of the forces of the material universe which has operated upon man ever since and before he had breathed into him the breath of life.

We shall not attempt a review of the processes of the school men in all ages to fathom the processes of human life, or indeed any other manifestation of life. Not even the "modern scientific methods of involved problems." Yet our former neighbor and confrère says: "We must devote ourselves to seeking the simplest form in which the relations of mind and matter exhibits itself and following its development, step by step in its ascending scale until it reaches its maximum in enlightened man." In this question as just stated, I would begin at the reverse end of the scale and passing from higher to lower forms would reach the ultimate limits of the scale in protoplasm conformed to cells, and their almost infinite multiplication as we study their relations in tissues, blood, etc., performing function in all its varieties and uses, with the same system, the same regularity, the same precision as is found to control the globes or cells of more immense and infinite perfections, in what is known as the planetary system. Here is law and order operating in control upon matter, thus revealing the Infinite Intelligence as well as the power which fashioned them by the operation of will, which is known to be the supreme faculty of mind in the inferior orders of creation, dominating the powers of mind as possessed in reason, judgment, affection, etc., so as to accomplish the highest happiness of the individual, when conformed to it.

#### IN THE BEGINNING.

Genesis is simply the beginning, and we are told that "in the beginning God created the heavens and the earth, and the earth was without form and void, and darkness was upon the face of the deep, and the Spirit of God moved upon the face of the waters and God said, Let there be light and there was light." Hence we find in these statements of the book of the beginning (Genesis) the cytogenesis, the morphology, the histology, the anatomy and the physiology of creation in its beginnings (whenever that was), and it does not matter whether it was chronologically 6,000 years, or whether it was according to some data of so-called geologic ages as expressed by Sir Charles Lyell, 35,000 or 50,000 years of our time. It is not so much a question of time as of mind and power or force in

the higher planes of creation; the same law of design, power and creation runs through the entire series. In this historical but brief résumé, the relations of mind and matter are presented to the thoughtful and investigating individual who begins at the top of the scale to comprehend the author, and any attributes which such author may be supposed to possess, and as we must reason, we reason in two directions; from God himself as shown in his works, to his attributes, and when we fail in this direction to comprehend any attributes we look into our own, and thus rising from lower planes and mental characteristics we reach the law that "like produces its like," and thus in form and attribute, as the poet expresses it in his graphic description of man. He says: "In form and moving how express and admirable; in character how like a God." So, too, in the type and forms (cellular) in cytogenesis we see the same admirable and undeviating law that "like produces its like," except when some indefinable and inadvertent influence so operates as to divert the original type into some other form or type which is abnormal to the original type and is not or can not be found in any healthy or normal organism. This may be said to be heterogeneous formation and is the result of some rule or law of morbid production not known in the original type. For illustration: If we take any form of cancer and examine cellular forms we do not find the original type of structure, but some deviation of form and type which is known to us as cancerous formation, varying as the cell forms indicate, so that diagnosis and pathology go hand in hand.

#### GROWTH.

Growth of an organic body involves the question of nutrition, and "nutrition involves the conversion of lifeless pabulum into living germinal matter and comprises several successive steps." (Beale, "Protoplasm," page 102):

"1. The contact of the soluble pabulum with germinal matter.

"2. The separation of the elements of the nutrient substance from the state of combination as pabulum.

"3. The new rearrangement of the elements, and conversion of these into new germinal matter.

"Finally, nutrition, which means growth, is impossible unless living germinal matter be present, and in every case in which it is known to occur new germinal matter is produced." Hence nutrition is a vital process, a living process, and is positive evidence of vitality, and no approach to it has ever been accomplished in the chemic laboratory or in processes which are so-called chemico-vital, and no human ingenuity will ever be able to duplicate the vital relations of living organisms operating under some unchangeable vital force which exists or presides in and over the "germinal matter," which continues under the operation of this force to produce its like, and thus sustain growth upon one side and "metabolism" upon the other, as here are the two sides of life.

#### VITALITY.

Embodied in the term, "germinal matter," it is probable we find the secret of nature's arcana, and the life force is impressed upon it in some such way as the "Spirit of God moved upon the waters," and also when it was said: "Let there be light and there was light." Matter then had been created, and the operative and effective force which was directing the

changes upon the void of the great cosmos was the same intelligent mind and force which has directed the operations of the physical world ever since; no matter what the period of time may have been. So we establish a relation of mind and spirit with the material and spiritual of the universe in which and of which we are a part. It matters but little to the philosopher except he be an evolutionist, or to the scientific physician or scholar except he be a doubter, what particular changes he observes in the modes of mind and force if he but remember,

"One universal purpose through all the ages runs."

And thus on such a basis no cataclysmic results can be found in the realm of mind or matter. There are no results which are not worked out in harmony with divine law and purpose and no

"Eagle's eye or scent of prey,"

but is the result of adaptation and purpose, and hence the biologic result of cells in the construction of the eye and the nerves, with their acute sensibility. Like the bloodhound, which, amid all the traces of others than the one sought, will rapidly follow the right one, without mistake, to the end. Why is it so? First there is the original purpose in the germinal matter, and through cultivation and education the sense and faculty reached its ultimatum in astonishing acuity. So it may be said in the sphere of mind on its cultivation on one subject of thought or practice or another. One becomes a wonderful accountant, and can cast up several columns of figures, and yet can not explain how it is done. So, too, in the musical and poetical world, men and women reach marvelous power and compass in voice, and produce those wonderful instrumental accompaniments of voice, which hold you entranced and bewildered, yet it is by study and practice with the nerve and muscle, one controlling the other in the mechanical execution; yet were it not for the power of assimilation in the germinal cell and membrane, where were the art and practice of music, poetry and song? Where were the touches of Raphael?

#### CONCLUSION.

So we rise in the scale of being, and effort is God's method for this moral and spiritual progress, even up to the idea of a final salvation at the end of a probationary race, to enter into a higher and more spiritual realm which is seen by the eye of faith, "for eye hath not seen nor ear heard the things" nor hath it entered into the heart of man to conceive the things which God has in reservation for those who shall be assimilated to himself in such manner as is presented in the thought of the Bible: "The fatherhood of God and the sonship and brotherhood of the race." This is to my mind the highest evolution of the race, and such an one as he is controlling and directing, not only in this physical universe for man's benefit and development, but will continue it in the future progress and development of such as shall catch the divine purpose, "which through the ceaseless ages runs," in earth and heaven. For these are but parts of the scheme and plan of a divine evolution (mind for material and material for mind) under all the peculiar relations which can or will occur in the evolutionary series. The series here is one in which creative power has had a hand; from the monad to the elephant, from the first cell which originated a human form, to the highest and most intelligent archangel before the throne of God, or may be found

in the lowest or most depraved in the pit of perdition; mind has had to do with matter up to the point and process of translation, when matter drops off by the refining process, and we become like gods, knowing good and departing from evil. This is spiritual evolution, and is also accomplished by the purpose and will of God, operating upon human minds and wills until his purpose be accomplished, either in blessing, or if we will not, in cursing or malediction, or perdition.

Submitted, with no disposition to discussion on the subject, but to put the other side of the question.

### ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 321.)

#### CHAPTER VI.

*Case 8.*—Double pneumonia, bloody sputa, recovery. Robert Hanley; Irishman; came to America in 1846 and has been living in New Orleans since 1847. Weighs 150 pounds; florid complexion, light hair and blue eyes. On Jan. 6, 1877, while working in the hold of a ship, which was very close and hot, was thrown into a great heat and profuse perspiration. Being called suddenly, he left the ship without his coat (his shirt being saturated with perspiration), went on shore and was exposed to a cold wind, and in a few minutes was seized with a severe pain in the left side below the seventh rib. The pain continued to increase on the seventh and eighth, and upon the last day he began to cough and to expectorate thick, bright red sputa. Could not lie on the right side in consequence of the pain and oppression of breathing. On the tenth, eleventh and twelfth the pain and oppression of breathing increased and was attended with high fever. Admitted to Charity Hospital January 12. January 13, A.M., tongue red at tip and edges and furred in the center; sputa thick, brownish-red and streaked with bright blood; high fever, anemia, restless. Respiration labored and attended with sharp pain greatest over region of middle and lower lobes of left lung. Face flushed. Skin bathed in hot perspiration. Upon percussion, dullness amounting to almost complete flatness over middle and lower lobe of left lung and over lower lobe of right lung. Auscultation revealed tubular breathing and crepitant râles upon full inspiration over the regions indicated. The patient was placed upon 2 grains each of quinin and Dover's powder every three hours, and five drops of the tincture of yellow jessamine every two hours. Turpentine stupes were applied over the affected portions of both lungs; milk punch and beef tea ordered in small quantities at regular intervals of two hours. This treatment was continued for several days and the bowels were opened when necessary by the ordinary efferverscing powders. On the 20th there was a marked improvement and the chlorids which had been absent reappeared in the urine and the sputa contained much less blood. Convalescence continued and on the 25th the patient was able to walk about the ward. He was finally restored to health, although he was allowed to remain in the ward for four weeks, until his strength was fully restored. The following table presents the relations of the pulse, respiration and temperature:

Date.	Pulse.		Resp.		Temp.	
	M.	E.	M.	E.	N.	E.
1877						
Jan. 13	109	118	42	40	101.5°	103.2°
" 14	114	104	41	41	103	101.5
" 15	90	100	36	38	101	104
" 16	86	87	30	37	100	101.5

" 25	60	.	20	.	97	.
" 26	82	.	24	.	98.5	.

*Case 9.*—Pneumonia; middle and lower lobes of left lung involved. John Dugan; age 21; native of New Orleans; longshoreman. Has enjoyed good health up to July, 1876, when he suffered with chills and fever. On Dec. 15, 1876, admitted to Charity Hospital with pneumonia and was discharged Jan. 6, 1877. February 21, seized with severe chill, attended with cough, high fever and severe pain in left side. Admitted to Charity Hospital February 25; high fever, rapid pulse and respiration; tongue red at tip and edges and furred in center; middle and lower lobes of left lung dull upon percussion, with tubular breathing and crepitant râles; chlorids absent from urine; sputa thick and rusty colored. The treatment was similar to that instituted in the preceding case; namely, quinin and Dover's powder, tincture of yellow jessamine, turpentine stupes, milk punch and beef tea. The results were favorable. February 27, oppression of breathing and pain in left side diminished; February 28, free from pain, although left side still dull upon percussion; sputa still mixed with blood; small quantity of chlorids in urine. Continued to improve up to March 3, the expectoration being quite copious, with progressive diminution of dullness; reappearance of crepitant, subcrepitant and mucous râles over the affected portions of the left lung. March 3, the temperature and pulse were normal and patient able to sit up with good appetite. Recovery rapid and complete. The following observations were recorded:

Date.	Pulse.		Resp.		Temp.	
	M.	E.	M.	E.	M.	E.
1877						
Feb. 26	120	108	40	36	103 °	102 °
" 27	94	105	28	44	99	101
" 28	80	86	28	37	98	101
Mch. 1	78	77	26	28	98.2	99
" 2	72	76	22	28	98	98.2
" 3	72	73	24	24	98	98.2

It is evident that in the preceding cases of pneumonia, the combined use of quinin, Dover's powder and tincture of yellow jessamine reduced the frequency of the pulse, diminished the temperature and promoted the arrest and resolution of the pneumonic inflammation.

*Case 10.*—Pneumonia of right lung, engrafted on malarial fever. John C. Keller; age 24 years; admitted to Charity Hospital Feb. 4, 1874. Occupation, clerk. Seized with a severe chill January 30, followed by high fever. Middle lobe of right lung in second stage of pneumonic inflammation; lower lobe of left lung in similar condition. February 4, evening temperature of axilla 104.8 degrees. February 5, morning, respiration 36, pulse 126, temperature 103; evening temperature 105. Suffers from a painful cough and oppression of breathing; sleep disturbed; skin dry and hot; tongue red at tip and edges and coated heavily with yellow fur. Sputa abundant and mixed with considerable quantities of blood. February 6, morning, respiration 38, pulse 118, temperature 104.8; evening temperature 105.3. February 7, morning, respiration 39, pulse 128, temperature 104.1. This day the patient had a profuse hemorrhage from his lungs and his stools also contained blood. The hemorrhage was attended with a marked depression of temperature, as is often the case in the black vomit (hemorrhage from the stomach) in yellow fever. February 8, morning, respiration 37, pulse 121, temperature 103; evening temperature 101.5. February 9, morning, respiration 38, pulse 125, temperature 101.8; evening temperature 101.6. February 10, morning, respiration 34, pulse 108, temperature 101.2; evening temperature 103.2. February 11, morning, respiration 34, pulse 104, temperature 102; evening temperature 102.6. February 12, respiration 30, pulse 101, temperature 101.5; evening temperature 101.3. February 13, morning, respiration 32, pulse 120, temperature 100; evening temperature 102. February 14, respiration 32, pulse 96, temperature 100. February 15, morning temperature 98.9; evening, 100.8. The patient continued to improve and was discharged March 3.

It is worthy of note that in this case of pneumonia, hemorrhage from the lungs was attended, as in cases of hemorrhage from the stomach and bowels in yellow fever, with a decided reduction of temperature, and also that the loss of blood from the lungs in this case appeared to be productive of good and to mark the period of convalescence.

*Case 11.*—Pleuro-pneumonia, solidification of entire lung,

death. I. D., age 28; entered Charity Hospital Feb. 19, 1874. February 20, morning, respiration 36, pulse 108, temperature 102; evening temperature 102.7. February 21, respiration 26, pulse 95, temperature 103. February 22, respiration 39, pulse 104, temperature 102.7. February 23, respiration 39, pulse 115, temperature 103.5. February 24, respiration 40, pulse 120, temperature 102.5. February 25, respiration 38, pulse 114, temperature 97. This patient died on the night of the 25th. Entire right lung solidified, as shown by post-mortem examination. Great capillary congestion before death.

*Case 12.*—Abscess of lungs, following double pneumonia. A. R., age 26; admitted into Charity Hospital with pneumonia (double) Nov. 20, 1873. During the active stages of the pneumonic inflammation the temperature of the axilla reached 109 degrees F.; the pulse ranged from 100 to 130, and the respiration from 50 to 58 per minute. A large portion of the right lung passed into the stage of solidification and gray hepatization, and a large cavity formed in the middle lobe of the right lung; the patient was not restored to health until the end of four months. During the period in which these changes were taking place in the lungs, daily observations were made upon the pulse, respiration and temperature, numbering over seven hundred. During a period of one hundred and twenty days, while structural alterations were taking place in the lungs the pulse ranged from 80 to 130; the respiration from 22 to 40, and the temperature of the axilla in the morning from 99 to 102 degrees F., and in the evening from 100 to 104 degrees F.

*Case 13.*—Pneumonia engrafted on malarial fever. P. W., age 33; entered Charity Hospital Dec. 11, 1873. Had suffered with chills and fever for one week before entering the hospital. Lower lobes of both lungs involved on the 12th. During fourteen days the active stages of the disease, the morning temperatures ranged from 101.5 to 105 degrees, and the evening temperatures from 103 to 106 degrees. On the fifteenth day there was a distinct remission of the fever, which rose again on the seventeenth day, declined on the eighteenth to twenty-fourth days. On the twenty-fifth, the temperature again rose, apparently from the supervention of a fresh paroxysm and the involvement of other portions of the pulmonary tissues in the pneumonic inflammation. In this which was the last paroxysm and followed by convalescence the axillary temperature reached 104 degrees. The pulse in this case ranged from 72 to 120; and the respiration from 24 to 40 per minute.

*Case 14.*—Double pneumonia. Michael Castello; age 30; entered Charity Hospital Jan. 13, 1874. Had chills and fever two days before entering hospital. January 15, delirious. Region of left lung dull upon percussion, with crepitant and subcrepitant râles. Lower lobe of right lung dull upon percussion with crepitant râles, oppressed breathing with severe cutting pains. Tongue red at tip and edges and coated with yellowish fur in center. Urine high colored; specific gravity 1022; strong acid reaction, and mere trace of chlorids; no albumen. Morning, pulse 120, respiration 25, temperature 105.2 degrees; evening, temperature 105 degrees. January 16, delirious; increased dullness over left lung and lower lobe of right lung, with tubular breathing, bronchophony and increased vocal resonance. Specific gravity of urine 1025; high colored; strong acid reaction; absence of chlorids; no albumen. Morning, pulse 114, respiration 32, temperature 104 degrees; evening, temperature 105 degrees. January 17, morning, pulse 114, respiration 32, temperature 104 degrees; evening, 104.2. Trace of chlorids in urine. January 18, morning, pulse 124, respiration 40, temperature 103.5 degrees; evening, temperature 103.5 degrees. Trace of chlorids in urine. January 19, morning, pulse 114, respiration 32, temperature 101.5 degrees. Trace of chlorids in urine. There has been a marked decline of temperature, the pulse and respiration are also less frequent, and the delirium is disappearing. January 20, morning, pulse 98, respiration 26, temperature 99.5; evening 100.6 degrees. While the physical signs show no marked change, the urine shows a marked increase of the chlorids, the temperature has declined and the circulation and respiration are slower and more natural. The delirium has disappeared and the patient shows signs of marked improvement. January 21, continues to improve. Morning, pulse 84, respiration 28, temperature 98.5; evening, 99.8. Chlorids increasing in urine. January 22, morning, pulse 80, respiration 24, temperature 98.4. January 23, continues to improve; the air is again entering the solidified portions of the lungs and there is a great increase of the chlorids in the urine. Morning, pulse 66, respiration 24, temperature 97.5; evening, temperature 99.2. January 24, pulse 70, respiration 20, temperature 99.2;

evening, temperature 100.3. Specific gravity of urine 1022. Chlorids abundant. January 25, morning, pulse 74, respiration 22, temperature 98.4; evening, temperature 99.6. January 26, morning, pulse 72, respiration 20, temperature 98; evening, 98.7. January 27, morning, pulse 76, respiration 20, temperature 98.4; evening, temperature 101.1. Continued to improve and on the 28th was able to dress and come down to amphitheater.

*Case 15.*—Pleuro-pneumonia of left lung, recovery. L. Winans; age 30; native of Ohio; on the trip from St. Louis to New Orleans was seized with severe chill followed by diarrhea and pain in left side. Entered Charity Hospital, ward 27, Jan. 3, 1874. Face flushed, frequent and painful cough, rusty colored pneumonic sputa, dullness over lower portion of left lung, bronchophony, bronchial respiration, increased local fremitus, vesicular murmur heard only in clavicular region of left lung, some pleuritic pain in left side, hot dry skin, dry red tongue, thirsty, loss of appetite and restlessness. Morning, pulse 110; respiration 28; temperature 104. The treatment which I described at length in the article on "Pneumonia," vol. I, "Medical and Surgical Memoirs," was instituted. Three and a half grains each of quinin and Dover's powder were administered every four hours, and 4 drops of the tincture of veratrum virid, every four hours, alternating with the powders of quinin and ipecac et opii, turpentine stupes applied over region of affected lungs. Beef tea and milk punch freely administered. Mere trace of chlorids in urine. January 4, morning, pulse 104, respiration 28, temperature 102. The quinin and Dover's powders and veratrum appear to have effected a decided reduction in the temperature, although patient is restless and anxious, and complains of some pain in the left side. January 5, morning, pulse 80, temperature 100.4, respiration 28. No chlorids in urine, specific gravity 1018, strong acid reaction, bowels moved, no albumen in urine. Evening, temperature 100.2. January 6, temperature still depressed, trace of chlorids in urine; substituted tincture of yellow jessamine 10 drops every four hours for the tincture of veratrum. Morning, pulse 94, respiration 32, temperature 102.5. Evening, temperature 105.5. January 7, left lung completely solidified, sputa abundant and rusty colored. Morning, pulse 112, respiration 32, temperature 104.4. Evening, temperature 103.5. January 8, pulse 100, respiration 36, temperature 102.5. Evening, temperature 103.5. January 9, morning, pulse 104, respiration 30, temperature 100.2. Evening, temperature 102. January 10, pulse 80, respiration 26, temperature 98.9. Evening, temperature 99. January 11, morning, pulse 80, respiration 26, temperature 98.2. Evening, temperature 99. Chlorids reappear in urine, specific gravity 1018, no albumen has appeared in the urine up to the present time. January 12, morning, pulse 78, respiration 26, temperature 98.5. Evening, temperature 98.8. On this day chlorids reappeared in the urine, continued to improve and was discharged cured.

*Case 16.*—Pneumonia. Michael Burk; age 22; native of Germany; laborer. Entered Charity Hospital Jan. 12, 1874. Was taken with a chill followed by a high and continued fever four days before entering the hospital. January 13, great pain in left side, hot dry skin, dullness over left lung, bronchophony and increased local fremitus with tubular breathing. Morning, pulse 120, respiration 52, temperature 101.3. January 14, patient complains of great pain in left side and lower portion of right lung, which is dull upon percussion, rusty colored sputa. Morning, pulse 118, respiration 50, temperature 104.5. Quinin and Dover's powder, three grains of each every three hours administered internally. Tablespoonful of official solution of acetate of ammonia every four hours. Turpentine stupes to chest. Beef tea and milk punch. January 15, rested badly during night, delirious, tubular breathing and dullness upon percussion over left lung, dullness upon percussion over lower portion of right lung. Morning, pulse 112, respiration 56, temperature 102. January 16, very restless, delirious, physical signs the same, absence of chlorids in urine, no albumen in urine. Morning, pulse 104, respiration 48, temperature 102.6. January 17, delirious, necessary to confine patient to the bed, no chlorids in the urine, trace of albumen in urine. Morning, pulse 124, respiration 64, temperature 103.5. January 18, wild delirium, was held in bed all night by nurses, albumen in abundance in urine but no chlorids. Morning, pulse 120, respiration 64, temperature 103.5. Evening, temperature 105. January 18, patient more quiet, albumen not so abundant in urine, chlorids absent. Morning, pulse 132, respiration 62, temperature 104. Evening 104.3. January 20, patient in semi-conscious state, traces of albumen in urine, no chlorids. Morning, pulse 112, respiration 64, temperature

103. Evening 104.5. Alcoholic stimulants have been freely given. January 21, no delirium, rested well during the night, some appetite, albumen disappearing from the urine, chlorids returning, expectoration more free. Morning, pulse, 90, respiration 36, temperature 101.9. Evening, temperature 102. Convalescence was slow in this case. The patient sat up for the first time about February 2. The temperature remained elevated until February 10; it reached 103 on this and for a period of twenty-two days, from January 21 to February 10 ranged in the morning from 101 to 103, and in the evening from 101 to 104. Pulse from 90 to 140, and respiration from 32 to 58 per minute. Recovery tedious but satisfactory.

*Case 17.*—Double pneumonia, death. Peter Wonts, age 27. Entered Charity Hospital Dec. 18, 1874; pneumonic inflammation of lower lobes of both lungs, great oppression in breathing, purple lips and extremities, delirium. The morning temperatures ranged from 97.5 to 102; and the evening temperatures from 100 to 105.5, pulse from 96 to 120, respiration from 25 to 35. This patient died on the tenth day after entering the hospital.

*Case 18.*—Pleuritis. T. Lynch, age 21, native of Ireland; entered Charity Hospital Dec. 20, 1873. Had been treated in this institution two weeks before, for intermittent fever. December 20, evening. Intense pain in right side, dullness upon percussion of right lung with friction, pleuritic sounds in respiration. Pulse 130, respiration 25, temperature, axilla 105. December 21. Pain in side intense, morning pulse 77, respiration 23, temperature 101. Evening pulse 110, respiration 23, temperature 106. The patient has been treated with quinin and Dover's powders,  $3\frac{1}{2}$  grs. of last every three hours, and turpentine stupes to chest, these measures appeared to be beneficial and to rapidly reduce the temperature. December 22. Morning, pulse 76, respiration 30, temperature 99; evening, pulse 80, respiration 30, temperature 100. At 3 p.m. on the preceding day the patient had a severe chill followed by high fever in which the temperature reached 106. A large plaster was applied to the side, quinin freely administered with beneficial results as stated. December 23, slept better during the night, improving, pain in side much relieved. Morning, pulse 72, respiration 25, temperature 99; evening, pulse 80, respiration 28, temperature 101. December 24. Morning, pulse 86, respiration 32, temperature 100; evening, pulse 82, respiration 30, temperature 102. December 25. Morning, pulse 75, respiration 28, temperature 99.5; evening, pulse 83, respiration 30, temperature 101. December 26. Morning, pulse 70, respiration 20, temperature 99; evening, pulse 75, respiration 24, temperature 100. The patient continued to improve and was discharged in a few days after this observation.

*Case 19.*—Pneumonia. Supervening on malarial fever, cured. N. T., aged 24, entered Charity Hospital Jan. 6, 1874. Arrived in New Orleans in destitute condition and slept on levee nights and January 5 had a violent chill followed by congestion of lower lobes of both lungs and high temperature, 106.2, pulse 120, respiration 38. Under the action of the quinin and Dover's powders, rapid reduction of temperature and improvement of symptoms.

*Case 20.*—Typhoid fever. T. P., entered Charity Hospital Jan. 11, 1874, rapid pulse, high temperature, great nervous prostration, muttering delirium. During a period of thirty-two days the temperature oscillated between 99 and 106. The temperature in the morning varied from 1 to 7 degrees lower than the evening temperature. On January 12, (second day after entrance) the morning temperature was 104 and the evening temperature 105. On January 23 the morning temperature was 99 and the evening 106; on the 28th morning temperature 100, evening 103; the 30th, morning temperature 102, evening 105. The pulse ranged from 90 to 110, respiration from 30 to 56.

*Case 21.*—Typhoid fever. H. F., age 27. Entered Charity Hospital November 29, high fever continued from November 29 to December 21. The range of the temperature and pulse are as follows: November 29, evening, pulse 102, temperature 105. 30th, morning, pulse 86, temperature 103; evening, pulse 94, temperature 105. December 1, morning, pulse 82, temperature 103; evening, pulse 90, temperature 105. 2d, morning, pulse 80, temperature 103; evening, pulse 82, temperature 103.5. 3d, morning, pulse 86, temperature 103.5; evening, pulse 90, temperature 104.5. 4th, morning, pulse 90, temperature 103; evening, pulse 86, temperature 104.5. 5th, morning, pulse 82, temperature 101; evening, pulse 88, temperature 103.4. 6th, morning, pulse 80, temperature 101; evening, pulse 88, temperature 103. 7th, morning, pulse 100, temperature 104; evening, pulse 94, temperature 104. 8th, morning, pulse 82, temperature 99; evening, pulse

104, temperature 105. 9th, morning, pulse 90, temperature 112.5; evening, pulse 88, temperature 104. 10th, morning, pulse 82, temperature 100.5; evening, pulse 104, temperature 104. 11th, morning, pulse 90, temperature 100.5; evening, pulse 88, temperature 104.5. 12th, morning, pulse 108, temperature 100; evening, pulse 94, temperature 104. 13th, morning, pulse 86, temperature 103; evening, pulse 80, temperature 101. 14th, morning, pulse 84, temperature 100; evening, pulse 80, temperature 100. 15th, morning, pulse 80, temperature 99.5; evening, pulse 80, temperature 100.3. 16th, morning, pulse 90, temperature 98.8; evening, pulse 80, temperature 100.2. 17th, morning, pulse 86, temperature 98.5; evening, pulse 80, temperature 100. 18th, morning, pulse 80, temperature 99.5; evening, pulse 120, temperature 103.6. 19th, morning, pulse 110, temperature 102; evening, pulse 100, temperature 103. 20th, morning, pulse 96, temperature 101.5; evening, pulse 92, temperature 100.5. After this date the temperature gradually descended to the normal state and the bowels became constipated.

*Case 22.*—Typhoid fever. John Martin, age 24, entered Charity Hospital November 21. In this case the diarrhea and fever continued for a period of forty-four days. The morning temperature ranged during this period between 98 and 105, and the evening temperature between 98.5 and 105 degrees F. The pulse ranged from 70 to 120; the respirations from 24 to 34 per minute.

*Case 23.*—Albuminuria and malarial fever. J. P. Banem; age 30; admitted to Charity Hospital Jan. 20, 1874. Has been living on the banks of the Mississippi River, where he contracted intermittent fever, from which he has suffered during the past three months. The condition of the patient is as follows: Great anemia; tongue swollen, indented by the teeth along the edges, pale, flabby and tremulous; complexion sallow and of a waxlike greenish tinge; features swollen; abdomen distended with fluid; lower extremities swollen; complains of headache and dullness of intellect; urine high colored and scant, and loaded with albumen. This patient was kept under observation for about three months (ninety days), and at various periods the urine contained blood corpuscles in addition to the albumen and urinary casts. The treatment consisted mainly in keeping the bowels open by means of saline purgatives, the occasional use of quinin for several consecutive days, and the administration of diuretics and alteratives, among which may be mentioned iodid of potassium combined with wine of colchicum and syrup of squills. The strength was maintained by nutritious diet and the preparations of iron. Under these measures the improvement was gradual and decided; the dropsical effusion disappeared and the patient was discharged at his own request in April.

In this case the action of the heart was quick and irritable; no valvular disease, however, was detected. Edema of the lungs was a troublesome symptom. The pulse was rapid and irritable, varying from 100 to 130; the respiration was often embarrassed and ranged from 20 to 30; the temperature in the morning ranged from 97.5 to 100, and in the evening from 99 to 101. This case appears to have been dependent to a great extent upon the action of malaria.

*Case 24.*—Constitutional syphilis. R. N. W., age 49½ years. Entered Charity Hospital Dec. 12, 1873. Contracted syphilis in 1866; suffers with severe pains in the extremities and head which increase greatly during the night and destroy his rest. December 17, morning, temperature 99.6, pulse 80, respiration 20; evening, temperature 100.6. 18th, morning, temperature 98.5; pulse 80, respiration 18; evening, temperature 100. 19th, morning, temperature 98.5, pulse 96, respiration 24; evening, temperature 100. The observations upon the temperature and pulse were continued for a considerable length of time, and the former ranged from 98 Fah. in the morning to 101 in the evening and the latter from 80 to 100.

*Case 25.*—Cirrhosis of liver; ascites; dysentery and diarrhea. T. G., age 50; native of Cincinnati, Ohio. Entered Charity Hospital March 4, 1874. Has been a hard drinker for twenty-two years. Had malarial fever in July, 1873. Has lost flesh, his weight decreasing from 154 to 123 pounds. Abdomen distended with liquid; lower extremities edematous; bowels very loose. In this case the temperature in the axilla varied in the morning from 98.5 Fah. to 99.5; and in the evening from 99 to 100.5; the pulse varied from 70 to 90 per minute.

*Case 26.*—Aneurysm of the arch and descending portions of the aorta. L. D.; age 43; native of Ireland; has lived in

America twenty years; served in the Confederate Army about twelve months. Laborer. Entered Charity Hospital March 4, 1874. States that about one month before entering the hospital, while rolling a bale of cotton, felt a sudden pain in the abdominal region and upon examination found a small tumor which has been steadily increasing from that date, and at times interferes with his respiration. The second sound of the heart is accompanied by a distinct aortic murmur and the pulse is irregular and at times dicrotic. The temperature in this case ranged from 98.4 Fah. to 101.3, and the pulse from 80 to 90.

*Case 27.*—Aneurysm of arch of aorta and phthisis pulmonalis. Nicholas Batterton; age 33 years. Admitted into Charity Hospital Dec. 1, 1873. Patient says that he has been sick for one year and that the disease began with pneumonia. His brother died with phthisis. After the attack of pneumonia, suffered with a troublesome cough, and has had hemorrhage from the lungs seven times. The arch of the aorta is dilated and the tumor is evident in the supra-clavicular region, where the pulsation can be seen and also readily felt. When the fingers are pressed above the superior border of the sternum, downward and backward, the round pulsating contour of the aneurysm is distinctly felt. Observations were continued in this case, for one hundred and twenty days, and during this period the pulse varied from 60 to 100, the respiration from 30 to 40 per minute, the temperature in the morning from 99 to 101, and in the evening from 100.3 to 103.5. Auscultation revealed a distinct diastolic mitral murmur, propagated along ascending aorta and along the arch. Upon cod-liver oil and syrup of the hypophosphites, this patient continued much in the same state, until the winter of 1874, when the emaciation became more rapid and the patient died Nov. 2, 1874. Death in this case was in no manner attributable to the aneurysm of the aorta.

*Case 28.*—Abscess of thigh and extensive bed sores resulting from yellow fever. E. Scheiss; age 37; native of Germany. Entered Charity Hospital Oct. 29, 1873. Had been sick with yellow fever several days before entrance. Attack severe attended with high fever, vomiting and intense jaundice. During the period of convalescence and calm, a swelling was observed in left leg which greatly increased. From the confinement and also from the deranged state of the fluids caused by the yellow fever poison, large bed sores formed upon sacrum and hips. A large abscess of the thigh was opened. Patient died from exhaustion induced by hectic fever February 24. During 140 days following the active stage of the yellow fever the temperature ranged from 100 to 105.2; the evening temperature ranged from 101.5 to 105.2. The pulse varied from 100 to 140 and the respiration from 24 to 34.

*Case 29.*—Mitral regurgitation, hypertrophy and dilatation of heart, and Bright's disease. R. Maney; age 36. Admitted to Charity Hospital Jan. 29, 1874. Had yellow fever in 1854 and 1858; contracted syphilis in 1864; suffered with rheumatism in 1869; malarial fever in 1871 on Red River. In August, 1873, feet began to swell, the liver was enlarged and the action of the heart irregular. Urine loaded with albumen. Owing to the obstruction to the circulation the patient suffered with the symptoms of edema of the lungs, accompanied with bloody expectoration, ascites and anasarca. In this case the pulse varied from 52 to 120; respiration from 20 to 28; temperature from 98 to 102.2. The temperature attained the highest point in the evening of February 5. The reduction of the pulse to 52 beats per minute was due to the action of digitalis.

A comparison of the results recorded illustrating the changes of the pulse, respiration and temperature in various diseases with those of yellow fever, establishes the following conclusions:

1. Yellow fever is a distinct specific disease.
2. Yellow fever is distinguished from other diseases by the frequency of the occurrence of black vomit and jaundice, and the progressive diminution of the frequency of the pulse after the establishment of the maximum temperature, also the want of correspondence observed in many cases between the rapidity of the respiration and the action of the heart.

3. As a general rule in acute diseases, the rapidity of the action of the heart corresponds with the rapidity of the respiration; but in some cases of yellow fever in which the respiration is increased fourfold, the pulse actually beats less rapidly than in health.

4. Yellow fever is a continued form of a single paroxysm, in which a powerful depressing effect is evidenced upon the action of the heart. The cause of the depressed action of the heart will be discussed in the following chapter relating to the changes of the blood.

5. If the thermometric changes of yellow fever be projected as in the form of charts, and if a comparison be instituted with the thermometric changes in other diseases, it will be observed that those of the former disease more nearly resemble the rapid rise and sudden fall of temperature observed in varioloid without secondary fever, mild scarlatina, and simple uncomplicated pneumonia which runs its course without fresh accessions of inflammatory action; while on the other hand, they differ materially from the rapid and oft recurring elevations and depressions of temperature characteristic of the various forms of paroxysmal malarial fever.

6. The cause of the rapid rise and declension of the temperature in yellow fever must be sought chiefly in the changes induced in the blood and in those organs upon which the circulation and integrity of the blood depends. Neither the rapid rise nor the sudden declension of the temperature can be referred wholly to the effects of the yellow fever poison upon the nervous system.

While it must be admitted that the experiments of Chossat, Sir Richard Brodie, H. Nasse, Claude Bernard, Brown-Séguard, Budgé, Waller, De Ruyter, Schiff, Naunyn and Quincke, and the experiments of Tscheshichim, in which division of the medulla oblongata near its junction with the pons, caused a remarkable elevation of temperature from 102.92 to 108.68 Fah. and finally convulsions and death; and a large number of pathologic observations, in which most remarkable elevations and variations of temperature accompany profound alterations and disturbances of the nervous system, without corresponding changes in the respiration and circulation, sustain the theory of centers of control which have their seat in the brain, and which regulate the activity of the spinal cord, (when they are destroyed, the activity of the spinal cord being morbidly increased, as manifested by increased reflex action, quickened respiration, acceleration of the cardiac systole, and increased animal heat), and that a great part of the pathologic phenomena of warmth may be only the expression of the action of the vasomotor nerves, and still farther that the integrity of certain parts of the central nervous apparatus is more necessary for the regulation of animal heat than that of any other part of the body; on the other hand, Breuer and Chrobok, after an investigation of the question, whether the nerves of a part supply the stimulus which causes the febrile elevation of temperature in an inflamed part, by means of experiments on animals in whom they have as far as possible divided all the nerves of one part of the body, think themselves justified in concluding that the fever of the traumatic inflammation is independent of the nervous connections of the inflamed part, with the nerve centers; and by an extended series of observations, (see note) I have established the fact that in hospital gangrene and pyemia, the elevations of temperature are independent of the local lesions of the structures, and are

coincident with the introduction of the gangrenous and pyemic poisons into the blood, and the changes of temperature are intimately associated with the changes of the blood and urine, and are invariably accompanied by increased amounts of such constituents as urea, phosphoric and sulphuric acids, which result from the chemic changes of the solids and fluids of the body; and even the traumatic fever accompanying gunshot wounds arises from the introduction of inflammatory products into the blood, and depends not so much upon the extent and nature of the wounds as upon the state of the solids and fluids at the time of the reception of the injury, and upon the character of the inflammatory products absorbed into the circulatory fluid. Even in such inflammatory diseases as pneumonia, attended with extensive tissue change, the introduction of certain organic products into the blood must be active to a greater or less extent in the production of high temperatures.

It is well known that some of the most violent poisons, during their direct action upon the nervous system, are unattended with elevations of temperature; while on the other hand putrid matter, pus and certain animal secretions, as the poison of the rattlesnake and copperhead of this country, induce profound alterations in the constitution of the blood, attended with the most marked variations of temperature; and in the action of the latter class of poisons, the phenomena appear to be akin to the changes which may be induced by ferments, which are not only capable of increasing the amount of heat, but may be limited in their action, or in the amount and character of the changes which they induce in virtue of their chemic constitution and that of the blood or medium in which they are active.

It is well established that certain substances as woorara, coffee, musk and camphor, and putrid fluids, have a direct effect in raising the temperature after their entrance into the circulation.

Voisin and Lionville, by means of subcutaneous injections of woorara, induced a complete artificial fever in human beings, with rigors, heats and sweatings, the temperature rising to 104.8 F., accompanied with all the signs of febrile circulation and secretion and disturbance of the nervous system.

The effects of certain animal substances in elevating the temperature, when injected into the blood, have been shown by the experiments of Billroth, Hufschmidt, O. Weber, Fresse and others. When the putrid solutions or pus are injected in the blood, the temperature rises considerably even within two hours after injection, and reaches its maximum in from two to twenty-eight hours; after a single injection a rapid defervescence generally sets in, shortly after the acme has been reached; while on the other hand, after repeated injections, death constantly occurred generally with high temperatures. Fluids from inflamed tissues, pyemic and septicemic blood, and even the blood of an animal merely suffering from simple inflammatory fever, or from other kinds of fever, produced similar deviations of temperature.

Fresse has determined by experiments, that the rise of temperature induced by the introduction into the blood of the products of decomposition, and of inflammatory tissue destruction, do not depend upon the pus corpuscles, nor upon the so-called germinal matter, which according to some, are such powerful and essential agents in the production of inflammatory diseases, but upon the serum of the fluid;

NOTE.—Investigations upon the Nature, Causes and Treatment of Hospital Gangrene, as it prevailed in the Confederate Armies, 1861-1865, by Joseph Jones, M.D. Surgical Memoirs United States Sanitary Commission, vol. II, pp. 146-570.

even boiling and subsequent filtration does not destroy the property; and that the removal of the fibrin and even the filtration of the blood of animals suffering from fever, do not deprive it of the pyrogenic effects when injected into the living circulating blood.

The unknown cause which excites the specific morbid process of yellow fever would appear to have something in common with the action of such putrid animal substances, when introduced into the blood; and the fact is worthy of careful consideration that the property possessed by such matters, of exciting chemic change and elevation of temperature, was not destroyed by boiling and subsequent filtration of the putrid matters, for we have thus a clear demonstration that the animalculæ, vegetable or germinal theories, as to the origin of yellow fever, are not *absolutely necessary* to the explanation of the febrile phenomena.

Neither the rapid rise nor the sudden declension of the temperature in yellow fever, therefore, are *necessarily* referable *solely* to the effects of the poison upon the nervous system; because, in the first place, the changes of the blood are among the first manifestations of diseased action, and the progress and termination of each case is largely dependent upon the extent and character of the changes of the blood and the degree of elevation of the temperature; in the second place, the sudden fall of the temperature during the succeeding stage of calm may be referred to the peculiarity of the self-limited chemic changes excited by the poison, and to the structural alterations induced in the muscular tissue of the heart and in the liver and kidneys, and the sedative action of the bile, urea and other excrementitious products retained in the blood upon the nervous system; and finally, in the third place, the changes of the blood and of the heart, liver and kidneys are of a definite physical and chemical nature and could never be induced by a mere exaltation or depression of nervous action, and must be referred to the introduction and action of some agent or material, related in a definite manner in its chemical constitution and physical properties, to the fluids and solids in which it induces these profound physical and chemical changes.

Without doubt, the action of the yellow fever poison upon the nervous system may be indirect and of the most important character; but the best established facts do not justify us in locating the origin of the disease wholly in the action of the poison upon the nervous system, and in fact the earliest sensible manifestations of disordered nervous action, as evidenced in unconsciousness, loss of appetite and chilly sensations may be entirely secondary to the changes in the blood, by which all parts of the nervous system are surrounded and supplied.

It must, however, be admitted that in the present state of our knowledge it is impossible to refer the elevations and depressions of temperature in yellow fever, with certainty to either the decrease or increase of any one constituent of the blood; for M. Andral has shown that when the blood contains more than .004 of fibrin the temperature rises, and in a corresponding ratio. Thus of all diseases, pneumonia is marked with the greatest increase of fibrin, and is the highest in temperature of all the phlegmasiæ; in eighty-five cases, in only thirteen was the temperature below 39 degrees C. (102.2 degrees F.), in forty-four it was between 39 and 40 degrees C. (102.2 and

104 degrees F.) in twenty-six below 40 degrees C. (104 degrees F.) and 41 degrees C. (105.8 degrees F.); and in two rose to 41.2 degrees C. (106.16 degrees F.). In acute pleurisy, in which there is always less fibrin, the temperature only once reached 41 degrees C. (105.8 F.) and usually oscillated between 38.5 degrees C. (101.3 F.) and 39.5 degrees C. (103.1 degrees F.). M. Andral, however, records exceptions to this relationship of the increase of fibrin and the elevation of temperature in inflammatory diseases, as in erysipelas, when there have been only .007 of fibrin, the temperature has been 41.8 degrees C. (107.24 degrees F.); and he very justly does not consider the increase of fibrin and the rise of temperature as cause and effect; for in the pyrexia, when there is no excess of fibrin, but rather a diminution of this constituent, the temperature is as high or higher than in the phlegmasiæ; thus 42.4 C. degrees (108.32 degrees F.) have been reached in typhoid fever; 42 degrees C. (107.6 degrees F.) in the event of smallpox, the last stage of ague and in glanders, etc. Indeed, the highest degrees are reached in diseases where there is the least fibrin in the blood. (See note.) Neither do the number of red globules affect the rise of temperature to an appreciable degree in inflammations and fevers, as I have carefully determined by comparison of the constitution of the blood, with the elevations of temperature in various diseases.

## SOCIETY PROCEEDINGS.

### Proceedings of the First Meeting of the American Academy of Railway Surgeons.

Held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.

(Continued from page 327.)

### COMPARATIVE VALUE OF PLASTER-OF-PARIS AND SILICATE OF SODA, AS A DRESSING FOR FRACTURES.

BY MILTON JAY, M.D.

CHIEF SURGEON, C. & E. I. RY, CHICAGO, ILL.

Plaster-of-Paris, and silicate of soda are both valuable agents in the treatment of fractures, when skillfully used by the experienced surgeon; and we soon become so familiar with the use of such common agents as these that we are likely to imagine that any one can readily and in a proper manner apply either of these bandages to any and all kinds of fractured limbs. But because of the careless manner and unscientific way in which inexperienced persons use either the plaster-of-Paris or silicate of soda in the treatment of fractures many failures and results that are not satisfactory are recorded. The first question should always be, *Do we know how to use any agent or instrument successfully before we condemn it?* It may be a failure in our hands, and yet a success in the hands of one experienced. It will not do to condemn or extol an agent or instrument as being good or bad upon a single trial, or upon the authority of a single person; it may require experience to enable a good surgeon to discover the good or bad qualities of an agent, instrument or appliance. I have more than once attempted to use an instrument or surgical device (with which I was not familiar) denounced it as worthless and laid it aside but after seeing it used by an experienced hand it appeared to be perfect. I have tried again and succeeded, came to the conclusion that it was just the thing, I had learned how to use it. This same rule holds good in the application of bandages in cases of fractures. *No one splint or one kind of bandage will do for all kinds of fractures.* Different kinds of fractures, as well as fractures of the same kind in different parts of the body, require a splint or bandage well adapted to each individual case.

I am satisfied that the plaster-of-Paris splint when properly applied will fill more indications and be applicable to

more kinds and a greater variety of fractures than any one agent in surgical use. The silicate of soda (or liquid glass, as it is sometimes called) is clean, neat, and very fine for small bones. It is easily applied and makes a beautifully light splint or fracture dressing; there is nothing untidy or unclean about it, hence as a dressing for the fastidious, who insist on having everything neat and clean, whether sick or well, this is a very desirable dressing for the smaller bones. But as an agent that is to be used in the treatment of fractures generally, it will not compare favorably with the plaster-of-Paris, which will set or become firm and permanently fixed much sooner than silicate of soda, which dries very slowly and requires a long wait before it becomes firm. In compound fractures, or where an opening is necessary to treat a flesh wound, the plaster-of-Paris is the preferable bandage. One can also succeed better with the plaster-of-Paris, when the surface is irregular or uneven, or where a joint must be included in the bandage. In all cases of railroad fractures except it be of the fingers, you will succeed best with plaster-of-Paris. In fractures of the femur in upper third when it is necessary, in order to fix the short fragment, to include the pelvis as well as the leg in the bandage, the plaster-of-Paris is the only agent out of which to make a perfect dressing. In all injuries about the spine, when it is necessary to secure fixation no agent acts so perfectly as plaster-of-Paris. In general surgical practice it would be very difficult, at least, if not impossible, to find a substitute for it; while silicate of soda is very convenient at times, and makes a fair substitute in certain cases, yet we could dispense with it altogether without much inconvenience.

Some surgeons have advocated the use of silicate of soda for the reason that it is always pure and clean and aseptic. I have never had any trouble in securing plaster-of-Paris which was not strictly pure and clean. I always use dental plaster and prepare it myself when I am ready to use it. I have never had any trouble from either in this respect. I think that there is less trouble in removing a cast or bandage of silicate of soda than plaster-of-Paris, and you do not litter up the surroundings as you must do with the removal of a plaster-of-Paris cast. But this is of little consequence, when compared with its efficiency.

There is what is known as the Bavarian splint—a hinge splint—used for fractures of the leg near the ankle, or including the ankle and foot which is easily and conveniently made of plaster-of-Paris but very difficult to make of silicate of soda.

For bandaging the head in cases of injuries when it is necessary to secure fixation as well as cleanliness, I prefer the starch bandage to either the plaster or the silicate. Hence I argue that by experience in the general practice of surgery, we learn to use a variety of ways and means to adjust and keep in apposition the multiplied varieties of fractures which we are called upon to treat. In some cases we use splints, in some bandages, in others neither splints or bandages. I like the ingenious surgeon who can and will devise something new, if he can not readily secure the old favorite with which he is familiar. Many times a hastily devised appliance in case of emergency has proved to be a valuable acquisition to our surgical armamentarium.

#### DISCUSSION.

DR. HARNDEN—Dr. Jay has called attention to an important point. I know some men who call themselves prominent surgeons who use silicate of soda in cases of fractures of the larger limbs. I was called in six months ago to assist a confrère in applying a silicate of soda dressing to a fracture of the femur in a child about 10 years of age. The child was subject to convulsions and I protested to the doctor against using silicate of soda, although he said it was all right, and he preferred it to plaster-of-Paris. I assisted him in using it under that protest. The limb was badly deformed, and it was caused, the doctor says, by the convulsions, the limb being drawn out of shape before the silicate of soda had thoroughly hardened. I call attention to that point. The Doctor has brought it out very nicely.

DR. WEBB J. KELLY, of Galion, Ohio—Dr. Harnden's remarks bring to my mind a case I saw two or three years since that involved a considerable amount of money, and the treatment was questionable. A passenger on our Southwestern Limited stepped off of the back end of the train and had one limb badly injured about the knee. His home was in St. Louis, he having a brother there who was a practicing physician. He came under our immediate care. We dressed the limb with plaster-of-Paris, applying the dressing nicely, and then telegraphed for his brother. His brother

arrived the next morning, examined the case, said the dressing was too heavy, and that there was no sense in using such a dressing. He took off the plaster-of-Paris and applied silicate of soda. In one hour thereafter the patient was placed on a cot and taken to St. Louis, and only a short time ago I was told that in about three or four months thereafter the man died. His death involved a point that came up with his insurance, whether he could have died from that injury, or whether it was the injury sustained in connection with moving him with this light dressing on, some seven or eight hundred miles. There were two accident companies represented in the case and they fought it vigorously, so that the heirs never got a cent. This is a point that nobody ever thought of.

DR. PARKER—I will suggest one point in regard to the use of plaster-of-Paris. I recognize the usefulness of such a dressing, as we all do. I also have found in my own practice that it is not well to apply it immediately in some of the severe injuries we are called upon to treat. I have waited a few days, applying some temporary dressing until the swelling has reached its height, then applying the plaster-of-Paris dressing. In children there is no question of plaster-of-Paris setting quicker, and in fractures that are still movable, it is a more rapidly setting material than silicate of soda. I have been in the habit for a long time, in order to make my plaster bandage lighter, of using pasteboard. You know how easily this material can be torn. It is not necessary for you to cut it with the scissors, but you can tear it easily and use it in connection with your plaster. There is one point I would suggest for your consideration. Possibly you have observed the same thing. It is a frequent custom with surgeons to take a case that has been in splints, where there is a good-sized callus, and put on a plaster bandage, and on the fourteenth day or so allow the patient to get up. I have noticed in those cases that when the bandage is opened at the end of fourteen days or more that the callus has almost entirely disappeared and union had not taken place, although when it was put in the cast there was every evidence that union was taking place. The callus was ample and the indications were that union was taking place. I have a theory to suggest for that which is this: I think the pressure of the bandage on all sides upon the nutrient vessels interrupts or disturbs the normal nutritive action and arrests the callus-forming process. I have seen this a number of times and I have no better explanation for it. I have seen the callus disappear very largely and union delayed. If the limb in these cases is put back into a Volkmann's splint or some apparatus of that kind, in another ten days the leg is solid. On the other hand, I have seen union delayed where Buck's extension has been used on the femur, whereas if the patient's limb is put in a plaster-of-Paris dressing union takes place. It is in those cases where there is a good-sized callus and the bandage has been applied snugly, all swelling having disappeared, that the plaster-of-Paris dressing delays union. I call attention to one method of using plaster-of-Paris in spinal injuries because we all have them to treat more or less. I have found the hammock method of applying a plaster jacket to be very advantageous. I make it a rule invariably in spinal injuries to apply a light jacket, because it is impossible to think of suspending patients in a Sayre apparatus. In the hospital with which I am connected they have rigged up an apparatus for this purpose.

DR. H. J. MAYNARD, of Cheyenne, Wyo., stated that in all fractures below the knee—even in compound fractures, unless there be much destruction or laceration of soft parts, plaster-of-Paris has been for years his strong hold. In Wyoming he has encountered a great many cases of fracture of the leg among cowboys from falling off horses, and these fractures were almost always below the knee. The first hint he got with regard to the use of the plaster stirrup in fractures was from Dr. Hodgen, of St. Louis, and he has since used it with excellent results in a great many cases.

DR. LEMEN said if there were any members present who were not familiar with the manner of making and applying the plaster stirrup, he would demonstrate how it was done. (This he did.) In the last twenty-five years he said he had treated over six hundred fractures with the plaster stirrup and invariably he has obtained good results in cases of fractures below the knee. There were three cardinal principles to be observed in regard to the treatment of all kinds of fractures: 1, the diagnosis—the surgeon should be sure that he has a fracture before he applies a dressing; 2, place the fragments in position; and 3, retain them there. If these three principles are observed the results would invariably be good.

(To be continued.)

Anonymous Schools	356	322	221	118	*1057	1067	910		16.1+

1 A number preceding a college title refers to a note of comment bearing the same number in the Notes and Comments column following this Table. \* Including 40 specials.

The foregoing table gives the following aggregates for the 101 reporting Colleges, including 7 not specified by name, but whose totals are given under the title "Anonymous Schools."

First year students . . . . .	6,198
Second year students . . . . .	5,248
Third year students . . . . .	3,998
Fourth year students . . . . .	781
Special and irregulars . . . . .	2,359

Aggregate attendance, 1894 . . . . .	17,784
Aggregate attendance, 1893 . . . . .	15,865
Aggregate average previous years . . . . .	14,559

Percentages of increase:

1893 over average of previous years . . . . .	8.9
1894 over 1893 . . . . .	12.4
1894 over average of previous years . . . . .	22.1

NOTES AND COMMENTS.

<sup>1</sup> Estimated; return made "first day of regular winter term; students not all in. Decrease in numbers since 1891-92 due to adoption of three years' compulsory course."—Med. Dept., Arkansas Industrial University.

<sup>2</sup> "We have just adopted a four-year curriculum. In the first year of the table, seventy-five includes students of the first and second years of the four-year course, i.e., first year thirty-seven, second year thirty-eight; total seventy-five. I may say in addition that these figures include from two to five physicians each year—as well as a number each year who do not 'stick,' but as the same occurs at other colleges I presume these figures will afford basis for comparison."—Cooper Medical College.

<sup>3</sup> "The decrease in our attendance can be directly traced to the unequal competition of a State school removing to Denver and taking any student who applies, at no cost to the student whatever. It also means that our standard has been maintained."—Denver Medical College.

<sup>4</sup> "Four-years' course begins with the session of 1895-96. A large increase occurred in sessions of 1893-94, owing to second and third years being taught in Denver, instead of Boulder, giving good clinical advantages. The increase seems likely to continue."—Med. Dept. University of Colorado.

<sup>5</sup> "You will note that there has uniformly been a larger number of students in the first year than in the second or third. This has been due to the fact that a very considerable number of students fail at the end of the first year, and therefore have to repeat their work. Our entrance requirements are placed at the high school grade in the subjects in which we require examinations, and these requirements are well enforced, yet we have this large percentage of failures of men who can not stand the work of our first year. I do not know whether this is the experience elsewhere, but certainly our matriculation requirements are higher than the average of the country, and the whole thing seems to me to be a strong argument for the necessity of a higher grade of matriculation. I have felt for some time that this increase in the matriculation requirement was more needed in this country than the increase of time of study; that is, that three years with well prepared students would be better for the profession than a larger number of students kept at their professional work for a year longer. This opinion, however, does not seem to be the one which has prevailed. We have delayed starting the four years' course, hoping that there would be a general increase in matriculation requirements first, and while we do not altogether give up the hope of increasing matriculation examinations, we are about to adopt the four years' course in conformity with the other schools of the better class. I wish you might have included in your examination, the question of the proportion of medical students who are college graduates, and whether this is increasing or diminishing."—Med. Dept., Yale University.

<sup>6</sup> "In this list the third and fourth years are given together, as last year was the beginning of the four year system."—National Medical College.

<sup>7</sup> "A large number of students who matriculated last year withdrew and went to schools with a three-year course. The four-year course was made obligatory last year. This probably reduced the number of matriculates this year."—Med. Dept., Georgetown University.

<sup>8</sup> "Four years' course began with the session of 1892-93."—Med. Dept., Howard University.

<sup>9</sup> "The scholastic year has just been changed to a three-year term, and this is the first year of such change."—Atlanta Medical College.

<sup>10</sup> "Small attendance in our second course is attributed to the fact that those who attended with us in 1893-94 can graduate in ——— Medical College at end of this term, while we would require them to attend until end of 1895-96. Those seeking early graduation have thus left us. The large increase in our first-year course is due to the school having adopted a three-year graded course and having by hard work for fifteen years established a very good reputation for giving thorough instruction." Total attendance 1894-95 (82) includes "one fourth year." The college, however, is not a four-year school.—Southern Medical College.

<sup>11</sup> "The reason of decrease is on account of the grade being raised and examination more difficult; also our course being four years instead of three."—College of Physicians and Surgeons of Chicago.

<sup>12</sup> "There is a larger percentage of students who have attended literary colleges than in any former year."—Central College of Physicians and Surgeons, Indianapolis.

<sup>13</sup> "Faculty reorganized in 1890-91, with resulting steady improvement in size of the class."—College of Physicians and Surgeons of Keokuk.

<sup>14</sup> "Our school two years ago adopted a four years' course of study."—Med. Dept., New Orleans University.

<sup>15</sup> "Total 409 includes 'two fifth year, one eighth year and thirty-six' not graded at date of making report."—Baltimore Medical College.

<sup>16</sup> Attendance 1893-94 includes three women; first year, 1894-95 includes eight women; second year 1894-95 includes two women. "Our medical school is now in its second year. A noteworthy fact is that all of the fifty-two persons admitted in the two years are graduates of a reputable college, holding baccalaureate degrees, and several of them have pursued graduate studies in the sciences after completing their college work. In addition to these undergraduates in medicine, a large number of physicians are attending special courses in the Johns Hopkins Hospital given by University professors: 1893-94—65; 1894-95 (to November 21)—44."—Johns Hopkins University.

<sup>17</sup> "The large senior classes in 1891 and 1892 were due to the fact that in 1890 we changed from a three to a four years' course. This change, which was announced some years beforehand, brought us large classes in 1888 and 1889, students realizing that if they entered later than 1889, they would have to spend four years here. The small senior class in 1893 is explained in the same way. It appears from the figures that we have fewer medical students than we had last year. This is not true. The number is about the same as it was this time last year. There are always students coming here in the fall, who are unprepared to enter the medical course and have to do some work in the literary department or in the high school before they can enter. Some of these will enter the medical department at the beginning of the second semester. They will not be able to graduate with those who entered this last October, but it will increase the number of students appearing on our register when it is published next spring."—Dept. of Med. and Surg., University of Michigan.

<sup>18</sup> "This college was reorganized last year, so members for past years would not be of value for statistical purposes."—Minneapolis College of Physicians and Surgeons.

<sup>19</sup> Causes of increased attendance: "Faculty thoroughly reorganized and prominent teachers from numerous Western schools having been selected. Also refusal to admit inferior students—no candidate being accepted unless presenting diploma of college or high school. College has no entrance examinations; they are farces!"—St. Louis College of Physicians and Surgeons.

<sup>20</sup> There has been an increase, due to the fact that the school has offered unusual clinical advantages, which have attracted students, in spite of the business depression. This increase is so marked, as evidenced by the fact that more than one-third more actual attendants are present, so that the capacity of the college is strained to accommodate the students. Matriculation list is twenty-five higher than attendance."—University Medical College of Kansas City.

<sup>21</sup> "There was a marked falling off last session. The chief cause was, I think, that no one could graduate on two terms and such sought other schools. One of these now finds that his two-term diploma will not register him and he proposes to take another course. Another cause was that some of them thought they could more certainly graduate in another school. The hard times was another cause."—Ensworth Medical College and Hospital.

<sup>22</sup> "We had forty-three students in attendance last session; this year thirty-one—decrease the result of the scarcity of money."—Woman's Medical College of St. Louis.

<sup>23</sup> "The present is the ninety-eighth annual course of lectures at this college, and the number of students is the largest in its history. Causes: A hospital has just been

opened in town. Possibly the depression in general business may have some influence."—Dartmouth Medical College.

<sup>24</sup> "There is a decrease in the first year, due to the establishment of the four-years' course."—College of Physicians and Surgeons of Columbia College.

<sup>25</sup> "Not complete; return made November 1."—Albany Medical College.

<sup>26</sup> "The junior class of session of 1891 was the first under the graded system."—University Medical College of New York City.

<sup>27</sup> "Our collegiate year does not close until June, 1895, and we always have a considerable number entering our reading term in March—these will bring our number for 1894-95 up to 280 or more. This is the largest class we have ever had, and is undoubtedly due to the clinical advantages we offer."—Long Island College Hospital.

<sup>28</sup> "1890-91 was the last year of the two-years' system; 1891-92 was the first year of the *obligatory* three-years' system. The unusually large class of 1890-91 was due to the fact that many students intend to take advantage of the two-years' system. In 1891-92 three courses of lectures were made obligatory. Students were required to pay for each course attended and the fees on lectures were raised from \$140 to \$150. *Unclassified* includes those who did not attend the full regular course." In the total 409 for 1894-95 are included 60 "unclassified," and in the total 407 for 1893-94 are included 85.—Bellevue Hospital Medical College.

<sup>29</sup> "Our four-years' course began with the session of 1893-94 and there are consequently no fourth year students as yet." The total third year students (thirty-four) include eight who are in the third year of the four-years' course.—Woman's Medical College of the New York Infirmary.

<sup>30</sup> "With the session of 1896-97 we will require a fourth year. It is now optional."—Med. Dept. Western Reserve University.

<sup>31</sup> "The increase seems to affect all schools, more or less, and is probably due to prospective enforcement of the four-years' course next year."—Starling Medical College.

<sup>32</sup> "Increased facilities for instruction over years gone by have increased our class from thirty-eight the past season to fifty for the present."—Toledo Medical College.

<sup>33</sup> "The increase is due largely to the reputation of the school among college-trained students and school teachers. Our school is conducted on the normal methods of teaching. The students are enthusiastic and spread the good news to their friends seeking a medical education."—Ohio Medical University.

<sup>34</sup> "Increasing good reputation of the school and perhaps because of lack of opportunities for employment on account of times has driven more persons than usual to professional study."—Med. Dept., University of Oregon.

<sup>35</sup> "The total number in attendance this year (session of 1894-95) may be increased by about thirty when students at present under conditions are permitted to matriculate after their conditions are passed."—Med. Dept., University of Pennsylvania.

<sup>36</sup> "Partly due to the fact that we begin our compulsory four years' course next year. Any progressive movement like this increases the popularity of the school as it indicates a determination to take a higher stand among the medical colleges."—Jefferson Medical College.

<sup>37</sup> "The recent reduction in the number of students was probably due to the lengthening of the course of study to four years and the advance in the standard of entrance requirements adopted by the college."—Woman's Medical College of Pennsylvania.

<sup>38</sup> "The great clinical advantages by reason of its proximity to a large general hospital, viz.: The Western Pennsylvania Hospital. This and the fact that we have adopted the three-years' graded course explains the increased attendance."—Med. Dept., Western University of Pennsylvania.

<sup>39</sup> "Our facilities for teaching are being yearly increased and an increasing number of students are in attendance."—Medical College of the State of South Carolina.

<sup>40</sup> "We now have a four-years' course of study."—Meharry Medical College.

<sup>41</sup> "The decrease is owing to the stringency in money matters all over the country."—Tennessee Medical College.

<sup>42</sup> Heretofore conducted as a spring and summer school, not graded. "The school has now withdrawn from the Southern Medical College Association and will teach annual terms of ten months, from first of March to latter part of December, and permit students to apply for graduation after attendance upon two such annual terms and three years of study."—Sewanee Medical College.

<sup>43</sup> "We have no required third year, but some students

distribute their study over three years." Two annual sessions of nine continuous months each are required for graduation. "The increase of students is due to the establishment of the graded course."—University of Virginia.

<sup>44</sup> "We have ten State scholarships, given in consideration of the fact that we receive aid annually from the State. We have no other scholarship feature, as is so often found in other medical institutions, or our number of matriculates would have been greatly increased. We have no dental or pharmacal department connected with our school. It is proper to state that the number of students above for session 1894-95 is incomplete, as we expect a number more to come in soon."—Medical College of Virginia.

<sup>45</sup> "During the last session the qualifications for degree were increased from four six months' sessions and two compulsory summer sessions of three months each, to four sessions of nine months each. The increase in students was unexpectedly large this year which we attribute chiefly to the increased clinical advantages afforded from the opening of the new Royal Victoria Hospital."—Faculty of Medicine, McGill University.

<sup>46</sup> "The increase during the present session is probably due: 1, to the fact that the enlargement of the building last summer, increasing it to double its former size, was well advertised throughout the Province; 2, the work of the college is becoming favorably known; 3, the proportion of young men entering the profession in this section of the country, as shown by increasing attendance, is rapidly (too much so, possibly), on the increase; 4, it has become generally known that it is the intention of the college to lengthen the term. This has had the effect of bringing a few students in earlier than they would otherwise have come."—Manitoba Medical College.

## NECROLOGY.

DUJARDIN-BEAUMETZ, M.D., of Paris, at Nice, France, February 15, aged 61. He was physician to the Hôpital Cochin and a well-known writer on therapeutics. He had many friends among the medical profession of America, and was a member of the Ninth International Medical Congress at Washington, 1887.

CHAS. W. BREYFOOLE, M.D., who was for several years a leading physician of Louisville, died at his late residence, San Jose, Cal., on the 28th ult. He was 54 years old, was born in Columbus, Ohio, lived in Louisville, and in 1872 moved to San Jose on account of ill health.

SIR WILLIAM SCOVELL SAVORY, F.R.S., Surgeon Extraordinary to the Queen, and late President of the Royal College of Surgeons died in London, March 4, aged 69 years.

JOHN CAMPBELL THOMPSON, for many years a practitioner at South River, N. J., died February 14, in his sixty-seventh year. He was a graduate in medicine at the College of Physicians and Surgeons in the class of 1856.

MILTON N. TAYLOR, M.D., of Baltimore, died February 25, aged 68 years. He was a native of that city and a graduate in 1848 at the Washington University School of Medicine, since merged with the College of Physicians of Baltimore. He was connected at odd times, from the year of his graduation, with the administration of health affairs. He was the City Physician in 1853 and 1854 and a Commissioner of Health from 1867 to 1871.

T. S. HOLLINSHEAD, M.D., of Harrisburg, Pa., February 25.—J. F. Parks, M.D., Bourbon, Ind., February 28.—A. J. Bell, M.D., Atlanta, Ga., February 23.—I. de Zouche, M.D., age 72, Gloversville, N. Y., February 22.—Francis Obetz, M.D., Grove City, Ohio, February 20.—W. D. McWhorter, M.D., Washington, D. C., February 20.—A. J. Robb, M.D., Owosso, Mich., February 26.—J. H. Sherrod, M.D., Paoli, Ind., age 52 years, February 26.—Grace Danforth, M.D., Granger, Texas, February 21.—I. M. Ward, M.D., Lyons Farms, N. Y., age 89 years, February 25.—Ben Smith, M.D., Mount Upton, N. Y., February 23.—L. S. Henthorn, M.D., Indianapolis, Ind., February 25.—W. H. Seobey, M.D., Hamilton, Ohio, February 27.

Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE . . . . . \$5.00

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

NO. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MARCH 9, 1895.

SOURCES OF ARROW POISON.

Commenting on LEWIN's work on arrow poisons (*Die Pfeilgifte*) LAGNEAU observes that many of the European peoples in ancient times employed poisoned arrows, but most authors who mention the fact neglect to state the mode of preparing the poisons. Some of these appear to have been composed of vegetable extracts of great toxic power, and others of venoms or putrified animal matters, undoubtedly containing ptomaines.

The Gauls, according to PLINY, dipped their arrows for the chase in the juice of hellebore: "*Galli sagittas in venatu elleboro tingunt.*" (Hist. Nat., lib. xxv.) He also speaks of an herb called *limeum* by the Gauls, from which they made a preparation which they called "poison of the deer:" "*Limeum herba appellatur a Gallis, qui sagittas in venatu tingunt medicamento, quod venenum cervarium vocant.*" (Hist. Nat., lib. xxvi.) STRABO and ARISTOTLE also mention poisoned arrows for hunting used by the Celts. The Scythians, according to OVID, then in exile on the shores of the Black Sea, coated their arrows with the gall and blood of the viper—more probably its venom. Different Greek authors also speak of the viper as being used to poison arrows, but ARISTOTLE notes that the Scythians add human blood—*ἀνθρώπων αἷμα*—to the viper venom. "When this blood is equally putrified," says ARISTOTLE, "the serous liquid which rests on top is mixed with the putrid viper and thus they make a mortal poison." (*De Mirab. Auscult.*, cap. cxli.)

LEWIN states that among the Somali of North-east Africa a blackish material called *waba* is used; this is extracted from plants of the *Apocynaceae* and is identical with amorphous ouabain. Among

the Waitata of Central Africa the poison more nearly resembles crystallized ouabain. Other Central African tribes, the Waschamba, Wanika, etc., like the Somali, use amorphous ouabain. The peoples of South Africa possess modern arms, using poisoned weapons only exceptionally, so that in the near future these tribes will have lost the art of weapon poison. In the rest of Africa the poison used is sometimes ouabain, sometimes strophanthin, sometimes a mixture of the two.

In Asia, aconite seems to be preferred to other poisonous substances. During the French war with Tonquin in 1878, REGNAULT showed that the natives used a cardiac poison extracted from the *Antiaris toxicaria*. Many soldiers were wounded with weapons thus poisoned—in one skirmish a lieutenant and two privates, but only one of these had dangerous symptoms.

TREATMENT OF PENETRATING WOUNDS OF  
THE CHEST.

In the *Revue de Chirurgie*, for Jan. 10, 1895, there appears an interesting article on the conduct of the surgeon, in the case of penetrating wounds of the chest by side arms, by HUGUET and PÉRAIRE, who quote numerous observations by TERRIER and LUCAS-CHAMPIONNIÈRE, and by themselves.

The code duello is so much in vogue in France that even in the "piping times of peace," there is abundant opportunity for the study of this class of wounds.

The authors make very clear by their observations that early removal of such patient from the field is extremely dangerous, unless every precaution be taken to immobilize the chest wall as far as possible. The following is a summary of their conclusions:

1. There is absolute necessity of treating the wounded, at the place; the gravity of the concussion communicated by transportation, whether the journey is long or short, gives even stronger reason, as treatment may be performed in the carriage. If it is necessary to transport the wounded to a distance the inevitable jolting of the vehicle will produce hemoptysis or accentuate it, and this may induce the death of the patient.

2. The state of syncope favoring hemostasis may be respected in a certain degree, but it may become necessary to make moderate subcutaneous injections of ether, to the end that the depression may not become too considerable. It is in such cases that above all we may have recourse to caffeine and to hypodermatic injections of artificial serum.

3. The treatment of penetrating wounds of the chest by ordinary means (cold applications and iced drinks, injections of ergotin, compression, antiseptics, ligature of vessels, suturing of the wound) appears to us insufficient in many cases, unless immediately subjected to as absolute immobility as possible. Thanks to this absolute rest which results from forced immobilization of the entire pulmonary apparatus, there is obtained a condition from the outset which alone may insure success.

4. It goes without saying that this immobilization does not exclude the ordinary means mentioned.

5. In case of hemothorax consecutive to a lesion of a great vessel, there is no urgent need, the phrase "*expectation armée*" (armed neutrality) never finds a better application than in such circumstances. It is necessary to be guided by the symptoms and above all by the complications, to come to a determination. It is not necessary to resolve upon thoracentesis until the effusion becomes too considerable, and the dyspnea excites serious fears for the case.

6. The indication is in all cases of penetrating wounds of the chest to banish the permanent dressing; to make an elaborate dressing of the wound, being restricted to the necessities of the case, and always avoid jolting or concussions.

The treatment recommended must commend itself to all military surgeons, notwithstanding this subject has furnished food for discussions from time immemorial.

THE forty-sixth annual session of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9, and 10, commencing on Tuesday, at 10 A.M.

#### SANITARY EXPENDITURE PAYS.

At the recent Indian Medical Congress—the first, by the way, in the annals of Indian medicine—SURGEON-LT-COL. W. G. KING, D. P. H., delivered the Presidential address on Public Health, in which he pointed out that during the last six and a half years 201,394 deaths were registered from smallpox in the Madras Presidency. Taking into account the probable number of survivals from these attacks at 64.3 per cent., he calculated that—without considering the capitalized value of lives—there must have resulted, during sickness and upon funeral ceremonies, an unproductive expenditure of 51 lakhs of rupees—if it be presumed that the persons attacked occupied no higher position than the coolie gaining Rs. 5 per month. Translated from East to West, in terms of currency, this means that a sum equivalent, in round numbers, to about \$48,000,000 was wasted in six and a half years through a preventable disease—to say nothing of the suffering, the disabilities of the survivors and the loss of human life.

On the other hand, one day last week the municipal authorities of Chicago dedicated, with appropriate ceremonies, what is known as the "four-mile crib." This is a structure covering the intake of an eight foot tunnel running out into Lake Michigan a distance of four miles from the city, with a daily capacity of 140,000,000 gallons, taken from the lake at a point beyond the observed limit of shore pollution. As a matter of fact the tunnel has been in operation since December, 1892—a period long enough to furnish some interesting data concerning its effect on the death rate from typhoid fever and the diarrheal diseases. The Health Commissioner, DR. REYNOLDS,

showed that during the three years from Jan. 1, 1890, to Dec. 31, 1892—about which latter date water was first let into the tunnel—Chicago had an average annual death rate from typhoid fever of eleven and one-half in every 10,000 of population. In 1893—that is, during the first year's duty of the tunnel—this rate was reduced to four and one-fifth in 10,000, and last year it was still further reduced to three and one-tenth in 10,000. Up to the close of 1892, Chicago had, year after year, the greatest typhoid death rate of the seventeen principal cities of the Union—all those having populations of 200,000 or over. In 1894 the city had moved up from the lowest to the tenth place in the scale of healthfulness in this respect, with a rate of 3.1 in 10,000, being outranked by New Orleans (3.0), Milwaukee (2.5), Boston (2.4), Cleveland (2.2), New York (1.6), and Brooklyn (1.5), and outranking Philadelphia (3.3), St. Louis (3.5), Minneapolis (4.6), Baltimore (4.8), Louisville (5.0), Cincinnati (5.2), Pittsburg (5.6), Buffalo (5.7) and Washington (8.1).

It was further pointed out that while the greater or lesser prevalence of typhoid fever is generally accepted as an indication of the character of the water supply, it is by no means the only disease whose prevalence is increased by impure water. The diarrheal diseases are similarly affected, and these cause in the aggregate a larger number of deaths than typhoid. In the four years, 1890–93 inclusive, there were 7,803 deaths in Chicago from the diarrheal diseases—a yearly average of 1,951. In 1894 there were only 809 deaths from these causes—a reduction of over 58 per cent. If the same death rate had obtained from typhoid fever and the diarrheal diseases in 1894 that obtained in 1890, '91, '92 and '93, there would have been 2,153 more deaths from these causes than there really were. Accepting the capitalized value of a human life at \$5,000—an estimate which is indorsed by the Legislatures of many States in fixing the penalty upon railroads for killing people outright—this would give an aggregate of \$10,765,000 saved as against the cost of the tunnel construction and pumping plant (\$3,083,000), leaving a balance of \$7,682,000 to the credit of an improved water supply over and above its cost.

In this computation, however, no account is taken of a still larger factor of cost. Each death from typhoid represents, probably, twenty cases—nineteen of whom recover and are never mentioned in statistics; each death from the diarrheal diseases similarly represents probably forty cases—say an average of thirty cases to every reported death. If, then, an improved water supply prevented 2,153 deaths from these diseases, it also prevented nearly 65,000 cases of these diseases, and has also saved their aggregate cost of medicines, medical attendance and nursing, of time taken from business or productive work, and

of expenses of many other kinds incident to the sick room.

Sanitary expenditure pays, whether in vaccinating against the smallpox or in providing a pure water supply. That is to say, it pays the community, whatever may be its effect on the income of the practitioner.

#### EXACT ENGLISH AND PURE WATER.

Although REPRESENTATIVE BARTHOLDT's efforts to secure the passage of a bill—to appoint a commission for the investigation of the pollution of water supplies where such pollution affects or threatens to affect the sanitary condition of the people of more than one State—failed at the session of Congress just closed, it is to be hoped that he will renew the attempt at the earliest opportunity and push it to a successful conclusion. The subject matter is one in which every sanitarian is interested and the moot questions involved should be promptly and authoritatively settled. Meanwhile, the agitation has not been without result, since the text of the measure has furnished occasion for an excursus upon the exact use of language which the JOURNAL thinks may be profitably reproduced.

Commenting editorially upon the bill, an esteemed contemporary had this to say: "One of the sections provides that 'at the next session of Congress the commission shall submit such suggestions as may seem desirable for the purpose of remedying any insanitary conditions that may have been developed by its work.' Surely this is not what the framer of the bill meant, for he can hardly intend that the commission shall go into the business of developing insanitary conditions; he has simply lapsed into 'sloppy English.'" To which the framer of the bill, DR. CHARLES SMART, Surgeon, U. S. A., responds that this is precisely what he meant and intended. "The transitive verb *develop* means to take a thing out of the wrappings or obscurities in which it is enveloped. The thing referred to is in existence, but it is not apparent until its existence is developed by some agency. It may be intangible—an idea, for instance; but the existence of the idea may be developed by the use of words spoken or written. It may be invisible, as is the photographic picture, which can be seen only after it has been developed by certain chemical solutions; or it may be a very material and substantial thing, as a hostile army in line of battle, the position of which may be developed by reconnoitering parties. The first two illustrations are analogues and the last is the homologue, from the literary standpoint of 'the insanitary conditions which may be developed [*Synonyms*: uncovered; unfolded; laid open; disclosed; exhibited; unraveled; disentangled; detected.—*Webster*.] by the labors of a commission of competent investigators.' Some persons, through ignorance or carelessness, use the word in the sense of to produce or to cause to come into existence,

Against these the charge of lapsing into slovenly English may be preferred with justice, but certainly not against those who give the word its true value."

All of which goes to show that Analyst SMART is no less doughty a champion of English undefiled than of water unpolluted.

#### THE TRIUMPH OF M. PÉAN.

The session of the Académie de Médecine of Paris held January 15, was made remarkable by the presentation of a patient by M. PÉAN.

This patient had had a carcinoma of the larynx and to relieve it, it was necessary for M. PÉAN to make entire extirpation of the larynx, the superior portion of the esophagus and the inferior portion of the pharynx. Not only did the patient support the mutilation, but by means of a prothetic apparatus constructed by M. MICHAËLS, under the direction of M. PÉAN, the organs were replaced so that the patient could breathe, eat and drink. Not only that, but the apparatus allowed the patient to make articulate sounds, so that speech could be understood. It is two years since the patient was operated upon, and the crowning glory of the operation has been the phenomenal, nay, the brilliant success of the artificial larynx. In former times the saving of the life of a patient so afflicted would in itself have been a triumph of surgery, but to replace lost parts with apparatus of such delicacy and usefulness seems to represent an art almost superhuman.

#### HENRI DE MONDEVILLE.

In a scholarly article by DR. ADRIAN SCOTT in the *Atlantic Medical Weekly*, March 2, 1895, we note the following:

"The oldest French writer upon surgery is HENRI DE MONDEVILLE, at first teacher in Montpellier, then body surgeon to PHILIP THE FAIR. He was at the same time one of the earliest French writers upon anatomy, the instructor of CHAULIAC. His 'Chirurgie' has never yet been printed."

This is an error, for the *Chirurgie* of MASTER HENRI DE MONDEVILLE was published last year. In our issue of April 28, 1894, we published a leading article on the work, and complimented the editor, M. NICAISE, on his great public service in rescuing DE MONDEVILLE's work from the obscurity in which it had so long remained.

If DR. SCOTT had read this JOURNAL carefully he would not have fallen into the serious error which we have noted.

#### THE DATE OF THE ASSOCIATION MEETING.

By an unfortunate error in the publication of SECRETARY ATKINSON's circular, the date was given as June. The actual date is May 7, 8, 9 and 10.

There need be no confusion if one will always remember that for many years the rule has been that when the ASSOCIATION meets south of MASON and DIXON's line, the meeting is invariably held in May; when north of that line in June.

## CORRESPONDENCE.

## A Warning against Castration for Prostatic Enlargement.

CHICAGO, Feb. 25, 1895.

To the Editor:—Permit me to utter through your columns a warning against promiscuous castration for prostatic enlargement. The operation is so easy and the relief afforded sometimes so great, that some seem to have forgotten the existence of other means to the same end. In several of the nineteen cases already reported, it would seem that complete relief should have been afforded by a simple incision, or simpler puncture, or perhaps even by a catheter in a practiced hand.

The interesting analogy between uterine myoma on the one hand, and one element in prostatic enlargement on the other, has obscured to some of us the other element in this enlargement, the *inflammatory*; which while playing no rôle in uterine myoma, is the important clinical factor in all severe cases of prostatic hypertrophy.

I hope to discuss this element at length in another place, and to show that a process which I call "milking the prostate" is an efficient measure for the relief of prostatic enlargement; at present, I shall merely mention the admitted facts that suppuration in the prostatic glands (prostatico-cystitis) occasions the patient acute distress, and that inflammation in the parenchyma results in the edema and connective tissue hypertrophy which constitute much of the enlargement. That castration may cause atrophy of glands, subsidence of edema and hence relief of distress is admitted; but that it will not reduce the hypertrophied connective tissue is *a priori* probable and seems proved by at least two of the cases already reported.

If the argument were ended here, the relative merits of castration and incision might be debatable; but there is another feature which, in my opinion, makes castration as the operation for the relief of prostatic hypertrophy dangerous to the surgeon namely, the impossibility of knowing that the cystitis is due to the apparent hypertrophy. It is well known, for example, that prostatitis very often have vesical calculi which may indeed be the chief cause of suffering; and that in such bladders calculi may easily escape detection by the sound because concealed by the projecting prostate or in diverticula. I emphasize this fact because there have come to me within six months, two elderly patients suffering from prolonged and severe cystitis ascribed to the undoubtedly swollen prostates, each of whom had been urged by his physician to submit to castration. Careful search with the sound revealed a calculus in one, but failed to detect in the other a small stone which was found by supra-pubic incision lying below the swollen prostate. Prolonged vesical drainage was followed by great reduction of the prostatic enlargement (evidently inflammatory) and a symptomatic cure. Imagine the status—professional and legal—of the surgeon who might have castrated either of these men, when the calculus was subsequently discovered.

A mistaken diagnosis of simple prostatic enlargement—because this is a common cause of severe cystitis—is sometimes made when the real trouble is a less familiar condition, such as cancer, papilloma, tuberculosis, or concealed stone. It seems to me therefore that whenever a case of real or supposed prostatic enlargement demands operative relief, this should always be an incision into the bladder; castration, if it have any place at all, must compete with prostatectomy and not with simple incision which, in the interest of surgeon as well as patient, should precede it. The claim that double castration is safer than drainage is

not, in my experience, warranted, if drainage be made by either perineal urethrotomy or supra-pubic incision in *deux temps*; the danger in cases that really demand operative interference is the anesthetic, not the knife.

WM. T. BELFIELD, M.D.

## Treatment of Gonorrheal Conjunctivitis.

MINNEAPOLIS, MINN., Feb. 23, 1895.

To the Editor:—Two recent cases of conjunctivitis have interested me and are perhaps worth publishing. Jan. 7, 1895, Dr. B. asked me to visit and take charge of a case of purulent conjunctivitis, to which he had been called during the night. A young bride of two weeks, a healthy blonde, had suffered for four days from a profuse muco-purulent discharge of left eye, for which she had used some domestic eye wash and warm fomentations. Dr. B. had been called on account of severe pain which was relieved by morphia and hot water. I found intense congestion of entire conjunctiva, pupil strongly contracted, and a muco-purulent discharge which under the microscope showed only a few pus cells and streptococci, some of the latter in pairs. The eye was thoroughly washed out with boracic solution, mopped with 2 per cent. silver and again flushed with boracic solution. A single drop of 4 grains solution atropia was instilled, and the eye was flushed every fifteen minutes during the day. In eight hours it was much better. The two following days 1 per cent. silver was applied. There was almost no discharge. The fourth day the eye was white, slightly sticky in the morning, but free from irritation, and in a few days more entirely well. There was nothing beyond a slight occasional leucorrhea which could be suspected of being a causative factor.

Jan. 12, 1895, Dr. X., a professional friend, came to my office with what appeared a purulent conjunctivitis of both eyes. His eyes were well in the morning, but at 3 P.M., I found a profuse purulent discharge, with intense congestion of conjunctivæ. The eyes were thoroughly washed out with boracic solution, mopped with 2 per cent. silver, again flushed, and this repeated about three hours later. Iced cloths were kept constantly applied until the following morning when the discharge had nearly ceased. The 2 per cent. silver was again applied, and the boracic solution at frequent intervals during the day. On the second morning the eyes were free from discharge and practically well, there being only a few subconjunctival ecchymoses and a yellowish discoloration, with some feeling of stiffness. The microscope showed as characteristic evidence of the gonorrheal nature of the pus as I have ever seen in unquestioned cases.

Dr. A. F. Irwin, Professor of Pathology at the College of Physicians and Surgeons, to whom I submitted the microscopic slide, concurred in my diagnosis. In neither of these cases could the nasal condition have played any special causative part. In the one there was a mild intumescent rhinitis; in the other the atrophic stage of hypertrophic rhinitis. In the latter case, a profuse nasal discharge began and ended with the conjunctival discharge, being evidently secondary.

The first case was probably a streptococcus infection. The second, I am confident, was of gonorrheal origin. My treatment of any acute conjunctivitis is usually introduced by an application of 2 per cent. silver. It is by common consent the proper thing if the case be purulent, and in my opinion the earlier the better. If the case be catarrhal the indication may be less imperative, but it is equally clear.

Yours respectfully,

EDWARD J. BROWN, M.D.

THE forty-sixth annual session of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

**An Inquiry.**

COLUMBUS, OHIO, Feb. 26, 1895.

To the Editor:—I desire to inquire of those among your readers, who have had experience in neural infixation, to give me the following information, for which I will be pleased to give them due credit.

Date and number of cases operated; cause for operation; method of operating, naming the nerve infixed as well as the nerve in which the implantation was made, also the point at which such infixation was made.

My object is to gather reliable statistics in this class of surgery with a view of obtaining more light on this important subject.

Very respectfully yours,

R. HARVEY REED, M.D.

150 E. Broad Street.

[Exchanges please copy.]

**Florida Health Notes.**

PHILADELPHIA, Feb. 24, 1895.

To the Editor:—I noticed in a late issue of the JOURNAL, that the *Florida Health Notes* will publish a series of papers on "Cremation," beginning with January, 1895. I have been trying to find out the address of the said periodical but did not succeed; hence I write to you to kindly give me same on a postal, as you certainly have copies from which the extracts are taken. Many thanks for your kindness.

Respectfully,

REV. E. H. GERHART.

ANSWER:—Address, Dr. J. Y. Porter, Secretary State Board of Health, Jacksonville, Florida.

**Expelled.**

CLEVELAND, OHIO, Feb. 24, 1895.

To the Editor:—Please publish in our JOURNAL, the following resolution as adopted by the medical staff of the German Hospital of this city, viz:

"Resolved, That Dr. F. D. Brandenburg be hereby expelled from this staff for unprofessional conduct, *i. e.*, the giving of a fulsome certificate to the proprietor of a certain mineral water under the name of this staff, without their knowledge or approval, and which certificate we hereby repudiate."

Yours respectfully,

F. W. WALZ, Secretary.

**ASSOCIATION NEWS.****The Baltimore Meeting.**

At a meeting of the Committee of Arrangements held February 26, the Committee of Transportation reported that the various railroads of the country had granted the customary reduction of rates to one fare and one-third on the certificate plan to the delegates attending the meeting, and their families. The Secretary of the Association will publish detailed instructions for obtaining this reduction, through the columns of the JOURNAL.

Hotel rates to delegates will be given in the next issue of the JOURNAL. The Hotel Stafford will be the headquarters of the Association.

Among the entertainments determined upon will be an evening reception by the Trustees of the Johns Hopkins Hospital. A general entertainment will also be given by the profession of the city, but the details of this are not yet completed.

Excursions at greatly reduced rates will be arranged to the Gettysburg battlefield, to Washington and to Annapolis. Further details of these excursions will be given in future issues of the JOURNAL.

An auxiliary committee of ladies will have in charge the

entertainment of ladies accompanying the delegates during the hours when the latter are occupied at the meetings.

The Committee urges Section officers to arrange for the Section dinners on the evening of the first day (Tuesday) in order not to conflict with the arrangements for the general entertainments on Wednesday and Thursday evenings.

The Committee feels that the primary object of the meeting of the Association is the transaction of scientific work, and that diversion and entertainment must be held subordinate to this. Hence no encouragement will be given to any suggestions looking to abridge the time to be devoted to scientific work and the legitimate business of the Association. The Committee hopes, however, to make the visit of the members, the delegates, and their families, agreeable as well as profitable. It is the earnest wish of the profession of Baltimore that no one coming to the meeting will leave our city with the feeling that his time has been wasted or unpleasantly spent.

GEORGE H. ROHÉ,

Secretary Committee of Arrangements.

**American Medical Association Annual Announcement.**

{ OFFICE OF THE PERMANENT SECRETARY,  
1400 Pine Street, PHILADELPHIA.

The forty-sixth annual session will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday, and Friday, May 7, 8, 9, and 10, commencing on Tuesday, at 10 A.M. Railroad rates one fare and one-third for round trip tickets.

"The delegates shall receive their appointment from permanently organized State medical societies, and such county and district medical societies as are recognized by representation in their respective State societies, and from the medical department of the Army and Navy, and the Marine-Hospital Service of the United States.

"Each State, county, and district medical society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number: *Provided*, however, that the number of delegates for any particular State, Territory, county, city, or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association."

*Members by Application.*—Members by application shall consist of such members of the State, county, and district medical societies entitled to representation in this Association as shall make application in writing to the Treasurer, and accompany said application with a certificate of good standing, signed by the president and secretary of the society of which they are members, and the amount of the annual subscription fee, \$5. They shall have their names upon the roll, and have all the rights and privileges accorded to permanent members, and shall retain their membership upon the same terms.

The following resolution was adopted at the Session of 1888:

*That in future, each delegate or permanent member shall, when he registers, also record the name of the Section, if any, that he will attend, and in which he will cast his vote for Section officers.*

Secretaries of medical societies, as above designated, are earnestly requested to forward, at once, lists of their delegates.

**AMENDMENTS TO THE CONSTITUTION AND BY-LAWS.**

[Offered in 1892, and laid over from 1893 and 1894.]

Offered by Dr. C. A. L. REED—Amend Article II, Section 1, of the Regulations, by inserting after the words "United States," "the Dominion of Canada, Labrador, and Newfoundland," and that such other changes be made in the phraseology of the Regulations and By-Laws as to make the same conform to this contemplated enlarged jurisdiction of the Association."

By Dr. I. N. QUIMBY—"That Thursday morning's general session be omitted, and the time be devoted to sectional work."

By Drs. JOHN MORRIS and J. G. KIERNAN.—Amend Section 7 of the Constitution, entitled, "the General Business Committee," as follows: "It shall be the future duty of the General Business Committee to make and present the nominations for the officers of the Association and its standing

committees, and recommend the time and place for the meeting of the Association.

"The General Business Committee of the Association shall perform all duties hitherto performed by the Committee on Nominations, which is hereby abolished. All sections of the Constitution and By-Laws, or parts thereof, inconsistent with the amendment, are hereby repealed."

By Dr. F. F. Dow—Amendment to the Constitution, to be known as Article VIII, entitled: "The Code of Ethics:" "The relations of the physician to the patient, to the public, and to the profession require that he shall be of good moral character, and in his personal and professional conduct without reproach; that he shall avoid pretense and notoriety; that he shall properly qualify himself for professional duty by broad and liberal studies in letters, sciences and arts; that he shall employ reasonable and reputable methods of practice; that he shall respect the laws of the State; that he shall encourage efficient means for the enlightenment of public opinion regarding the responsibilities of medical men and the relation of the citizen to public health, for the cultivation of medical education, for the promotion of the interests, usefulness, and honor of the profession, for the emulation, concerted action, and friendly intercourse among those engaged in it.

"Substituting the Roman numerals IX for VIII.

"All Articles, By-Laws, and Codes inconsistent with this amendment are hereby repealed."

By Dr. J. H. RAUCH—"That on and after July 1, 1897, no one will be admitted to membership in the AMERICAN MEDICAL ASSOCIATION who has not studied medicine for four years, and attended four annual courses of lectures of at least six months' duration."

By Dr. F. F. Dow—Amend By-Law No. XI, relating to the Judicial Council. The second clause of paragraph 3 shall be amended to read as follows: "The decisions of said Council on all matters referred to it by the Association shall be reported at the earliest practicable moment, and shall be final unless revised by the Association."

By Dr. A. B. HOSMER—"WHEREAS, The constantly increasing number of papers on general surgical subjects presented each year at the Surgical Section of this Association, the reading and even restricted discussion of which prohibit the introduction of any considerable number of papers on strictly orthopedic subjects, which might not prove of universal interest to the general surgeon; and

WHEREAS, There are already a sufficient and rapidly increasing number of members of the Surgical Section of this Association especially interested in this branch of surgery to warrant it; therefore be it

"Resolved, To amend Article II of the By-Laws by the addition, under the heading Sections, and after 12, Physiology and Dietetics, the following; 13, Orthopedic Surgery.

By Dr. J. T. PRIESTLEY—"The entire report on Constitution, etc., as offered in the report of Dr. Holton at San Francisco."

#### ADDRESSES.

On General Medicine, by Dr. William E. Quine, Chicago, Ill.; on General Surgery, by Dr. C. A. Wheaton, St. Paul, Minn.; on State Medicine, by Dr. H. D. Holton, Brattleboro, Vt. Committee of Arrangements, Dr. J. J. Chisolm, Chairman, Hotel Stafford, Baltimore, Md.

All members of the Association, and members of the medical profession generally, are urged to attend the Baltimore meeting.

WILLIAM B. ATKINSON, Permanent Secretary.

## PUBLIC HEALTH.

**Tenement-Houses Must Have Adequate Water Supply.**—The New York City Board of Health has recently won a victory in the Court of Appeals over the rich and powerful Trinity Church corporation. The fight has been waged for years with varying success, but it seems that the court of last resort has given the right of way to the Health officers. The following is a paragraph from a telegram dated February 26:

"The church corporation neglected to furnish water on each of the floors of the buildings 77 and 84 Charlton Street and after the Health Department had ordered them to put the water in neglected to do so. The Department fined them \$200 at \$10 a day for every day of neglect after the order was issued. The church trustees contended that the houses

were not tenements, but were built for residences, and although used as tenements now, did not come under the provisions of the act. The case was decided in favor of the city, and judgment of conviction, entailing a fine of \$200 issued. The church corporation asked for a new trial on questions of law and the General Term granted it. The Court of Appeals reverses the decision and denies the new trial."

**Neglect of Vaccination in Italy.**—During the recent smallpox incidence, it was noted that an undue proportion of cases occurred among the Italian contingent of the population. The experience of Dr. James Leishman, surgeon of the steamer *Scandia* of the Anchor Line, throws some light on the cause. He says: "In 1894 I examined over eight hundred Italian emigrants for vaccination according to American law. I regret I did not retain exact figures of results, but many men even of military age had somehow escaped, and more women, while fully half of the children had no marks. On my last voyage, out of 100 children I had to vaccinate over 60. The figures would be more unfavorable if I could subtract those vaccinated just previous to the voyage and those who preferred doing it at home. I was more than surprised to find it is supposed to be universal. These were mainly peasants from the southern half of Italy. While I am writing, I may say that Scandinavians are very carelessly vaccinated, many who have certificates showing no marks; Scotch are rather better, German and Irish are far superior and practically perfect. The Italian lymph is excellent. Other ship surgeons I have no doubt could corroborate me."

**Health of Paris.**—The last official census of the French capital was that of 1891, which fixed the population at 2,424,705, the figures still quoted in the issues of the *Bulletin Hebdomadaire de Statistique Municipale* for 1894. Based on this population, the mortality last year was lower than the average mortality of the previous ten years, being at the rate of 20.20 per 1000 of population. On the same census figures, the death rate for 1891 was 21.55; for 1892 it was 22.49, and for 1893 it was 21.83 per 1000. Since there was an increased birth rate in 1894, this lowered death rate can not be due to loss of population, and the actual number of deaths shows that Paris was unusually healthful in 1894. Last year 48,992 deaths were registered; in 1893, 52,955; in 1892, 54,536; in 1891, 52,262; in 1890, 54,566; in 1889, 54,083. Thus in 1894 the mortality is 4,725 lower than the average. With the exception of short epidemics of typhoid fever and of smallpox, these forms of disease were rare during 1894—during the last six months especially so. The deaths from typhoid fever in 1894 were 695; in 1893, 570; in 1892, 692; from smallpox, 173 deaths in 1894, 260 in 1893. Measles caused most deaths during May; afterward the cases were quite exceptional in 1894; the deaths were 988; in the previous years they were 677 and 909. Scarlet fever 149, the previous years 177 and 158. Whooping-cough 248 instead of 508 and 334. Diphtheria 1,009, instead of 1,266 and 1,403. Deaths from lung diseases were considerably less, and notably contributed to the lowering of the death rate.

**Transportation of Contagious Disease Corpses.**—A case was recently tried before Judge Abner Smith in the Circuit Court of Cook County, Illinois, in which suit was brought against the Chicago and Northwestern Railway Company to recover damages for refusal to carry the dead body of plaintiff's child, the child having died of diphtheria. At the time the corpse was offered, Dec. 26, 1891, the rules of the State Board of Health of Illinois permitted the transportation of corpses of persons dead of diphtheria under certain regulations, placing them in the second class mentioned in the rules. About a year previous to that time the State Board of Health of Iowa and those of several other Western States

changed diphtheria and placed it in the first or prohibited class, so as to forbid absolutely the transportation in public conveyances of bodies of persons dead of diphtheria. When that change was made, the company, as it had lines in many of the States, changed its rules to correspond with the change made by those Boards of Health, and, as a result, at the time the body of the plaintiff's child was offered for transportation the rule of the company forbade its transportation, although such transportation was permitted by the rules of the Illinois State Board of Health. The plaintiff claimed as damages the expense of transportation by carriage from Chicago to De Kalb, Ill., and the extra expense of preparing the corpse for transportation, in all some \$60. The facts being admitted, there was only a question of law involved, and that was—Whether the rule of the company forbidding the transportation of such a corpse was a reasonable one. Judge Smith held, as a matter of law, that it was a reasonable rule which the company had a right to make and enforce, and therefore the plaintiff had no right to recover damages.

**Contagious Diseases.**—The actual extent of the smallpox in Hot Springs and elsewhere in the lower Mississippi Valley can only be surmised; the sole sources of information, in the absence of official reports, are the newspapers and these vary widely—one recent account says there has been only a single case in the popular sanatorium and that convalescent, while, within forty-eight hours after, another asserts that there were forty-one cases under treatment at the beginning of the month. Quarantines are rife in Arkansas and Texas and travel has been somewhat impeded in consequence. The disease continues to spread in St. Louis and is reported subsiding in Chicago, Milwaukee and throughout the territory north of the Ohio River.

Influenza, diphtheria, pneumonia and bronchitis have increased in prevalence and severity since the first of the month. In this country, however, none of the diseases—except, possibly, diphtheria—is so prevalent or so severe as in Great Britain and on the Continent. Especially as to influenza, which, it is asserted, was never so widespread in any previous epidemic. In London, doctors and nurses have been peculiarly stricken, so that it has been almost impossible to secure medical attendance. The New York *Sun* correspondent says that one of his neighbors suffering with the prevailing distemper was attended February 27 by a physician; the next day the physician was ill and sent a substitute; the third day a third doctor attended, because the second had fallen a victim; on the fourth day, a substitute of the substitute sent a substitute, because the first three were all in bed. An Associated Press dispatch of the 2d inst. says the statistics of the Sanitary Bureau of Berlin show that three-fourths of all the sickness in that city at present is due to influenza. It is noted that the complaint, which was at first of a mild character, has grown much more dangerous, and the number of deaths from influenza and its complications during the week has reached several hundred. In the Reichstag the usual attendance dropped to about forty, some one hundred and fifty members either suffering or recovering from an attack. The total number of cases in Berlin is estimated at from thirty to forty thousand. We have had nothing approaching these figures in any American city, although the death roll of "old age" has been largely swollen by the disease.

During the first month of 1895, Asiatic cholera was reported in Austria-Hungary, Belgium, Brazil, France, Germany, Holland, India, Russia and Turkey. There were reported during that time 3,471 cases and 1,893 deaths. Sanitary Inspector Cleary, M. H. S., writes, under date Rio de Janeiro, January 22 (*Abstract of Sanitary Reports*, March 1), that the disease appears to be drawing to a close in the original localities in Brazil and the Argentine States, but is extending farther into the State of Minas Geraes, and down the Parahyba River to the north and is now in the neighborhood of Sao Fidelis, near its mouth. "The authorities are very energetic, and intelligently apply proper disinfections, isolations and removals in all suspected cases, and I believe that it is in consequence of these measures that this town is not as yet afflicted with cholera." Dr. Cleary adds: "I have never known a summer here with so few cases of zymotic diseases as this one; among the shipping there are none."

## BOOK NOTICES.

**A Manual of Diseases of the Ear** for the use of Students and Practitioners of Medicine. By ALBERT H. BUCK, M.D., Clinical Professor of the Diseases of the Ear, College of Physicians and Surgeons; Columbia College, New York; Consulting Aural Surgeon, New York Eye and Ear Infirmary, and the Presbyterian Hospital. Second revised edition, one volume, post octavo, 467 pages, illustrated, with blank memoranda pages at the back, extra muslin, price \$2.50. New York: Wm. Wood & Company. 1895.

This edition of Buck's excellent manual on diseases of the ear is well adapted for the use of students and general practitioners. A new chapter entitled "Analysis of Symptoms" has been added, and the section on chronic purulent inflammation of the middle ear has been re-written. The new chapter on "Analysis" occupies fifteen pages and it will be found extremely useful in diagnosis. "The list of these symptoms," says the author, "is not very long; it comprises impairment of the hearing, subjective noises, the phenomenon of hearing better in the midst of noise, the sensation of something moving in the head when the head is moved, a sensation of fullness in the ear, unnatural resonance of one's voice in the affected ear, pulsation or throbbing, itching, soreness or pain, painful mastication, discharge from the outer canal, dizziness, numbness, and possibly one or two others."

In suppurative disease of the mastoid antrum, the author says: "In all cases of comparatively recent origin, we must not forget one well established fact, namely, that the majority of them will, in one way or another, get well without operation." He admits the frequent formation of fistulae, and those accidents fatal to hearing which supervene on cases left to themselves, and he frankly admits that the chances of recovery without operation are very small in those cases where the cerebral complications are marked. In pyemic cases he considers operative measures urgent. Even in those cases of recovery without operation, convalescence has been so slow and tedious that operation would have been preferable. Explicit directions are given for trephining the mastoid antrum, and the author very properly, as we think, prefers the chisel to the trephine. He mentions after Macewen, accidents that have happened by improper or careless use of the chisel, such as hemorrhage from the sigmoid sinus, and rough fragments, both of which are to be avoided; the one by care and the other by the use of the rongeur to smooth the edges of the bony opening. The danger of opening the sinuss in these cases is not so much from hemorrhage (for that may be easily controlled by gauze packing) but from septic infection direct from the abscess cavity.

**Twentieth Century Practice**; an International Encyclopædia of Modern Medical Science by leading Authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D. In twenty volumes. Volume 1, Diseases of the Uropoietic System. Royal 8vo, cl., pp. 737. New York: William Wood & Company. 1895.

The nineteenth century is now so near its close that not much is probably required to anticipate the particular advances of the next four and a half years, but there is a possibility that there may yet be valuable discoveries added to the glorious record of the present century. This possibility has been recognized by the editor, who explains why, in the arrangement of subjects, the diseases of the uropoietic system occupy the initial volume. He says: "In arranging the order of subjects it has been thought best to reserve the consideration of infectious diseases for the later volumes in the hope that by the time they are published, a solution of some of the problems in the pathogenesis and therapy of these affections as yet but partially worked out, will have been reached."

The contributors to the present volume are Francis Delafield, M.D., LL.D., of New York, on "Diseases of the Kidneys;" Mr. Reginald Harrison, F.R.C.S., of London, on "Diseases of the Kidneys (Surgical) and of the Ureters," also "Diseases of the Bladder;" G. Frank Lydston, M.D., of Chicago, on "Diseases of the Prostate," and "Diseases of the Male Urethra;" Mr. E. Hurry Fenwick, F.R.C.S., of London, on "Diseases of the Urine," and Howard A. Kelly, M.D., of Baltimore, on the "Diseases of the Female Bladder and Urethra."

The tendency of the time toward operative interference in most diseases is here shown, as with the exception of Professor Delafield, all the writers in this volume are surgeons and write from a surgical standpoint. Mr. Harrison gives full credit to Van Hook and Finger, for their luminous expositions of the surgery of the ureters (published in full in this JOURNAL). In speaking of renal hydatids, he quotes Osler, of Baltimore, as saying that "it is rarely met with and in the inspection of over eight hundred bodies only three instances have been found." Hamilton's case (see this JOURNAL, Oct. 7, 1893) is not mentioned. The article of Dr. Kelly gives a full and very clear exposition of the methods of examination of the female bladder, and catheterization of the ureters. Dr. Lydston writes with his customary circumspection; in speaking of castration in prostatic disease he says:

"The most recent operation for the relief of enlarged prostate seems to be meeting with some success. The author has had no experience with it, but it is worth considering, provided the patient's virility has disappeared; otherwise it is better to construct an artificial supra-pubic urethra, with or without operation on the prostate proper. Castration is an operation not to be lightly undertaken as certain historical medico-legal cases have shown. Should future experience demonstrate that it is frequently successful, the surgeon should still exercise the greatest circumspection in the performance of this operation. A patient who appears perfectly reconciled to the loss of his testes may subsequently look at the matter in a different light; there is a suggestion of grim humor in the new procedure; the oöphorectomy craze of the recent past is still a vivid recollection."

#### **Materia Medica and Therapeutics for Physicians and Students.**

By JOHN B. BIDDLE, M.D. Thirteenth edition, revised, rearranged and enlarged, with special reference to therapeutics, toxicology, the physiologic action of medicines, and containing all the preparations and remedies described in the U. S. Pharmacopœia of 1890, to which the work has been made to conform. By CLEMENT BIDDLE, M.D., U. S. Navy, with numerous illustrations. Philadelphia: P. Blakiston, Son & Co. Chicago: E. H. Colegrove & Company. 1895. Price \$1.

So far as a notice can help or harm a book there is no particular use in a journalistic notice of Biddle's "Materia Medica," a book almost as staple as flour, and a title page as familiar to the profession as a picture of the front of the Capitol. It is sufficient to say that the thirteenth edition of this standard work has been revised to conform to the requirements of the new Pharmacopœia, and all its elements of popularity have been retained. We venture to suggest to the compiler of the fourteenth edition, that he give the dosage in the decimal or metric system in the text of the book as well as in the appendix. The publication of a posologic table in an appendix is valuable, as we can not have too much of a good thing, but the text of the articles itself should show this change of system.

#### **A Practical Theory and Treatment of Pulmonary Tuberculosis.**

By FRANK S. PARSONS, M.D., editor of the *Times and Register*. Paper, pp. 77. Philadelphia: Medical Publishing Company. 1895.

The author begins his brochure with the query whether pulmonary tuberculosis is curable, and answers it by saying "undoubtedly." He recommends proper individualization of cases and then oxygenation by hydrozone and glycozone, general treatment by climate, hygiene and exercise, diet

of carbohydrates, et cetera. The author has brought out his ideas in an attractive form, and his conclusions are logical. We notice also that it is being printed as a serial in the *New England Medical Monthly*.

**The Physician's Vade Mecum;** being a Handbook of Medical and Surgical Reference, with other useful Information and Tables. By SEBASTIAN J. WIMMER, M.A., M.D. With additions by FRANK S. PARSONS, M.D., editor of the *Philadelphia Times and Register*. Cl., pp. 483. Price \$1. Philadelphia: The Medical Publishing Company. 1894.

This is a convenient little book of reference for general practitioners and druggists. The "Physician's Interpreter," in English, French and German, is a new feature in a book of this kind, and a useful one. Some acquaintance with those languages is necessary in order to use the dialogue, as unless pronounced properly, the words will not be understood. There are over one thousand prescriptions in the book, all written in the old British system of weights and measures. A posologic table in another place, however, gives the decimal system of dosage.

## SELECTIONS.

**Echinococcus of the Right Ovary with Multiple Echinococci of the Peritoneum.**—According to W. A. Freund and Schatz, the development of echinococcus in the human ovary have not hitherto been proved. The seven cases collected from literature by Schatz are in his opinion not reliable; two other cases found by the writer speak with probability for echinococcus of the ovary. In one case of his own, which was operated on with good result, the writer attempts to prove that there was an autochthonous development of echinococcus in the ovary. The nature of the tumor was manifest from its smooth inner surface which was profusely covered with broad capsules and scolices, also from the daughter and grand daughter cysts inclosed in the tumor. The proof that the tumor was, in fact, ovarian, is derived from its position and its relation to the parovarium and tube. At no point in the tumor wall was ovarian structure demonstrated, a point which the writer asserts is an argument for his position that the echinococcus exercising like pressure on all sides, was developed in the midst of the ovary.—*Centralblatt für Gynäkologie*.

#### **The Practicability of the Murphy Button for Anastomosis.**

Chaput has stated his opinion before the *Société de Chirurgie* on the usefulness of the Murphy button as follows: "On the cadaver the largest sized button in ten cases out of twelve could pass the jejunum only with the greatest difficulty; twice it was altogether impossible. The cause lies in the lumen of the bowel, which, in eight cases, yielded the following figures: 41, 27, 27, 26, 45, 37, 27 and 21 mm., and in four cases, inflated, 100, 70, 73 and 68 mm.; on the other hand, the circumference of the Murphy button shows the following measurements: 66, 78.5 and 84 mm. Accordingly the bowel is absolutely too narrow for the highest two numbers. On the basis of these experiments, Chaput states the following opinion, that the use of the highest two numbers, if it is to pass the jejunum, is directly contrary to common sense and that even the lowest can possibly catch at the end of the ileum.

"In eight experiments on dogs, he had the following results: Four recoveries and four deaths. In two favorable cases the expulsion of the button took place on the eighth day, in two others the buttons remained *in situ* when the animal was killed. The Murphy procedure does not induce stenosis of the bowel. Of the four other dogs, three died of peritonitis with necrosis of the intestine; in the four gastroenterostomies the gut slipped out from the button and the intestinal contents were discharged into the abdominal cavity.

In man, Chaput had the experience once of finding that the ends of the rectum, resected for carcinoma, could not be brought together with the button; in another case, after resection of the ascending colon, the patient died in forty-eight hours, and at the post-mortem the bowel was found almost perforated, and the lumen of the button obstructed by a hard fecal mass.—*Centralblatt für Chirurgie*.

**Cystitis in the Female.**—The *Wiener Klinische Rundschau* has the following abstract of a paper by Dr. Zuckerkandl: "Granting the fundamental fact that, as a rule, the simple admission of pathologic germs into the bladder is not followed by inflammation, but that in some way an abnormal condition of the bladder wall must be created, the writer distinguishes in the female:

"1. Cystitis from hyperemia of the bladder. Between the fundus of the bladder and the uterus there exists a connection in blood supply. Therefore it happens in the gravid state that various inflammatory processes in the uterus and its adnexa, and other conditions which follow congestion, are accompanied as well by hyperemia of the bladder wall. On this soil a cystitis is easily induced, spontaneously, if germs pass from the urethra into the bladder, as quite frequently happens in catheterization. Cystitis also arises from hyperemia of the bladder in conjunction with the operative separation of the posterior wall of the bladder.

"2. Cystitis from insufficiency: *a*, from malposition of the bladder lateral version, prolapsus descensus vesical, and tumors, which render it impossible that the bladder contracts normally; *b*, from retention post-partum in consequence of the softening of the mucous membrane; *c*, from involution of the bladder. In old women who have borne many children, the bladder is dilated, the mucous membrane becomes atrophied, thin and pale and the sphincter and detrusor become insufficient. (Chevalier, in 1891, portrayed a similar condition as prostatism in the female.)

"3. Traumatic cystitis, for example, necrosis from pressure in childbirth."

The writer further made mention of the transmission of pathogenic germs from neighboring organs, for example, the intestines into the bladder, and the possibility of accompanying hyperemia. The spontaneous migration of germs from the urethra naturally does not act as an opposing factor; on the contrary, in doubtful cases an antiseptic injection should follow catheterization.

In the discussion that followed, Dr. Mackenrodt (Berlin) combated the idea of a connection between the bladder and the uterus through the larger arteries, and even a capillary connection; in the separation of these organs from one another, neither any considerable hemorrhage, nor a disturbance of circulation takes place. During pregnancy the blood pressure is increased in all the abdominal organs, consequently in the bladder. As an etiologic factor in cystitis he would further mention the sacculation which is observed not merely after laparotomy, but especially in pelvic peritonitis.

In closing, Dr. Zuckerkandl stated he had at the last moment forgotten to mention in his paper these shrivelling processes, as results of pelvic peritonitis. He insisted that a connection in the blood supply between the bladder and the uterus does exist and is formed through venous trunks, three or four of which, on each side, run backward from the posterior wall of the bladder in the loose cellular tissue.

**The Forty-sixth Annual Session** of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

## SOCIETY NEWS.

**Kings County (N. Y.) Medical Association.**—I desire herewith to notify you officially of the duly elected officers of the Kings County Medical Association, of New York, for the year 1895: President, J. C. Bierwirth; Vice-President, N. W. Leighton; Recording Secretary, F. C. Raynor; Corresponding Secretary, H. C. Riggs; Treasurer, E. H. Squibb. Elected members of the Executive Committee: Jonathan Wright, term expires January, 1896; J. D. Rushmore, term expires January, 1897; R. M. Wyckoff, term expires January, 1898; T. M. Rochester, term expires January, 1899. H. C. Riggs, M.D., Corresponding Secretary.—The first meeting

of the Southwestern Medical Association was held in Creston, Iowa, February 26.—A regular meeting of the St. Louis Medical Society was held February 23.—The Luzerne Medical Society held a meeting February 20.—The Northern Berkshire Medical Association held a regular meeting at North Adams, Mass., February 24.—The third annual meeting of the Austin Flint Medical Association of Lawrenceville, Pa., was held February 26.—The quarterly meeting of the Onondaga County Medical Society was held February 26, at Syracuse, N. Y.

## MISCELLANY.

**Busy Bacteriologists.**—A Berlin letter of the 20th ult., says that the scientific men of the day who are making investigations in bacteriology are as feverish as were the prospectors for gold in California half a century ago. They all feel themselves on the eve of great discoveries, especially since Behring hit upon his *heilserum*, the panacea for diphtheritic troubles. The laboratories of Pasteur and others of eminence are already crowded, and the young men who go to Paris hoping to gain admittance into such workshops must have done enough in bacteriology to warrant the expectation that they are to become shining lights in the scientific world.

**Mortality by Influenza Influenced by Humidity.**—Sergeant Dunn, of New York City, holds the opinion that a marked relation subsists between the prevalence of certain types of weather and the prevalence of grip. His conclusion is that the weather is an important factor in the mortality of grip cases and that the humidity of the air "seems to be the important element in producing or aggravating the disease." He says: "The fatality is most marked when the humidity is at its maximum and there is a sudden fall of temperature. . . . The higher the humidity and the more sudden the fall of temperature the greater the number of deaths, and it is also observed that when the temperature and humidity drop at the same time there is a sudden decrease of the death rate."

**The Health Officer of New York.**—Dr. Alvah H. Doty, the newly appointed Health Officer of the Port of New York, is probably the youngest man to receive that important command. He was graduated from Bellevue Hospital Medical College in 1878. He was soon thereafter appointed Diagnostician to the Contagious Disease Bureau of the Board of Health; of which he has been Chief Inspector during the past year or two. He has manifested great vigor in the handling of the metropolitan problems in contagious crises. He has acquired a volume of experience that will not fail him in any peril that may approach the great harbor over which he will be sanitary autocrat. Like sundry other sanitarians of his State, he has entered the surgical arm of the National Guard, being Surgeon and Major in the Ninth Infantry Regiment.

**Some New Properties of Pilocarpin.**—Hartcop calls attention in *Les Nouveaux Remedes* to pilocarpin, which, in his opinion, is unjustly abandoned as a medicament. It renders signal service, especially as a sialogogue. He gives it subcutaneously in doses of 0.01 to 0.02 grammes. It can be used with great benefit first in intracranial hyperemia, uremia, commencing meningitis, chronic meningitis; next in affections of the throat and larynx, especially in edema of the glottis; then in acute renal affections, scarlatinal nephritis and in some affections of the cord and peripheral nerves in the initial stages. Pilocarpin also acts as a revulsive. In some cases it is advisable to associate it with iodid of potash or the biniodid of mercury. The author reports several cases in support of his assertions.

**Cleansing the Surgeon's Hands.**—There are three principal methods of cleansing the surgeon's hands in vogue in Germany. The one most commonly employed is that of Fürbringer, which consists in brushing the hands and nails with soap and hot water, then dipping them in an 80 per cent. alcohol solution, and finally washing with a 2 per cent. sublimate of mercury, each part of this proceeding to last one minute. Reinecke, of Leipzig, asserts that a sure disinfection of the hands may be obtained by rubbing them with alcohol only and washing afterwards with pure sterilized water; the alcohol dissolves the sebaceous substance on the surface of the skin, thus enabling the bacteria which adhere to it to be easily washed away. Schleich rejects all brushing, and only washes the hands with a soap invented by himself, which consists of domestic soap (one part), marble powder (three parts), and lysol (4 per cent. of the whole); this soap cleans less by chemist than by mechanical means, the fine marble powder penetrating into all the folds of the skin and rubbing away all dirt and detritus.

**Alcoholism in Russia and Switzerland.**—A new law regulating the sale of alcoholic drinks has been in effect since the first of this year in some parts of Russia. It received the imperial sanction June 6, 1894, and it is believed by the *Gazette Medicale de Liege* that it will undoubtedly diminish the consumption of alcohol. It is now in effect in the provinces of Perm, Oufa, Orenburg and Samara. Committees, comprised of the principal men of the locality who are best acquainted with the habits of the community, are constituted in each village and are to be known as "Guardians of Temperance." Their duties will be to aid the State in reforming the sale of alcoholic drinks, to make the dangers of alcoholic abuse known by local conferences, and to establish temperance cafés where men may find the attractions usually inseparable from alcohol. Switzerland is the best organized country for the contest against alcoholism. On Sept. 30, 1893, the Society of the Blue Cross numbered 241 groups with 11,143 members, 4,118 of whom were reformed drunkards. Its activity is unrivalled, favored as it is by the strict legislation governing the sale of alcoholic drinks in Switzerland. It has founded temperance cafés in Geneva and several other large cities and several have been started by private parties as a speculation.

**The Forty-sixth Annual Session** of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

**An International Language for Medicine.**—Dr. Manassein, of St. Petersburg, is in favor of adopting French as the international language for medicine, which prompts Dr. Keser to write to the *British Medical Journal* giving some reasons for this adoption. After disposing of Latin, Greek and German he adds: "We are thus limited to English and French. English is a simple and useful language, probably the best for written communications, but it is much more difficult to understand and to speak than to read and write. As a means of international communication orally, English is decidedly inferior to French, the pronunciation is very difficult and the clear production of its sounds requires considerable effort. French is already the universal language of the diplomatic corps. If I may judge by frequent meetings with foreigners, it is in more universal use than English among physicians in Russia, Germany, Spain, Italy, South America, Greece and Turkey. No language compares with it for clearness and precision. The use of French is widespread in England, where it is positively rare to find an educated physician without some knowledge of it. Most of them make excellent scholars without much difficulty." Keser concludes: 1, it is highly desirable in the interests

of science that some agreement should be reached as to the adoption of an international medical language; 2, no language, living or dead, meets the necessary requirements better than the French.

**The "Percentage" Slander Repudiated.**—A member of the New York Academy of Medicine has recently written a letter to the *Herald* of that city, to show how slanderous is the view held by some, that all druggists pay physicians a percentage on all prescriptions. The letter was elicited by an alleged humorous paragraph, in a former issue of the *Herald*, declaring that "the doctor draws a fat commission from the till of his accomplice, the apothecary." As the writer remarks, no good end is met by the publication of slurs of that kind; what little effect they have is all in the wrong channel. They simply tend to confirm an unjust prejudice unwisely accepted by ignorant laymen. The letter states that in two decades of active practice he never met with one such commission-paying druggist. The following is a part of the letter: "I have practiced medicine for more than twenty years and I am happy to say that no such offer has ever been made to me. A physician's reputation and success depends not only upon the skill with which he prescribes, but quite as much so upon the care and accuracy with which his prescriptions are dispensed; and hence he recommends his patient to a certain drug store, or a choice of certain drug stores, where he is sure the conditions will be fulfilled, and he warns them against other stores of a less respectable and frequented class, where unqualified boys are allowed to handle important drugs, where it would be practically impossible to maintain a full line of drugs in good condition and where if they do not happen to have the article called for they do not hesitate to substitute something else."

#### Hospital Notes.

A PUBLIC HOSPITAL at Muskegon, Mich., was organized February 26. Charity clinics will be held weekly, and a training school for nurses will be organized in connection with the hospital.—A new hospital for scarlet fever and diphtheria cases will be established in New York, owing to the beneficence of Mrs. John W. Minturn, of that city, who has given \$25,000 toward the erection of an institution for that purpose.—The annual report of the German Hospital at Kansas City, Mo., shows that 321 patients have been treated during the year.—The executive board of the Buffalo General Hospital have approved the plans for the new hospital building in that city, cost not to exceed \$150,000.—Plans have been prepared for the new St. Joseph's Hospital for the Insane at Asbury, Iowa. The building will accommodate 210 patients and will cost nearly \$75,000.

#### Louisville Notes.

**VITAL STATISTICS.**—Flemming County, Kentucky, is one of the few counties in the State in which there is a law making it compulsory for a return to be made by the physicians, of all births as well as deaths. During the past year this has not been done, and on March 1, warrants were issued for every doctor in the county for failing to register a list of births and deaths during the year.

**LEXINGTON'S SMALLPOX.**—Just when the public mind became at rest over the subject of smallpox in Lexington, there was developed a municipal scandal in regard to the purchase of the pest-house by the city.

**AMBULANCE.**—The importance of a city ambulance is shown by the report of its excellent service for the past month. The ambulance is kept at the City Hospital and is free for the transportation of the sick or wounded to their homes, the infirmaries, or the City Hospital.

**MORTALITY REPORT.**—The fatality of pneumonia during February is unprecedented in this city. It is impossible to gather any statistics as to the death rate of the total number of cases, but this can be conjectured from the fact that only three recovered out of fifteen cases at the City Hospi-

### SKETCH OF THE MEDICAL BUREAU WORLD'S COLUMBIAN EXPOSITION.

BY JOHN E. OWENS, M.D.

MEDICAL DIRECTOR OF THE MEDICAL BUREAU OF THE  
WORLD'S COLUMBIAN EXPOSITION.  
CHICAGO, ILL.

#### ROSTER.

*Medical Director.*—Dr. J. E. Owens, June 1, 1891, to March 31, 1894.  
*Attending Physicians.*—Drs. N. E. Yeager, June 1, 1891, to Nov. 30, 1893; W. H. Allport, June 1, 1891, to Nov. 30, 1893; S. C. Plummer, August 1, 1891, to Nov. 30, 1893; G. P. Marquis, Jan. 1, 1892, to March 1, 1893; E. T. Edgerly, Feb. 1, 1893, to Nov. 15, 1893.  
*Resident Physicians.*—Drs. J. L. Hillmantel, April 10, to Nov. 30, 1893; D. M. Appel, Captain and Ass't. Surgeon, U. S. A., May 1, to May 17, 1893; W. C. Raughley, May 17, to Oct. 30, 1893.  
*Hospital Steward.*—William Kelly, April 7, to Dec. 20, 1893.  
*Druggists.*—Harry Kahn, April 16, to Sept. 1, 1893; F. C. Cady, Sept. 1, to Nov. 16, 1893.  
*Superintendent of Nurses.*—Mary R. Browne, March 16, to Nov. 30, 1893, (St. Luke's Training School, Chicago).

#### TRAINED NURSES.

Harriet Fulmer, Anne Northwood, March 15, to April 15, St. Luke's, Chicago.  
Karin Eckstrom, March 15, to November 15, Stockholm, Sweden.  
Helen Parr, April 16, to August 1, Louise Richey, August 1 to December 1, St. Luke's Chicago. (Surgical Nurses).  
Bessie Woolfings, May 1, to June 1, Guy's Hospital, London, Eng.  
Emma Dawson, May 1, to June 15, St. Luke's, Chicago.  
M. McDonald, E. McDonald, May 15, to June 15, Boston City Hospital.  
M. Clark, A. Smith, May 15, to June 15, Massachusetts General Hospital.  
Mary Forbes, June 1, to August 15, St. Luke's, Chicago.  
Muriel Moberly, different terms between June 15, to November 15, St. Luke's, Chicago.  
Helen Wiltzie, June 15, to July 15, St. Luke's, Chicago.  
Susan Read, Mary Townsend, June 15, to July 15, Johns Hopkins Hospital.  
Catherine DeWitt, Eliza Moore, June 15, to July 15, Illinois Training School.  
Clara E. Parsons, Marie A. Lawson, July 15, to August 15, Michael Reese Hospital.  
Anna Bartle, July 15, August 15, Toronto General Hospital.  
Alice Cooper, Lockhart Baillie, July 15, to August 15, Bellevue Hospital.  
Bessie Woffendin, August 15, to September 15, Toronto General Hospital Toronto, Canada.  
Alice Buckman, M. L. Van Thynne, August 15, to September 15, Philadelphia Hospital.  
I. C. Mathis, A. N. Bartholomew, August 15, to September 15, University of Pennsylvania Hospital.  
Ruth Williams, Helen Barnard, September 15, to October 15, Johns Hopkins Hospital.  
Martha Munn, Margaret Munn, September 15, to October 15, New York Hospital.  
Virginia Williams, August 15, to October 1, St. Luke's, Chicago.  
Mary Shears, July 15, to October 1, St. Luke's, Chicago.  
Agnes McCoy, July 15, to September 15, St. Luke's, Chicago.  
Gertrude Philipotte, September 15, to November 15, St. Luke's, Chicago.  
Pauline Hollenbeck, Florence Bell, October 1, to November 15, St. Luke's, Chicago.  
Elizabeth Pope, October 1, to November 1, St. Luke's, Chicago.  
Margaret M. Watson, Annie Louise Higgins, October 15, to November 6, St. Luke's, New York.  
Nettie West, October 15, to October 30, Michael Reese Hospital.

*Superintendent of Ambulance Service.*—H. W. Gentes, M.D., April 10, to November 30, 1893.

*Superintendent of Ambulance Corps.*—J. F. Minot, April 10, to November 12.  
*Ambulance Corps.*—C. L. Hammond, W. K. Hammond, H. A. Adams, John T. Hitecroft, C. Brooker, J. S. Brown, Edgar Thomas Lucas, M. E. Wheelan, J. H. Missey, A. M. Schahad, J. M. Smith, L. M. Dunavan, J. C. Egan, E. B. Hutchison, H. G. Graham, H. B. Bartholomew, W. B. Robinson, C. W. Culp, Fred Herr, J. L. Allen, T. H. Little, M. G. Bryan, Morgan Savidge, J. W. Walker, C. E. Downey, L. W. Dunavan, and others.  
*Ambulance Drivers.*—M. J. Sanborn, F. H. Crein, E. J. Pettinger, D. M. Good, J. H. McLernon, J. W. Tarbell, J. E. Price, and others.  
*Orderlies.*—Claus Williams, A. H. Kennedy, Chas. Webster, N. K. Derderian, J. E. Johnson.

*Chief Sanitary Officer.*—D. M. Appel, M.D., May 17, to July 26, 1893.  
*Sanitary Inspectors.*—J. H. Kellogg, Mary Glennon, Anna Byford Leonard.

*Recording Clerk.*—Alexander Goldstein, May 8 to first week of December.  
*Stenographer and Typewriter.*—Anna H. Newton.

*Messenger.*—Frank Frisbie.  
*Telephone operator.*—Robert Rozeine.

*Janitors.*—A. U. Brown, George Blakey, E. Fleming, and others.  
*Ward maids.*—Christine Webster, Anne Boettner, Rachel Ellingston.

#### DEDICATION DAY AND THE DAY FOLLOWING.

Drs. E. T. Edgerly, Jennie Hayner, Bertha Van Housen.

*Trained Nurses for the Hospital (Dedication Days).*—E. Farrow, M. Moberly, E. Dawson, E. Jackson, C. Fowler. *Ward maid.*—Rachel M. Vicker.

*Trained Nurses at the two Substations in Manufacturers Building.*—M. R. Browne, Louise Richey, M. Bryce, R. A. Ellerby.

*Orderlies at Hospital.*—H. T. Haas.  
*Orderlies at Substation.*—J. W. Walker, O. O. Witherbee.

*Ambulance Surgeon.*—Dr. G. F. Marquis.  
*Litter Bearers on Ambulance.*—J. A. Pohliug, C. Ehling.

#### ORGANIZATION.

The last week in May, 1891, the Committee on Grounds and Buildings established the Medical Bureau, and, after a conference with Mr. E. T. Jeffery, Chairman of said Committee, the position of chief medical officer of the Exposition Company was accepted. On May 29 the following general arrangement was agreed upon and approved:

That the title of the chief medical officer should be "Medical Director;" that the appointment be effective June 1, 1891; that the Medical Director shall have authority to appoint, subject to the approval of the Committee on Grounds and Buildings, such assistants as he may deem necessary for efficiency in organization and the prosecution of the work.

The duties of the Medical Director were thus formulated: To organize a medical bureau having jurisdiction over all cases of personal injury occurring in the line of duty; to assume the care of the resident population and visitors, and such other cases as the Exposition Company might be responsible for, or in its judgment should be cared for; to exercise a supervision over all sanitary and hygienic matters connected with the grounds and buildings, and over all matters pertaining to the health and physical well-being of the construction employees engaged in the conduct of the Exposition.

In the pursuance of some of the foregoing objects, it was decided to establish a temporary hospital upon the grounds and afterward, as circumstances might require, and after conference with the Committee on Grounds and Buildings and the Construction Department, to construct a building better suited to meet the exigencies of the Medical Bureau.

The Medical Director was instructed to report to and receive his instructions from the Committee on Grounds and Buildings, and to confer from time to time, as circumstances might suggest, with Mr. D. H. Burnham, the Chief of Construction, or his representatives, in order that coöperation might be secured in accomplishing the purposes in view.

It was agreed that the Medical Director should keep such reports and data regarding his bureau as would enable him to make monthly reports to the Committee on Grounds and Buildings, and a final report at the close of the Exposition.

Blank pay rolls, vouchers and other stationery required were furnished on the order of the Medical Director upon the Grounds and Buildings Committee.

A monthly pay roll for himself and assistants was made by the Medical Director, and the same trans-

mitted to the Committee on Grounds and Buildings; and, at the same time, duly certified bills and vouchers for expenses. The attending physicians treated all cases of illness and injury brought to the emergency hospital, and devoted more or less time to sanitary inspection during the construction period. The grounds were districted in order to facilitate this work.

The large resident population, together with the great number of workmen about the grounds at all times, necessitated the appointment of resident physicians who lived in the emergency hospital. As these gentlemen were required to reside in the hospital they could not, therefore, engage in private practice. The duties pertaining to the office of resident physician consisted for a time in the inspection of grounds and buildings; care of the resident population; they were responsible for the efficiency of the hospital service; for the conduct of the hospital in general during the absence of the Medical Director; they furnished a report of deaths, weekly and daily reports of the work performed and, as occasion required, they aided the attending physicians in the performance of their work.

It gives me pleasure to testify to the ability with which both attending and resident physicians performed their onerous duties; to their loyalty to the service; to the promptitude with which they filled their daily appointments and to the courtesy and helpfulness extended to the sick and injured. All of this largely contributed to the success of this department of the Exposition.

On July 15, 1892, the Medical Bureau was placed under the auspices of Mr. D. H. Burnham, Chief of Construction.

#### BUILDINGS.

For the beginning of the dispensary work, temporary quarters were at once secured in a corner of a room then used by the Construction Department. Soon after, a one-story building was erected, consisting of a waiting room, a sleeping room, an operating room and a store room. This was speedily equipped and occupied July 20, 1891. The hospital was soon after erected, and formed a part of the Service Buildings at Sixty-second Street. Sept. 3, 1892, we moved into this building, but it was at that time mostly occupied by a portion of the clerical force of the Construction Department. Work began here in four rooms. Oct. 19, 1892, the south wards were made available—one for men and the other for women. Feb. 1, 1893, the operating room was secured. April 24 to 28, 1893, the north wards were evacuated by the clerical forces, and still later, the room occupied by the telegraph operators.

The emergency hospital contained on the first floor the following: Two wards of ten beds each for men; one ward of ten and another of three beds for women; Medical Director's office; resident physicians' office; attending physicians' office; office of the Superintendent of Nurses; a diet kitchen; drug room; linen and clothes closet; two examining and operating rooms and closets; reception room and two waiting rooms—one for men and one for women. In addition to the beds above noted, ten rattan lounges were distributed about the wards and corridors. On the second floor were the dormitories for nurses, resident physicians and druggist. No meals were served in the hospital for either patients or staff, but in the diet kitchen the nurses prepared soups, teas and refresh-

ing and stimulating delicacies. It was a rare exception to keep a patient over night.

In cases where transportation of patients to the hospital is rendered difficult or impossible in consequence of dense crowds, temporary substations or portable hospitals should be established. From five to ten beds in each, according to circumstances, would be sufficient in most cases. They answer admirably, provided precautions be taken to prevent the demand from over-reaching the capacity. On such occasions even the passage of carriages through the street on their way to the hospital for the purpose of conveying patients to their homes, railway stations, or hotels, was extremely difficult and time-consuming.

On Chicago Day when there were 716,881 paid admissions, the Exposition being open both day and night, the necessity for these extra provisions was very great.

#### TRAINED NURSES.

The desirability of employing only trained nurses for the emergency hospital was apparent from the outset, but the expenses pertaining thereto would have been considerable at the ruling rates in this city. The scheme finally adopted was as follows: To offer an opportunity to the leading training schools in the country for the representation of their schools by the sending of two trained nurses to serve thirty days at \$25 a month, with allowances, such as board, lodging and laundry service. This offer was readily accepted. The nursing force was placed in the charge of Miss M. R. Browne, a graduate of St. Luke's Training School for Nurses, Chicago. Her title was "Superintendent of Nurses." Her appointment was made effective March 15, 1893. Exclusive of the superintendent, at first there were ten nurses, one of whom was called "the surgical nurse." The latter had charge of the operating room and the preparation of instruments for operations, and when on duty, was always in service at the operating table. Each nurse was on duty eight hours and off sixteen hours. In this way they were able, while giving their schools representation in the work, to study the Exposition and at the same time render us that skilled service which is now so much in demand in our own and other countries. They remained in service from 8 A.M. until 11 o'clock at night. After that hour a sufficient force was always available at the hospital at a moment's notice, however great the demand. The following institutions were represented: Bellevue Hospital, New York Hospital, St. Luke's Hospital, New York; Philadelphia Hospital, Hospital of the University of Pennsylvania, Johns Hopkins Hospital; St. Luke's Hospital, Chicago; Michael Reese Hospital, Illinois Training School, Massachusetts General Hospital, Boston City Hospital; Guy's Hospital, London, England; one in Stockholm, Sweden, and Toronto General, Canada. We had a greater number from St. Luke's Training School, Chicago, than from any other, and made a point of keeping a nucleus of nurses from that institution, familiarized with the work. After the first month, in addition to the Superintendent of Nurses, we never exceeded twelve on duty at one time, except during three or four weeks subsequent to the Cold Storage disaster, when fourteen nurses were required. By common consent four nurses were known as "the pioneer nurses," namely Miss M. R. Browne, Superintendent, and the Misses Fulmer, Eckstrom and Northwood. These, under the guid-

ance of their able superintendent, in a building at that time a notable thoroughfare and well filled with officers and clerks whom we often despaired of dislodging, in the midst of the legitimate professional work then going on, including the examination of many hundreds of guards, without exaggeration, absolutely quarried their way through many obstacles and eventually there appeared a hospital that we believe was pleasing to all.

As attachés of the nursing force there were four orderlies and two ward maids. Their duties consisted of stretcher work, lifting patients, assisting in the examining room, cleaning, etc. In addition to these, four colored janitors took care of the building and kept the drug room in order. Two telephones—one for "long distance" and one for "short distance"—were early found necessary.

When fully equipped, the personnel of the emergency hospital consisted of the following: Two resident and four attendant physicians, a superintendent of nurses, with a corps of twelve trained nurses, four orderlies, a druggist, a recording clerk, a messenger boy, a telephone operator, four janitors and a hospital steward, who had care of the property, records, reports, and who transacted the general business pertaining to the Medical Bureau. For a time daily, and on all special occasions, when the crowds were the greatest and the demands upon the hospital were proportionately increased, Columbian guards were detailed for service at the entrance of the hospital.

All were uniformed—the physicians in navy blue, the orderlies and litter bearers in gray and the nurses in the uniforms of their respective schools, except the superintendent of nurses who wore white.

A general kitchen was not included in the plan, and therefore no meals were served in the hospital. The nurses ate at the officers' mess at hours specially fixed. The diet kitchen was used solely for the preparation of special diet for the sick and injured. It was a rule of the department that patients should not be kept over night. Exceptions were made only when absolutely necessary.

#### AMBULANCE SERVICE.

During the pre-Exposition period the sick and injured were transported in patrol wagons. At the dedicatory and opening exercises, as well as on other occasions where the people were densely massed, invalid chairs, marked with a conspicuous red cross on white background, in charge of trained men, were stationed on the outskirts of the crowd. Sometimes, the location of the chairs was indicated by means of a very large red cross on a sheet on the sides of the building and above the level of the crowd. The work of the ambulance corps proper began on May 1, with the opening of the Exposition. At first, four ambulances were put into service, but the exigencies did not seem to require the fourth one and its use was discontinued. In less than fifteen seconds after a call had been received a wagon was ready for the start. The ambulance corps numbered twenty-five men (litter bearers), exclusive of their sergeant, J. F. Minot, and nine drivers. The latter were not allowed to leave the box. Dr. H. W. Gentles, the superintendent of the ambulance service, received his instructions from the Medical Director. Dr. Gentles thoroughly drilled the ambulance corps in "first aid," and performed his duties in a very able

manner. He had had, previous to his appointment, much experience in this kind of work. The greater proportion of the litter bearers were young medical men who had had more or less experience as hospital internes; some had seen service in the Army Hospital Corps; others were medical students, and all were well fitted for this special branch of the service.

Quick transportation through large crowds was a matter of extreme difficulty. This was avoided occasionally by the use of the Ashford Wheeled Litter, loaned by the St. John's Ambulance Association. This litter and the invalid chairs above mentioned were of great service in moving patients either through large buildings or through dense crowds to points where the ambulances could continue the transportation to the emergency hospital. The principal days on which these precautions were found necessary were the Opening Day, Infanta's Day, the Fourth of July, Rajah's Day, Illinois Day and Chicago Day. The system of communication between the sick and the ambulance was as follows: A friend of the sick person called the nearest guard, who telephoned by means of the nearest patrol box his desire for an ambulance and, if possible, the nature of the case. The call on being received by the central office was transferred to the nearest ambulance station, and the ambulance wagon immediately took the shortest and most unfrequented road to the box. It was the duty of the guard to remain at the box until the ambulance wagon arrived in order to direct the bearer to the case, which was then, after the immediate indications were fulfilled, removed to the hospital. On days when there were especially large crowds, men were stationed at certain boxes marked by large red cross flags. In this way, any person who had a sick friend had no difficulty in knowing where assistance was to be received. After patients had been treated at the hospital the ambulances were frequently called into requisition, either to transfer a patient to his home, to his hotel, or, again being placed in a rattan basket stretcher, he was sent by rail to the point nearest his home or hospital, and there the city police ambulance or patrol wagon completed the transportation. The men remained on duty eight hours, there being three reliefs in the twenty-four hours. The ambulances were in service from 8 in the morning till 11 o'clock at night, and longer when necessary. One wagon, that was nearest the hospital, remained on duty twenty-four hours, so that a constant ambulance service prevailed. Two drivers were assigned to each wagon, with the exception of the hospital ambulance, which had three—two during the day and one at night. Each of two wagons had an assignment of one pair of horses. The hospital ambulance had two pairs, and in the event of any sickness among the horses, substitutes were easily obtained. The ambulance corps had several calamitous accidents to take charge of—three in particular. The fatal Cold Storage fire occurred July 10. On this occasion twenty-two cases were brought to the hospital in a very short space of time. The men also, in addition to their ordinary duty, remained at the scene of the fire and took care of any trivial accidents incident to the occasion, and also supplied coffee, sandwiches, etc., to the workers. On June 28 a floor gave way in one of the temporary buildings and injured a considerable number of people. Thirty of these were taken care of by the ambulance corps. On the occasion of the accident

on the ice railway the sufferers were removed quickly and with dispatch to the hospital. On July 4, 70 calls were answered; in May, 315; in June, 406; in July, 581; in August, 564; in September, 605; on Chicago Day (October 9), 172. One ambulance was stationed at the hospital building; another contiguous to Terminal Station, Machinery Hall, and the Grand Plaza, and a third at the east end of Midway Plaisance, convenient to the north end of the grounds. While there were a number of narrow escapes, no visitor or employee was actually struck by either horse or ambulance. The latter carried, in addition to splints and litter, a bag with all necessaries likely to be called for in an emergency case. Moreover 150 light stretchers, with a single blanket for each, were enclosed in white canvas bags marked, "Stretcher" and placed in conspicuous places in the chief buildings, to be used in the event of a great accident. These were easily obtained.

#### RULES FOR AMBULANCE SERVICE.

1. All calls are to be taken on the telephone by No. 1, who shall repeat the message over again to the operator.
  2. No. 1 shall in all cases inform the driver whether there is any special reason for haste.
  3. On receipt of a call, the wagon is to leave the station in the shortest possible time. All unnecessary bustle and noise is to be avoided.
  4. The driver shall always take the most unfrequented and shortest route to and from an accident. No driver shall use the gong when not necessary, but if path is crowded he is to keep going so that everybody has sufficient time to get out of the road. The gong must always be rung before turning a corner. All guards or guides shall do everything in their power to facilitate the progress of the wagon whether they be on duty or off.
  5. The man on the wagon must always report the name and number of any guard who does not assist in clearing the way for the wagon; also any person, carriage or chair so placed, driven or wheeled as to obstruct the passage for the wagon.
  6. All reports are to be handed in (in writing) as soon as possible to the Superintendent of Ambulance, so that he may investigate the report and forward the result to the Medical Director for instructions.
  7. If, on arriving at the place from which the call has been sent, there is nobody at the box to direct the ambulance men this fact must be reported at once to the Superintendent.
  8. All members of the corps *must* show the utmost consideration to sick and injured persons and their friends, especially ladies. They shall always try to accommodate one of the patient's friends inside the wagon; otherwise nobody is to be allowed to be inside or on the steps of the wagon.
  9. Men off duty are *never* to ride on the wagon.
  10. The ambulance of the Bureau, while engaged in going for or in carrying sick or wounded persons to or from the hospital or substation, shall have the right of way, excepting fire apparatus responding to alarms of fire, against any person, carriage or incumbrance, put, driven or being in streets, and no person shall obstruct said ambulance while so engaged if there shall be an opportunity to get of the way.
- By the courtesy of the Chief of Police of the city of Chicago, Major McLaughry, this rule holds good

outside the grounds, and city police officers have instructions to give ambulances of the Bureau the right of way in the streets of the city of Chicago.

Approved.

JNO. E. OWENS, Medical Director.

D. H. BURNHAM, Director of Works.

#### WATER.

The statistics of the Department of Health of the City of Chicago showed, to February, 1892, a very serious death rate from typhoid fever, the number of deaths from this cause for the year ending Feb. 29, 1892, being nearly two thousand. After this date the water supply of the city was much improved by the extension of tunnels. The general supply of water for the city, contiguous to the Exposition grounds, was obtained from the lake through the pumps at Hyde Park Station at 68th Street. The supply to the grounds was independent of that to the city, and furnished by means of pumps erected at Hyde Park Station by the Exposition Company, and to be taken by the city, after the close of the Exposition. The amount of water which could be pumped was 24,000,000 gallons daily, but the domestic consumption on the grounds averaged about eight million gallons per day. The extension of the tunnel into the lake had not been completed, and pure water for the workmen became a desideratum. As soon as practicable, arrangements designed and constructed by Mr. W. S. MacHarg, Engineer of Water Supply, Sewerage and Fire Protection, were completed for the supply of sterilized water for the use of constructionists and others. The method of preparing the drinking water was as follows: Adjacent to the boiler room at the temporary power house four tanks were set, the number being afterwards increased to seven, graded and elevated so that there was a difference of level between each successively. Each tank was seven feet in diameter and nine feet high and made of cypress. The upper tank was used for cooling, and a coil of inch pipe was placed in it, delivering at the top on a pan from which the water flowed in a thin sheet into the next tank below and overflowed through a pan in the same manner to the successive tank. The water was thus aerated and cooled at the same time. A feed water heater was set in the boiler room, and the water delivered under pressure through this heater into the coil, the steam in the heater being at ninety pounds pressure, and the water supply throttled so that a temperature greater than 212 degrees Fah. was obtained. From the lowest tank the water was drawn off at a point about two feet above the bottom into tank carts for delivery on the ground. At this time there were forty-one barrels or casks in service, with an additional thirty-five for use whenever required by any increase in the force. Each of the barrels was emptied and refilled daily, without regard to the amount of water it may have contained on the arrival of the water cart. Every Sunday the tanks were emptied and washed out thoroughly with a hose. In tank No. 1, where the boiling was done, there was a great deal of mud precipitated during the boiling of the water. There was no mud in remaining tanks. At this date (May 20, 1892), with forty-one barrels, one water cart, and with two men, the service was efficient.

Although we had been boiling the water for the use of the men on the grounds, and so far as in our power

had made it convenient for them to use it, it was with more or less difficulty that the employees were prevented from using hydrant or surface water. We did not at this time consider the untreated lake water safe, and notices were distributed prohibiting the use of water from hydrants and lagoons.

In April, 1893, before the opening of the Fair, the number of barrels in use amounted to about three hundred. It was not intended to carry the use of this sterilized water into the period of the Fair, the filtered water and the Waukesha water (spring water) being intended to serve the general public, but as the number of visitors increased in July and August it was found necessary to revert to the system in order to furnish an adequate supply. Later, the number of barrels was greatly reduced. Consequently, the sterilizing plant, which had been torn down upon the removal of the temporary power plant immediately before May 1, was re-erected in connection with the boiler plant in Machinery Hall, and this service reinstated. City water was used in the barrels previous to the re-erection of the sterilizing plant. August 3, sterilized water was again furnished, and its use continued to the end of the Fair. On certain other occasions, owing to changes in the temporary power plant, it was necessary for several days at a time to discontinue the use of sterilized water, and the barrels were filled directly from the city main. An excess of gastro-intestinal disorders was observed by this Bureau, and the Department of Water Supply, Sewerage and Fire Protection was at once notified. The sterilization of the water was of great importance, and the bacteriologic reports furnished by Mr. Allen Hazen, chemist, proved that it compared most favorably with any water in use during the Exposition.

The Waukesha Hygeia Mineral Spring Company obtained a concession for the exclusive privilege of piping water a distance of one hundred and one and a half miles and delivering it from the Springs in Southern Wisconsin, on the grounds of the Exposition, and there retailing the same from numerous booths at a cent a glass, and also furnishing it to customers at a price not to exceed five cents a gallon. This water was passed through a cooling plant sufficient to reduce its temperature. The machinery had a capacity for reducing 60,000 gallons of water from the ordinary temperature to 40 degrees Fah. in sixteen hours. There were at one time during the summer 167 drinking booths in and outside of the buildings, and 372 private taps for wholesale delivery.

In addition to the sterilized water above referred to, free filtered drinking water was furnished at available points by means of a hundred Pasteur filters, the capacity of each being about two hundred gallons. Four faucets and four cups were furnished each filter. No attempt was made to cool this water, but its quantity and quality, as shown by the bacteriologic examinations by Mr. Hazen, were very satisfactory.

Every endeavor was made to force concessionists, State officials and restaurant people on the grounds to filter all water used for drinking. This was in a measure successful. Filters of many kinds were used by these parties, some of them probably without much benefit. This order did not apply to the Waukesha Mineral Spring Company's supply, piped from Waukesha, Wis.

So much for the efforts of the Exposition Company to furnish innocuous water to its visitors. The

report of Mr. MacHarg, the Engineer of Water Supply, etc., will furnish additional details.

#### SEWERAGE.

The sewerage system of the city of Chicago did not extend into Jackson Park. For the care of the excreta during the construction of buildings, wooden privies with concrete floors were provided, each privy containing thirteen seats, with stalls and galvanized iron pails for solids, and troughs and sumps for fluids, and with a separate urinal trough just above the pails, and also a general urinal trough of galvanized iron along the wall facing the stalls.

An attendant threw into the pails from time to time, as became necessary, dry earth pulverized at the temporary power plant, for the absorption of dampness and the prevention of odor. A solution of copperas was from time to time freely applied to the troughs which led to the sumps, and to all the parts of the privy exposed to contamination.

A tank cart made the rounds at night, and the catch basins were pumped out and washed with copperas and the urinals carted to the nearest city sewer and dumped. The solids were conveyed to the southern portion of the grounds and dug into black earth. This proved most satisfactory except on one or two occasions of very wet weather in the spring of 1892.

Avoiding any system of contract scavenging, the Department of Water Supply, Sewerage and Fire Protection detailed its own men for the care of the privies and the disposal of the excreta. In this way the results of the system proved most satisfactory. This system was continued until the completion of the general system of sewerage and plumbing, which was shortly before the opening of the Exposition. The system last referred to, namely, for the use of the Exposition, was as follows:

All roof water was discharged directly into the lagoons or Lake Michigan, as was most convenient, through pipe sewers ordinarily, brick sewers being required in one or two cases only.

All surface water from walks, whether resulting from rain or from washing, was discharged through a system of vitrified sewer pipes to wells conveniently and economically located, and thence pumped directly to Lake Michigan. This water, while not seriously contaminated, was thought to contain sufficient organic matter to make its discharge into the lagoons undesirable. The sewage proper; that is, the discharge from water closets, lavatories, café kitchens, etc., was pumped by means of fifty-two Shone ejectors through cast-iron force mains and discharged into tanks at the cleansing works, which were located in the southeastern portion of the grounds. Here sewage was treated with chemicals. Most of the suspended matter and a large part of the organic matter in solution were precipitated, and a clear effluent water, from which all highly putrescible matter had been removed, was discharged into the lake. The precipitant commonly called "sludge" was forced into filter presses and pressed into the form of cakes, which were afterwards burned at the crematory in the extreme southeastern portion of the grounds. These cakes came out very hard, having been deprived of about 50 per cent. of the water by pressure.

Garbage and ashes were handled in the following manner: The former was placed in galvanized cans placed outside of the buildings at 11 o'clock each

## WORLD'S COLUMBIAN EXPOSITION MEDICAL BUREAU. SUMMARY OF WORK DONE AT EMERGENCY HOSPITAL DURING THE CONSTRUCTION AND EXPOSITION PERIODS.—CONSTRUCTION 1893.

night, and taken up by the Transportation Department, Mr. W. H. Holcomb, General Manager, and deposited at the crematory.

The ashes and garbage were kept separate. Ashes were utilized for "filling" on the grounds. The quantity was not great, as almost all of the cooking was done by gas.

Inasmuch as a constant fire existed at the crematory, the garbage was disposed of as soon as received. It created no nuisance whatever, and the raw material was very quickly reduced. The crematory was operated by oil as a fuel, and its practicability and efficiency were fully demonstrated.

Creolin-Pearson, in strength of one ounce to a gallon of water, was liberally used to disinfect stables, water closets, urinals, different portions of the grounds and buildings, and proved to be very efficient. Tin hand sprinklers were found convenient for its distribution.

After the opening of the Fair it was found necessary to erect a few free urinals. These were composed essentially of small wooden buildings with concrete floors and with four slate stalls emptying through a trap directly into the sewer. They operated satisfactorily.

The whole system of sewerage was constructed and operated by Mr. W. S. MacHarg, Engineer of Water Supply, Sewerage and Fire Protection.

## SANITARY INSPECTION.

Previous to the opening of the Exposition, the inspection of grounds and buildings was very satisfactorily performed by the attending physicians. The grounds were divided into sanitary districts in order the better to systematize the work. The physicians furnished weekly reports of the condition of their districts, covering privies and closets, water supply and drainage, the condition of grounds, buildings and of population.

Finally, the hospital work increased to such a degree as to necessitate special appointments for the performance of this function.

Inspection of grounds and buildings went on daily, and each Inspector furnished a report to the Medical Director every evening, covering the buildings and localities visited, sanitary condition of the same, with remarks and recommendations. From the reports of the Sanitary Inspectors the Medical Director furnished each day to the Director of Works a condensed report.

## EXPENSES.

	Cr.	Dr.
Expense of Bureau to Dec. 31, 1893. . . . .		\$44,277.17
Expense of Bureau from Jan. 1 to March 31, 1894. . . . .		638.79

## DEDICATION.

For the exigencies of the dedicatory services on the grounds Friday, Oct. 21, 1892, and of the dedication of certain State Buildings October 22, the following organization was effected:

1. The employment of four nurses and one head nurse, an extra male orderly and a female orderly for the emergency hospital.

2. The establishment of a substation (No. 1) in the north end of the Manufactures Building (west side), divided into three rooms, one bed and a rattan lounge in each of two of these, the reception room being in the center, in charge of Dr. W. H. Allport and Dr. Bertha Van Housen, with two trained nurses and one male orderly. Another substation (No. 2), like No. 1, in charge of Dr. E. T. Edgerly and Dr. Jennie Hayner, was located in the south end of the building, east side. These were otherwise equipped for meeting such emergencies as arose. They were numbered 1 and 2, and also distinguished by the flag of the Medical Bureau. A patrol wagon inside of the Manufactures Building was at the disposal of the medical officers in charge upon application to the guard in attendance, and one of our ambulances was stationed at a convenient point.

3. Four janitors were detailed to take charge of as

many wheeled chairs, designated by a red cross on white background, stationed where they would be most promptly available. Instructions were given to bring the patient to the substations by the shortest available routes. As rarely as possible the ambulance and patrol wagon were called into service for conveying patients from the substations to the hospital. Temporary provision was made for the ambulance service. Dr. G. Paul Marquis, one of the attending physicians, was detailed to accompany the ambulance and to direct and to have charge of the ambulance corps.

4. The southeast and southwest wards in the hospital were equipped, and the Medical Director's office, located between these two rooms, was furnished for the occasion.

5. Telephones were placed in the substations.

6. Certain guards were instructed to coöperate with the medical staff to preserve order, to keep clear space for the cases of accident and illness, to allow free ingress and egress of the medical officers wearing the badge of the Medical Bureau, the ambulance, the nurses in uniform and to facilitate the transfer of patients on wheel chairs or on foot to the substations.

7. Orders were issued to secure as direct a route for the ambulance from the substations to the emergency hospital as the circumstances of the occasion would permit.

8. At the expiration of the service it was the duty of the medical officers in charge of the substations to see that the whole medical outfit was immediately removed to the emergency hospital by one of the patrol wagons or the ambulance.

\* (4 premature.)

The following notice to visitors was distributed over the grounds and buildings:

WORLD'S COLUMBIAN EXPOSITION—MEDICAL BUREAU.

NOTICE TO VISITORS.

The following stations have been established within the grounds of the World's Columbian Exposition for the gratuitous treatment of those taken sick or injured during the dedication services of Oct. 21 and 22, 1892.

*Emergency Hospital.*—At the southeast corner of the Service Building, near the Sixty-second Street gate.

*Substation 1.*—At the northwest corner of the Manufactures and Liberal Arts Building, facing west toward the Wooded Island.

*Substation 2.*—At the southeast end of the same building, east of the Music Stand and facing the Lake.

These stations will be open continuously on October 21 and 22, and will display the Geneva cross. All employees of the Medical Bureau will display the same emblem.

Invalid chairs belonging to this Bureau and bearing the Geneva cross will be found in the side aisles of the Manufactures and Liberal Arts Building. An attendant will be in charge of each chair and will convey patients to substations 1 and 2.

A chair will also be stationed at the landing stairs on the west bank of the lagoon, east of the Transportation Building.

The Columbian Guards will furnish information as to the location of the stations of the Medical Bureau.

(Signed.) JOHN E. OWENS, Medical Director.

KINETIC THERAPEUTICS IN GYNECOLOGY  
OR THURE BRANDT'S SYSTEM.

BY SOFIE A. NORDHOFF, M.D.

WASHINGTON, D. C.

LATE VOLONTAERARTZ OF THE ROYAL UNIVERSITY HOSPITAL FOR WOMEN, MUNICH (BAVARIA); LATE ASSISTANT OF THE OUT-DOOR DEPARTMENT OF THE HÔPITAL BAUDELLOCQUE, PARIS.

During my recent trip to Europe, I became greatly interested in a method of treatment in gynecology which, it has been demonstrated to me, is peculiarly adapted to a certain class of cases not so readily amenable to treatment by other means. This method is known to most practitioners under the name of Brandt's method or pelvic massage, a term which is not employed by the disciples of Brandt. The Germans call it Thure Brandt's system in gynecology, mechano-therapie—or Mannelle Behandlung—while the French school prefers the name, *kinésithérapie gynécologique* or kinetic therapeutics. It has the warmest advocates among great gynecologists such as Schauta, of Vienna; Schultze, of Jena; Freund, of Strassburg; Profanter, Prochownik, Ziegenspeck, and many other eminent specialists.

It might be interesting to consider for a moment the life of this layman, Thure Brandt, who for so long a time was bitterly opposed by the medical profession, but before whom the faculty now bows in grateful recognition of his valuable services to medicine. Thure Brandt received an education as a gymnast at the Royal Gymnastic Institute of Stockholm, where he was graduated in 1842. He remained several years in this Institute in the capacity of assistant teacher of gymnastics, and became proficient in treating various diseases by Swedish movements. In 1847, that is, five years after graduation, while a sergeant in the army, a soldier was brought to him with a complete prolapse of the rectum. There being no physician in the place, Brandt, in his endeavor to relieve the patient, employed quite an original plan of treatment and meeting with success, this became the nucleus of the present method of kinetic therapeutics.

He placed the soldier in the lithotomy position, with the pelvis somewhat raised, and by vibratory

movements and gentle upward traction upon the sigmoid flexure he succeeded in returning the bowel into the normal position. Having met with such marked success in this case, his attention was directed to a number of women whom he had previously treated at the Institute by Swedish movements, and he reasoned that prolapsed uteri or displaced organs might be restored to their normal position by this same method. He now made a careful study of anatomy and particularly of the female pelvic viscera, but it was not until the year 1861, that is fourteen years later, that a woman with a prolapsed uterus consulted him. The diagnosis of this case was not difficult. For twenty-seven years she had suffered from prolapsus and for the last three years had been obliged to carry her uterus in a bag, outside of the vagina. Fourteen days of daily treatment restored the uterus to its normal position and, what is more, it stayed there until she died, that is for twenty-three years.

The news of this almost miraculous cure spread rapidly and soon Brandt had over one hundred patients daily, most of them cases that had been given up as incurable by gynecologists. He worked daily, from morning till night and became an expert diagnostician. He loosened displaced and adherent uteri; pelvic exudates disappeared under his hands; ovaries that had been imbedded in pelvic masses were freed; enlarged tubes were reduced to their normal size. To this pelvic massage he joined the Swedish movements originated by Professor Ling and having, as he thought, well systematized his treatment, he published a brochure in 1864. Most of the Scandinavian physicians considered Brandt as a quack, and either refused to read a pamphlet on a new treatment in gynecology by a layman, or after reading it had no faith in the wonderful cures reported.

Following the advice of friends Brandt published, four years later, another brochure and this time in French. The translation was very imperfect; the medical terms chosen were those of the sixteenth century; a number of certificates of complete cure, given by the patients themselves, were added; all this would have been sufficient to condemn his work, but *an comble du ridicule*, he put his military honors on the title page. A Major of the Swedish Army, Chevalier of the *Ordre de l'Épée*, captain in the infantry regiment of Skaraborg, inventor of a new treatment in gynecology! Not recognized in his own country, and ridiculed in others he ceased his publications but continued in his practice and in the elaboration of his method.

In 1872 Dr. Sköldberg, of Stockholm, who was very much impressed with some remarkable cures he had witnessed, urged Brandt to settle in Stockholm and promised to assist in giving his method the sanction and publicity which it so well deserved. Sköldberg was professor of gynecology, and after having delivered to the students a lecture on Brandt's system, and having made preparations for practical demonstration, he died suddenly and left Brandt more alone than ever.

After every means of becoming reconciled with the scientific circles had failed, Brandt withdrew from publicity, determined henceforth to do all the good he could in relieving women of their suffering, and resigned that his method should die with him. His work remained obscure until 1885—he had now

reached the age of 67, when by a sudden turn of good luck his method became recognized. The way it happened was thus:

A rich Swedish merchant whose wife and daughter had been cured by Brandt of serious uterine disease, was anxious to have the treatment known outside of its limited circle. While stopping in Vienna he tried to interest in it a young and promising physician, Dr. Profanter, and induced him to visit Stockholm in order to see Brandt and study his method. At first a skeptic, he soon was converted into an enthusiastic believer and published several articles in favor of Brandt's method. The result was, that Germany's curiosity became aroused. The following year 1886, Brandt received an invitation (to come) to Jena in order to demonstrate his method in Schultze's clinic on sixteen well selected cases. A number of German gynecologists were present and all were much impressed by the skillful manner in which Brandt arrived at his diagnoses, which were perfectly correct although he examined without the help of an anesthetic, which can not be said of the specialists. The cases were then submitted to his treatment and a strict record kept. Schultze made some drawings of the worst cases in order to facilitate comparison; one of the assistants who did not look favorably upon this novelty persecuted the patients, thermometer in hand, thinking that sooner or later he would find a rise in temperature especially in the subacute exudates. These sixteen cases were published by Schultze in February, 1887, and he remarks that this new treatment is most valuable in affections of the female pelvis, and that he firmly believes that it is most efficacious in loosening old, chronic parametric adhesions and returning the uterus into its normal position.

Shortly after the publication of this article, seventy physicians not only from all parts of Germany, but also from Austria, Switzerland, Italy and England went up to Stockholm to become pupils of Thure Brandt, and soon after the gynecologic literature was overflowing with articles on this new treatment.

Most writers after eulogizing the remarkable results witnessed, make the assertion that practical demonstration alone can teach a method so full of complicated manipulations—that it can not be learned from books, no matter how elaborate the explanations be; and then immediately they proceed to give a more or less condensed description of the technique. I will not be guilty of the same inconsistency, and refer those who are interested in this treatment to Thure Brandt's book, "*Behandlung Weiblicher Geschlecht Krankheiten*," a work carefully supervised by Professor Schauta, of Vienna, or to Ziegenspeck's brochure, "*Über Thure Brandt's Verfahren der Behandlung von Frauenleiden*," published in the *Sammlung Klinischer Vorträge*, No. 353-354, Leipzig, 1890, or to a small work in French by my friend and instructor, M. Stapfer, late Chief of the Gynecological and Obstetrical Clinic of the Faculty of Paris, who was commissioned by the Minister of Public Instruction to study this new treatment under Thure Brandt and whose work is the report of this mission, read on his return from Sweden before the Académie de Médecine, session July 26, 1892.

Mr. Stapfer is one of Thure Brandt's greatest admirers, and has given up all other practice in order to devote his whole time to kinesitherapy a name which he coined. He is in charge of the outdoor de-

partment of the Baudelocque Hospital, and I was fortunate enough to receive an appointment as his assistant and was enabled to work under his instruction and supervision.

*What is meant by Kinetic Therapeutics?*—It is the art of healing functional disturbances and organic diseases of women, by acting upon the genital organs and their circulation, by direct and indirect movements. The object is to bring about a healthier state of the circulation, lymphatic and sanguineous; to set free the various structures of the genital tract; to reestablish their anatomic and physiologic integrity—without cutting operations, without any surgical appliances, without medication, by manual skill alone.

*What are the indications for Kinetic Therapeutics?*—All functional disturbances such as amenorrhea, dysmenorrhea, menorrhagia, displacements of the uterus and its adnexæ with or without adhesions; perior parametric exudates of sanguineous or lymphatic origin; chronic and subacute inflammation of the uterine parenchyma with its consequences—leucorrhea, hemorrhages, fungosities, ulcerations, oöphoritis, salpingitis—in short, nearly all the gynecologic miseries that fall to the lot of womankind.

*What are the contra-indications?*—Acute inflammation. Pus from any cause. Malignant neoplasms; the two latter points have to be taken in their broadest meaning—including syphilis, gonorrhea, tuberculosis, actinomycosis, diphtheria, etc., cancer and sarcoma.

*Treatment.*—The rules of treatment as observed at the Baudelocque Hospital are, daily treatment,—any prolonged interruption is considered objectionable. The menstrual function does not only *not* interfere, but is considered the best time to work for loosening adhesions. Rectum and bladder must be empty. The patients are assembled in a very large room which serves as waiting and treatment room both; the advantage of this is obvious, and while awaiting their turn they watch the physicians going through the different movements with the other patients, thus having an object lesson which alone serves to teach the sometimes very complicated movements which precede and follow, and thus form part of each treatment. Several couches are in the center of the room and M. Stapfer and his assistants hard at work. The treatment couches are fourteen inches high; the patient lies with her thorax slightly raised, her knees drawn up; the operator sits to the left on a stool on a level with the couch; his left index finger in the vagina or rectum as is usually done in virgins and the right hand on the abdomen. The outer hand does all the work while the left index finger does not move but only acts as a support. The duration of treatment is from ten to fifteen minutes, except in cases of chronic exudates, half an hour to forty minutes.

Strict antiseptic precautions are taken. The hands are disinfected with solutions of bichlorid of biniodid, the latter being more in vogue in the Baudelocque Hospital. Glycerin is always added to these solutions. To anoint the index finger it is not simply dipped into some oily substance, but the right index rubs it thoroughly into the left and far above the metacarpo-phalangeal joint.

The treatment proper consists of three different kinds of movements; vibrations, circular friction and rectal effleurage or stroking. Analgesic treat-

ment always precedes the other, as a diagnosis can only be made when the tenderness has disappeared. This usually is the case after three to five days.

Chronic constipation, this never-failing symptom of retrodeviations is cured in a few days.

The gymnastic exercises originated by Ling and taken up by Brandt as part of the treatment are divided into three classes:

1. Those which deplete the pelvis.
2. Those which increase the afflux of blood.
3. Those which strengthen the muscles of the pelvic floor.

Time is too short to go into the details of the technique, and it would be a hopeless task to attempt giving a clear idea of it without illustrations or practical demonstration. Brandt does not consider his treatment complete without these Swedish movements. The Germans, in trying to improve upon Brandt's method, have done away with the gymnastic exercises on the ground that they take up too much time. The French school advocates them most highly and considers the movements a most valuable adjuvant, never to be omitted; in fact, a great many cases, especially those of amenorrhea and menorrhagia are treated and cured by exercises alone and without pelvic massage. M. Stapfer asserts that the Germans make a great mistake in discarding these muscular exercises, and he made this the subject of a paper read before the International Medical Congress at Rome, April, 1894.

Kinetic therapeutics, on account of the wonderful results obtained, would run a great risk of becoming the prey of quacks and advertising industrial gynecologists, were it not for the fact that a thorough knowledge of the anatomy of the pelvis is required. It is based upon truly scientific principles and herein lies its safeguard. Practiced by unskilled hands it may do a great deal of harm and may even prove fatal in cases of pyosalpinx. It is not sufficient to possess a good general knowledge of the female pelvis, its large nerve trunks and blood vessels, but a thorough study of the lymphatic circulation and of the sympathetic nervous system becomes a necessity. In dealing with an exudate, the operator endeavors to stimulate the lymphatics and promote absorption by working in the direction of the lymph channels. It has to be borne in mind that the lymphatics of the uterus, tubes and ovaries are directed outward, following the course of the utero-ovarian arteries and terminate in the lumbar glands. Should the exudate be near the cervix it has to be remembered that these lymphatics take the direction of the uterine artery and end in the pelvic glands.

The researches of Glax and Klemensiewicz have shown that in the center of an inflamed area, in consequence of the increased transudation, the lymph spaces become overfilled and the outflow is deficient, owing to the compression of the vasa efferentia. The operator therefore has to begin by making room in the lymphatics and by working at the periphery and gradually advancing toward the center, and as soon as the lymph stream begins to circulate he works in the opposite direction, that is, from the center to the periphery, following the direction of the lymphatics. Experiments of Lassar and Mosengeil have proved to the fullest satisfaction that kinetic therapeutics increases the rapidity of the lymph stream.

Lassar (in *Virchow's Archiv.*, vol. LXIX, p. 153). This experimenter by chemic and thermal irritation

produced an inflammation in the paw of a dog, and then introduced a canula into the peripheral end of a severed lymphatic and a few drops of lymph flowed out slowly. But as soon as massage was practiced the lymph was seen to spurt out.

Mosengeil's classical experiment described in the *Arch. f. Klin. Chir.*, vol. xix, p. 428, shows conclusively the value of massage. He injected animal charcoal into the joints of rabbits and considerable swelling took place. One joint thus treated was submitted to massage; the other was left alone. In the first one the swelling disappeared; the latter remained enlarged. On autopsy the swollen joint revealed the black substance still *in situ*, while the massed articulation was free from it. This experiment not only proves the usefulness of kinetic therapeutics, but shows the danger of such a method applied where the quality of the exudate is of an infectious nature.

The nerve supply of the lymphatics is derived from the sympathetic nervous system. This latter is of the utmost importance to the kinetic therapist. I could not help wondering how little is said in the standard text-books of gynecology on the rôle played by the sympathetic nervous system; in fact most of the books on anatomy treat this system with marked indifference. In my opinion kinetic therapeutics is directed chiefly to the lymphatic and sympathetic systems and it is to be hoped that its practice will cause some study in this rather unexplored field, and throw some light on the oftentimes obscure pathology and symptomatology of uterine disease. If we take a case of analgesic treatment we will soon find that we come across certain spots that are particularly painful and in making a careful study of the anatomic relations we can always trace these "points douloureux" to sympathetic ganglia. There is for instance, at the junction of the uterus and Douglas' fold, to the right and left of the posterior vault of the vagina, a most tender point, which when slightly touched makes the patient wince and here we find the uterine ganglia. Occasionally the sacral nerves can be traced back to their foramina at the level of which four sacral ganglia are found, which are united to each other and send numerous branches to the hypogastric plexus. This whole region is in certain affections highly sensitive and causes the intense reflex symptoms so often noticed in uterine disease.

The sympathetic nervous system holds a place far more important than is usually attributed to it, and even a superficial glance at the anatomy of the pelvis will reveal the fact that the pelvic viscera derive their mean nerve supply from the sympathetic system. At times this nervous system becomes one of the most powerful factors in the human anatomy, namely in causing the expulsion of the fetus at term. Obstetricians consider the center of parturition to be situated in the medulla oblongata. How does the impulse reach the uterus? Partly by way of the spinal cord through the sacral nerves, partly through central filaments of the sympathetic nervous system, attaining its maximum of intensity in the plexus uterinus magnus, situated at the level of the bifurcation of the aorta. Four centimeters below, this plexus divides into the two hypogastries, and these, together with numerous branches from the lower lumbar and superior sacral ganglia, form two divisions; the smaller one supplying and surrounding the rectum, and the larger one, after uniting with the

sacral nerves, forms the cervical ganglion, which supplies the whole uterus and especially the cervix.

Now let us travel backward this same road, and many of the obscure reflex symptoms can be explained. If we have to deal with chronic exudates, with the unavoidable pressure effects upon the nervous tissue in the pelvis, the impulse will travel upward to the medulla and on its way produce the various reflex symptoms which are called by Freund cerebro-spinal. We will observe bearing down pains, sensation of fullness in the pelvis, backache, colicky pains, chronic constipation, nervous dyspepsia, vomiting, asthma, pain in the cardiac region, palpitation, globus hystericus, migraine, amblyopia, cataleptic and even epileptic attacks.

Kinetic therapeutics is a valuable auxiliary in curing displacements of the uterus. When might we speak of an organ as being displaced, whose ligaments permit movement in every direction so that there is no one normal position a departure from which would constitute a pathologic displacement? Physiologic displacement is an essential feature of a normal uterus and as soon as it is in the least interfered with we know that something is wrong. No subject in anatomy has perhaps caused such wide differences of opinion as the so-called normal position of the uterus. Great anatomists as Luschka, Braune, Cruveilhier and Henle consider it normal with the fundus in the hollow of the sacrum and according to Schultze, the long axis of the uterus is nearly parallel to the horizon. More recent investigators speak of a normal ante flexion, but who can guarantee that they are right? Post-mortem we see healthy uteri nearly always in retroversion and during life the gynecologist does not often encounter a healthy organ.

We know to-day that deviation of the uterus in itself does not call for treatment, and every gynecologist has seen cases of marked displacement without a single symptom. Some authors have gone so far as to deny that any pathogenic importance whatever attaches to simple displacements without adhesions. It is certain that adhesions give at once a different aspect to the deviation and according to the degree of mobility destroyed we have to deal with the different reflex symptoms, from the multiple neuralgia to chorea (Schröder) and hystero-epilepsy (Sielski). It is the province of kinetic therapeutics to remove the cause of displacements.

Exudates are treated as described above.

Adhesions of parametric origin are disintegrated and worked back into the circulation.

Shortened ligaments are stretched and return to their normal length in a remarkably short time. If the shortening be of a peritoneal nature the operator must be satisfied if adhesions are separated and the uterus regains a relative degree of mobility; the peritoneum if once contracted does not regain its normal elasticity. When we come to treat relaxed ligaments we encounter more difficulty and we have to take into consideration that they consist merely of connective tissue and scanty muscular fibers. These latter not being sufficiently numerous to restore the elasticity of the ligaments. Some enthusiasts of Brandt's method claim to have shortened these supports. The only way in which I could account for their success, which does not otherwise coincide with physiologic laws would be that by mechanical irritation they have produced an inflammation which

naturally resulted in contraction of the ligaments.

I will say one word on the treatment of chronic constipation, although it does not, strictly speaking, belong to pelvic massage. It is perhaps one of the most valuable presents we have received from the hands of Thure Brandt. I have seen cases of habitual constipation where three cathartic pills, together with 3 ss. ol. ric. and an enema were the daily order of things, and such cases have been cured in a few days only by kinetic therapeutics.

The reason of these remarkable results is easily understood. Once more the sympathetic nervous system has to be brought into the foreground. We all know that the physiologic activity of the alimentary canal depends on the proper innervation and circulation. Virchow has shown that in innervation disturbances, in consequence of which the muscular fibers of blood vessels lose their energy and the elastic fibers become relaxed, thus interfering with the physiologic function of the intestine, kinetic treatment is eminently satisfactory in strengthening the muscles of the abdomen, producing peristalsis and in the mechanical removal of skybala from the colon. Another most favorable result is the beneficial effect by reflex action upon the stomach.

Subinvolution of the uterus is cured by this method in so short a time that one can but wonder at it. It is not rare to see cases of enormously enlarged uteri reduced to their normal size in a few days.

Cases of metritis and endometritis respond to treatment in a relatively short time; but should the latter be due to fungosities, curetting would be the more rational treatment.

It is remarkable how quickly all the subjective symptoms disappear even in the most severe cases, while the objective symptoms remain behind, to serve as a guide for the continuation of the treatment, long after the patients consider themselves cured. Kinetic therapeutics is no longer considered a novelty, but holds a high place in the estimation of the leading gynecologists. The most prominent specialists abroad have given it a fair trial and acknowledge that not only did the treatment fully come up to their expectation, but that it rendered unnecessary in many instances surgical interference, particularly such operations as Battey's. If kinetic therapeutics had done nothing more than to give the death blow to Battey's operation this fact alone would suffice to give this method a foremost rank in gynecology.

Alexander's operation for shortening the round ligaments, with its modifications by Adams and Alquié has a dangerous rival in kinetic therapeutics. Most of the disciples of Thure Brandt are of the opinion that ventro-fixation has had its day and will be substituted by the more rational kinetic therapeutics. Ventro-fixation as recommended by Koeberlé, Olshausen, Lawson Tait, Kelley, Sänger and Leopold is at its best a dangerous operation and by no means justified by its results. Laparotomy, the forcible breaking loose of adhesions and stitching of the uterus to the abdominal parietes is a serious undertaking, especially if we think that after all it is only the substitution of an anterior for a posterior fixation and oftentimes a double fixation. The dusting of aristol, dermatol or iodoform over the loosened adhesions, or the application of sterilized gauze, or even gold leaf, has proved inadequate.

The cure of prolapsus uteri is, although wonderful in the hands of Brandt, not universally successful if undertaken by his followers, and Winckel made the statement that colporrhaphy will, together with Brandt's system, be in the future the treatment for such indications. It will easily be seen that where the pelvic floor gives no support whatever, Brandt's treatment alone can not hold the uterus up. In these cases the levator muscle is found to be severed and operations such as devised by Freund, Martin and Winckel will be found beneficial, as they bring about a union of the muscular fibers of the levator and the vaginal wall. Brandt's per cent. of cure of prolapsus is between 70 to 80 per cent. and it is doubtful whether surgical operators have the same good result. There are cases on record where five and more operations did not prevent the descent of the organ and Le Fort's operation for complete closure of the vagina had to be resorted to.

After having taken up so much time in trying to bring out the advantages of kinetic therapeutics, I have to point out its disadvantages. All that can be said against it, even, by Brandt's adversaries, is its troublesomeness, the difficulty of becoming familiar with it—a trip to Sweden or Germany to study with one of Brandt's disciples being indispensable—and last, not least, the long duration of the treatment extending in chronic cases over several months.

Brandt teaches no longer, having arrived at the venerable age of 77 years. Gynecologists from all parts of the civilized world are constantly applying for the privilege of studying under his direction; but within the last year or two he has felt it to be incumbent upon him to transfer the duties of teaching his method to his disciples. After many years of bitter disappointment, harsh criticism and antagonism he now has the satisfaction of seeing his labors appreciated, his method adopted by the scientific world and of having his name handed down to history as one of the great philanthropists of his day.

## SUPRA-PUBIC CYSTOTOMY FOR CALCULUS IN THE BLADDER.

TRENDELENBURG'S TRANSVERSE INCISION—TRANSVERSE DIVISION OF THE RECTI AND PYRAMIDALIS MUSCLES—INCISION OF THE BLADDER WITHOUT INFLATION OF THE RECTUM OR INJECTION OF THE BLADDER.

Read before the St. Louis Medical Society, Dec. 22, 1894.

BY A. H. MEISENBACH, M.D.

PROFESSOR OF SURGERY IN THE MARION-SIMS COLLEGE OF MEDICINE.  
ST. LOUIS, MO.

The object of this short paper is to bring to your notice an operation, which though described in several works on surgery in the German<sup>1</sup> is not mentioned (so far as I have been able to investigate) in any English or American text-book on surgery, with the exception of the English translation of Kocher's "Operative Surgery" recently published. I do not believe that the technique of this operation as practiced by Trendelenburg, Tillman, Kocher and other

Continental surgeons is generally known or practiced in this country. The operation I have reference to is the operation of supra-pubic cystotomy, by a transverse incision through the skin and abdominal muscles, without previous inflation of the rectum or injection of the bladder. This operation is known as Trendelenburg's method of supra-pubic cystotomy (*sectio alta*) by means of the transverse incision.

This method was first suggested by Günther and carried out afterward by Bruns-Lotzbeck. To Trendelenburg, is due the credit of bringing the operation to general notice in Germany, and perfecting the technique, such as is now practiced by himself, Tillman, Kocher and others. The technique of this operation renders it unnecessary that the rectum and bladder be previously distended, which in the *sectio alta* by means of the median vertical incision is of importance, especially the injection with fluids or air of the bladder. The majority of surgeons have now discarded the inflation of the rectum, but still use some method of distending the bladder, either by fluids or air.

As you are all aware, the object in inflating the rectum or distending the bladder, is to bring the viscus out from behind the pubes, thus rendering it more accessible especially in the adult; also to increase the dimensions of the pre-vesical space by pushing up the peritoneum. It is well known through experience, that inflation of the rectum is at the best unsatisfactory, and has therefore been practically discarded. That distension of the bladder is not always without danger, is also well known; especially in persons of advanced years in whom the bladder walls are friable.

It is true that the Trendelenburg position (elevation of the pelvis), increases the dimensions of the pre-vesical space, but the median vertical incision in this position (with distension of the bladder) does not give as free access to the organ as the transverse incision. This is due to the form of the wound as produced by the median vertical incision. This wound is elliptical when pulled asunder by retractors, with the points of the ellipse at the pubes, and toward the umbilicus, so that the narrowest point of the wound is at the pubes just where the greatest amount of space is wanted for free manipulation of the deeper parts. In the transverse incision the wound is triangular or lozenge shaped, with the base or widest part right at the pubes.

#### TECHNIQUE.

The patient is carefully prepared; pubes shaved, bowels emptied thoroughly. He is then placed in the Trendelenburg position, the pelvis as high as necessary, so as to allow the abdominal organs to gravitate toward the diaphragm. The incision through the skin is transverse over the upper margin of the pubes, in a slightly curved form, convexity of cut over the pubic bone; it is best to carry the convexity of the incision about one and one-half centimeters onto the pubes; by doing this the insertion of the recti can be more easily severed, very close to the bone. The length of the incision extends from over the region of one inguinal canal to the other on the opposite side. The cut is carried through skin and superficial fascia, exposing the pubes and the insertion of the recti muscles. Two Volkmann hooks or retractors are now placed in the skin wound, one

pulling upward toward the penis, and the other downward toward the umbilicus. A few veins may need ligation. A catheter or sound of full curve is now introduced into the bladder and controlled by an assistant, or it may have been introduced before the skin incision is made. The skin wound being held asunder by the retractors or hooks, the insertions of the recti muscles are fully exposed. Their insertions are cut transversely across, keeping the edge of the knife well against the upper border of the pubes. This can be facilitated by pressure of the index fingers of the left hand on the muscles, thereby putting the tendons on the stretch; in this manner both recti may be partially or wholly severed from their insertion as well as the pyramidalis muscles, as the operator may see fit.

FIG 1.—The heavy line over the pubes shows the transverse incision; dotted lines the form of the wound when held apart by retractors.

The division of the muscles brings into view the pre-vesical space. A hook or retractor is now hooked into the umbilical end of the wound (the instrument must be blunt so as to run no danger of wounding the peritoneum) and traction made downward. Two more hooks are inserted into the pubic angles of the wounds and traction made to the respective sides. This gives us a large triangular wound with the base in the most favorable position for manipulation at the pubes. At the bottom of this wound we find the pre-vesical fat, veins, the peritoneum and bladder. In the adult the lower fold of the peritoneum may dip down behind the pubes, depending on the size and disposition of the fundus of the bladder. By means of rat tooth forceps or a blunt dissector or knife-handle the fat is separated; by a little care the

veins need not be injured, and no bleeding need occur by this manner of blunt dissection. The anterior wall of the bladder is exposed and is recognized by its pinkish color. The anterior wall of the bladder should be well exposed upward and downward. If the operator works skillfully, the peritoneum may not become visible during the operation. It is well at the beginning of the separation of the fat to work well down behind the pubes, for then there is no danger of encountering the peritoneum, and we can, after the bladder wall has been exposed, readily work it upward, along with the veins and pre-vesical fat. At this stage of the work the catheter comes in for its part in the technique; the assistant who has it in charge firmly depresses the ends, thus carrying the point against the anterior wall of the bladder. It can be carried higher into the fundus, or lower, as the operator may desire, and by this means he can clearly outline the extent of the bladder.

The anterior surface of the bladder having been sufficiently exposed, the catheter lifts the wall well up into the wound at any point the operator may determine. By means of a sharp hook, or better, by means of a loop of silk passed through the muscularis, the bladder is fixed; we may, if we choose, put in two loops of silk; the one near the fundus, the other lower down.

The organ is well drawn upward and the tip of the catheter is used as a guide to cut down upon; with a sharp narrow pointed knife we cut down beside the tip of the catheter into the bladder. It is well to begin the incision into the bladder near the fundus and extend the cut downward, so that one or two fingers can be introduced into the interior of the bladder. A gush of urine usually follows the opening of the organ. The interior can now be examined by the fingers, or inspected by means of an electric light introduced into the cavity. If the operation be done for calculus, it is now extracted, or any other procedure that the particular case may require. After the operation is finished, the bladder is irrigated with a 3 per cent. boracic solution. A soft rubber T-drainage tube is now inserted into the cavity of the bladder and the other end passes out of the skin wound. Into the wound and around the tube iodoform gauze is packed. Each outer angle of the wound may be brought together by one or two sutures so as to lessen the size. A suture is passed through the skin and drainage tube, so as to retain it in its place; over this gauze and cotton.

The patient is put to bed and as soon as narcosis passes off is instructed to lie on either side, right or left, so as to admit of free drainage. The tube is left in the bladder one to two weeks. The gauze packing is removed as often as is necessary. The patient is allowed to sit in an upright position as soon as possible after three to four days.

*Case.*—On December 16, Mr. K. S., aged 70, residence Lebanon, Ill., was referred to me by Mr. H., a medical student of the Marion-Sims College. The patient for a year past had suffered from frequent urination. He had been treated by three or four physicians without relief. He was sent to me under the supposition that he was suffering from an enlarged prostate. Patient stated that his appetite was fairly good, he slept well, and did not have to get up very often to urinate, but during the daytime had to micturate very often, and that there was considerable pain immediately after urination. This pain he located over the pubes. Examination of the rectum revealed that the prostate was not enlarged, and could hardly be responsible for his symp-

toms. I introduced a sound into the bladder and it was hardly in the bladder when I came into contact with a stone located on the right side. The introduction of the sound caused him much pain, and he was attacked by a trembling spell, so that I had to desist from further investigation.

I saw him again the next day; he had a slight rise in temperature 100 degrees, and felt unwell. While holding the thermometer in his mouth he had a slight syncope. I advised an operation, and that he should go to a hospital. He agreed to operation and entered the Rebekah Hospital the following day. Urine showed slight trace of albumen.

*Operation.*—Wednesday morning, December 19, the operation of supra-pubic cystotomy was done. The patient had received two good doses of whisky; the one an hour before, the second a half hour before the operation. A hypodermic of 1-6 gr. of morphin was given along with the second dose of whisky. The whisky and morphin were given so as to avoid the necessity of giving much chloroform. The patient was placed in the Trendelenburg position on Edebohls table. A silver catheter was introduced into the bladder and held by an assistant. I had taken the precaution to arrange a stop cock on my catheter, in such a manner that the nozzle of a syringe could be attached, so that I could inject the bladder should I find any difficulty in reaching the same, it not being injected. I made a transverse incision from one inguinal canal to the other; the line of incision was slightly curved, with convexity over the pubes, and carried about one and one-half centimeters onto the pubes. The cut was curved down through skin, fat and fascia onto the recti muscles. There was no bleeding. The recti and pyramidalis were now cut through, keeping the edge of the knife on the pubes. A retractor was placed in the umbilical end of the wound, drawing downward, one also into the pubic angle of the wound, drawing to the respective sides. The pre-vesical (cavum Retzii) space was now freely exposed, especially well the parts behind the pubes; with a mouse tooth forceps and a blunt dissector I cleared away the pre-vesical fat and veins over the anterior wall of the bladder.

I had my assistant press the catheter well up against the pubes as low down as possible, with the point of the catheter as a guide. I was quite safe in my manipulation, and sure that I was below the lower fold of the peritoneum. As soon as I reached the bladder, which could be easily noted by its pink color, I cleared the fat well off from the anterior wall as far as the fundus. The peritoneum did not come into sight, was covered by fat and pushed along with it out of the way. Into the anterior wall of the bladder near the fundus, I inserted a loop of silk, passing it through the muscular coats. This loop I used to fix the bladder previous to the incision. I now had my assistant crowd the point of the catheter well against the anterior wall of the bladder near the fundus. I found that it was an easy matter in this case to penetrate the bladder wall with the catheter tip. I did this, and then used the catheter as a guide, alongside of which I inserted a narrow pointed bistoury and enlarged the wound downward so that I could introduce two fingers into the bladder. The catheter was now withdrawn. I could readily feel a large, oval, flattened calculus in the right segment of the bladder. Passing a stone forceps in alongside of my fingers, I readily seized it. I found that the bladder wound was quite small for the stone to pass through; by means of a rotary motion I pushed it out of the bladder through the wound without enlarging the same.<sup>2</sup>

The bladder was thoroughly washed out with a 3 per cent. boracic acid solution. A soft rubber T-drainage tube was inserted in the bladder, the other end passing through the skin wound. I fastened the tube into the skin wound by a single suture through skin and tube. The depth of the wound around tube was packed with iodoform gauze, the ends left in the upper part. The outer angles were closed, each by two sutures. Into the top of the protruding drainage tube, I inserted a T-tube of tin ore, over each arm of which a rubber tube was passed. The rubber tube extended over the abdomen of the patient, well over each side. The dressings were applied so as to have the ends of these tubes protrude. The patient by this arrangement can lie on either side and the urine is carried by means of these tubes into a urinal or dressing, and thus the wound is protected, in a measure at least, from the effect of the escaping urine.

The operation occupied about half an hour. I could have done it in about twenty minutes, but a

<sup>2</sup> Mulberry calculus, 1 $\frac{3}{4}$  inches long, 1 $\frac{1}{2}$  inches wide; weight 1 oz., 2 drachms.

little time was lost on account of a hitch on the part of the assistants. It can easily be accomplished in a careful manner in fifteen to twenty minutes time. The patient reacted well from the operation. Not a tablespoonful of blood was lost. Twenty-four hours after the operation the temperature was 100, which, however, in the next twenty-four hours fell to normal.

On the third day the dressings were changed and the packing removed. Tube left undisturbed. Patient is doing well; rests and has no pain; urine escapes through tubes as above described.<sup>3</sup>

*Remarks.*—The experience gained by an operation by a new method in a single case can not usually be taken as a criterion of the value of a method, unless its merit has been established by other operators. Its decided advantage over the median vertical incision was, however, clearly demonstrated and especially the ease with which the pre-vesical space is laid open, and the lessened danger of wounding the peritoneum. This is easily understood when we bear in mind that in the transverse incision, we cut parallel with the lowest fold of the peritoneum, as it is reflected over the fundus of the bladder and in a direction that is oblique to it, or in other words away from it.

In the median vertical incision the opposite obtains, as here we cut directly at right angles to the peritoneum, and directly over it in the umbilical end of the wound.

Based on the experience of others, and my own in the case reported, I would offer the following conclusions:

1. That the transverse incision is more easily executed from a technical standpoint.
2. That it affords more space in which to work in the depths of the wound than the median incision, and hence superior for any exploration of the bladder, for whatever condition.
3. That there is less liability to injury of the peritoneum, because the knife is used parallel with and on a level below its lowest fold.
4. That it is unnecessary to inflate the rectum.
5. That it is unnecessary to inject the bladder, and consequently, the risk of injury to the organ is avoided, which in the aged is an element that should always be considered.
6. That the catheter in the bladder is a safe guide to the location of the fundus and anterior wall.
7. That with the catheter as a guide, the bladder can be incised with ease and facility.

### A PUNCTURE WITH A BONE OF A LIVING FISH IN THE WEST INDIES, FOLLOWED BY LEPROSY IN A CAUCASIAN SUBJECT.<sup>1</sup>

BY ALBERT S. ASHMEAD, M.D.

LATE FOREIGN MEDICAL DIRECTOR TOKIO HOSPITAL, JAPAN.  
NEW YORK.

I have had an opportunity of examining a case of leprosy in this city, which has been first seen by a medical friend of mine, who knowing that this dis-

ease was a subject in which I had always been deeply interested since my sojourn in Japan and that I had published a number of articles about it in the medical papers, has been kind enough to let me study the case.

C. G., aged 35, but looking 50, of more than average intelligence, of intemperate habit, born in Germany, of German ancestors, came when 2½ years old from Germany to the port of New York; has been married twenty years; has five living children all healthy, one a married daughter, who has a child of 7 months. He says he was healthy until six years ago. The following is his history: He lived in New York until he was 18, when he went to Brazil, as an engineer's storekeeper; the trip occupied two months. He left there and went to Aspinwall as waiter and chief cook on a ship belonging to the Pacific Mail. He remained in this service two and one-half years when he changed to the Savannah line, as cook, and remained in that service four years. Then he was employed by the Ward line running between New York and Havana, Matanzas, Tampa, Tuxpani and Vera Cruz. He was with that line one year. He then worked six months on a steamer running to Santiago, Cuba, Nassau, Cienfuegos. He went then to the Clyde line, running between New York, Charleston and Jacksonville, where he remained one and a half years. After that he entered the service of the Red "D" line, running between New York and Curacao, Puerto Cabello and La Guayra. During all this service his family lived in New York, and his employment on his trips was always that of cook, storekeeper or waiter.

Six years ago he was on board a steamer running between Tampa, Key West and Havana, on which he had been employed during the preceding four months. Just as he was leaving Havana, from which the run to Key West is only a night's trip, while cleaning a red snapper, a fish which among sailors has the reputation of possessing a poisonous fin just behind the gills, he punctured with the bone of that fin the tip of the thumb of his right hand, through to the bone. The next morning he felt no pain in his hand, but the arm was beginning to swell; it continued to swell for some days, then the swelling subsided, the whole process lasted a week. At the climax it was about three times its natural size, the swelling extending to the shoulder. The man was under the treatment of the U. S. Marine-Hospital surgeon at Key West, and gradually recovered. Immediately afterward an eruption appeared on the front of the chest, the head and face. Watery vesicles appeared, which broke and formed huge scabs.<sup>2</sup>

Dr. Daniel M. Burgess, U. S. Marine-Hospital Inspector at Havana, treated him for this, but he did not define the case as having any relation to leprosy. When these eruptions were cured, after some months, there remained red blotches which crossed his nose and cheeks, and appeared symmetrical on his forehead over the eyebrows. Nothing appeared on the chest, where the eruption had been localized. These red blotches gradually thickened, hardened and became nodulated. He first noticed this on the sides of the nose. None of the blotches had at that time shown on his ears. This condition continued increasing; his ears became tuberculated, and six months ago Dr. Burgess of Havana, first declared the case to be one of leprosy. Soon after the first outbreak of blotches,

<sup>2</sup> A vesicular or porriginous eruption is, in China and Japan, frequently the initial lesion of leprosy.

<sup>3</sup> February 20. Wound closed. Urine passing per viam naturalem.  
<sup>1</sup> This case has not been reported before. It has been in charge of the physician who now attends it, for two years. His diagnosis of leprosy was not made until three months ago, when another physician at the Presbyterian Hospital, N. Y., discovered the leprose bacilli. The first diagnosis of leprosy, as was afterward learned, was made in Havana six months ago, by Dr. Burgess. My own diagnosis of leprosy is the third in the case.

the patient had discovered a numbness in the ulnar side of his forearms; he had no numbness in the feet until two years ago, at a time when my medical friend treated him for pleurisy and pneumonia. The hardness and hypertrophy about the wings of his nose, cheeks, eyebrows and ears was gradual; it began three years ago.

*Present Condition.*—February 17, nose hypertrophied, three times its natural size, tuberculated, nodulated; both ears hugely hypertrophied, tuberculated and pendulous; the whole forehead hypertrophied and nodulated; cheeks, upper and lower lips, fingers of both hands hypertrophied and nodulated; the back of both forearms, tuberculated. Color of skin, face, neck, hands and forearms, a deep tawny hue. The tongue can not be bent from right to left; it is bent over to the right side. He has the well-known leonine face expressive of leprosy. The patient has a feeling of stretched numbness in the ulnar side of his forearms. The toes of both feet have been numb these two or three years. Ulceration on the tips of the three larger toes of both feet. He has just returned from a trip to Venezuela, which lasted twenty-five days, and is now laid up on account of the sores on his feet. He has no history of any disease, except chagres fever, seven years ago, and of pneumonia two years ago. I saw four generations in his house; his mother apparently in good health, his married daughter and his two sons, aged 5 and 7 years, and the married daughter's infant son seven months old. The married daughter is of a strikingly pearly white complexion. Both sons present a similar complexion. The infant grandson is in robust health. There is no history of leprosy in the family in any preceding generation. I cut one of the tubers from the third finger of his left hand, and from sections made with the microtome, stained with carbol fuchsin and methylene gentian violet, found lepræ bacilli in abundance, spherical accumulations of bacilli or bacilli heaps, the so-called "leprosy cells."

Here we have, then, a man who had been exposed to the influences of leprosy countries for at least eleven years; who received a wound from a fish caught in what we may call leprosy waters; the wound is peculiar in that it was anesthetic at the start; when it healed, the consequent swelling abated; there supervened a peculiar vesical eruption, which on breaking forms huge scabs. When he recovers from this, there appears with complete evidence the erythema or the plaques of leprosy, followed by hypertrophy and nodulation, these also characteristic of leprosy. From this moment, beyond doubt, the case was manifestly leprosy, although the truth had not been recognized in the earlier stages.

Now these questions arise:

Did the patient have leprosy germs latent in his system at the time of his accident?

Was he inoculated with leprosy at that time?

If there were such latent germs, would they have remained latent had not such an accident occurred?

Is it necessary, when leprosy germs are latent in the body, that an exciting cause intervene to develop them into activity?

Is it the case in leprosy as in tuberculosis, that germs may remain latent always?

I must remark here that everything seems to show that there are fewer chances of evident inoculation of leprosy germs than of tubercular germs, and that

therefore there is greater probability of latency of leprosy than of tuberculosis.

There has always been a suspicion, for obvious reasons, that fish has something to do with leprosy, and I believe myself in intermediary marine host function. Can the case in hand be considered as corroborative of this opinion?<sup>3</sup>

Hansen himself says that leprosy if not contagious, can at least be inoculated. The patient in question is living in fond relations with four generations, in a tenement house containing twenty families, in a non-leprosy country. He is a New York man, having come here at 2½ years of age; and therefore not to be shipped home, as might a Chinaman. What is our duty to the community, to the inmates of the tenement, to the man's family, and to himself, under these conditions? If he is reported to the board of health he has only to expect the utmost rigors of charity; he will be put in a tent on some island, and condemned to perfect isolation; his family will suffer by the report.

If this patient is not reported and isolated, according to Hansen's belief, sooner or later, some member or members of his family may become inoculated. (His married daughter and his two boys have now the peculiar pallor which, in the East, is considered as premonitory of the disease.) If they do become inoculated with leper germs, or if they are already inoculated with them, and yet escape the outbreak, may we not suppose that being in a non-leprosy country, and no incident like that which originated the disease in our patient occurring, the germs will remain forever latent? My own belief as to the contagiousness or the inoculability of leprosy is that the measure of danger is in the individual, the race and place of residence. There is much more danger of leprosy here in New York from the cohabitation and breeding of a leper with a healthy woman, (a child was born to our patient's wife one year after his outbreak of leprosy) than from contact or any such relationship. The Oriental law is that a leper shall breed with his own generation of leprosy; a leper belonging, let us say, to the second generation, that is being the son of a man or woman in whom the disease first appeared, will be allowed to marry the daughter of a man or woman in whom the disease first appeared, and so for the other generations. In this way the susceptibility to leprosy becomes extinct in the fourth generation and the leper germs will always remain latent afterward in that family.

## A CASE OF GUMMA OF THE CEREBRUM.

Read before the Chicago Pathological Society, Dec. 10, 1894.

BY D. R. BROWER, M.D., AND D. D. BISHOP, M.D.

CHICAGO.

This is a case of syphiloma which is in some respects very interesting. I have no regular report of the case but will simply recite the symptoms that were present, and Dr. Bishop will show his very carefully prepared specimens.

The patient, aged 52, was brought to me by his family physician, October 23. At that time he had epileptiform attacks of the left upper extremity, the attacks beginning in the little finger and ring finger and gradually involving the hand, fore-arm and arm.

<sup>3</sup> Kaurin and Beaven Rake are of opinion that there is possibly some intermediary stage, through which the bacillus passes, or some undiscovered host in whom it undergoes a further development ere it can reproduce the disease, which has so far eluded our observation.

But when the paroxysm began in the little and ring fingers the patient could, by a strong mental effort, especially when aided by his grasping something, stop the paroxysm at that point, and it was a very uncommon thing for the attack to get beyond the muscles of the fore-arm or possibly the arm. But if he failed by this effort of the will to arrest the paroxysm, then the facial muscles and afterward the lower extremity were also involved in the movement. Consciousness was perfectly maintained during all of these convulsive seizures, except the first one, which occurred while he was in Wisconsin fishing, and he fell down then in the boat. That probably was a general movement. These attacks were very frequent, fifteen or twenty occurring in the course of the day. His arteries were very much degenerated, especially the radial. I expressed the opinion that we had a localized brain tumor or a meningitis probably in the arm center of cortex. I advised him to go to the Presbyterian Hospital for observation and later on, if necessary, an operation could be made. We immediately placed him on large doses of iodid of potassium and after three or four days the convulsive seizures disappeared. He remained here until November 5, that is about two weeks. The paroxysms had entirely stopped and I sent him home, supposing he had recovered from his illness. I advised him to

operating room, that it was an abscess and not a gummata, and the brain was explored in every possible direction for pus, but it was not found. Dr. Senn then cut into the mastoid cells expecting to find a mastoid abscess, but failed. The dura mater was thickened and adherent, as though he might have had a pachymeningitis some time previously.

This case serves to illustrate again the fact that you can not locate Jacksonian epilepsy on the external aspect of the hemisphere, always, even when you have a typical Jacksonian epileptic paroxysm, for sometimes it is due to a lesion beneath the centers, involving the centrum ovale, and again, you may have an extensive abscess in the petrous portion of the temporal bone and no cerebral abscess accompany it. The location of the tumor is such that the arm center must have been irritated first and then with the extension of the tumor paralysis came on.

Dr. Bishop will give us the results of his careful pathologic and microscopic examination.

#### NECROPSY.

Nov. 23, 1894, by Dr. D. D. Bishop. Save for the incisions over the right mastoid and right molar regions, made for operative purposes, no abnormal conditions were found in the scalp or skull.

**Dura mater:** This and its falciform process were adherent over the external and internal surfaces of the right cerebral hemisphere at the motor area.

**Brain and pia mater:** The dura removed, a growth is seen projecting into and rising above the superior longitudinal fissure, and apparently growing from the interior of the right hemisphere. Upon removal of the brain and more careful examination the following conditions were noted: The growth projects from the internal and superior surfaces of the hemisphere, pressing aside the cortical substance. The presenting surface is elliptical, the long axis corresponding with that of the cerebrum. The surface measurements are six by five c.m. Its posterior margin is one and one-half c.m. in front of the depression marked by the junction of Rolando's fissure with the superior longitudinal fissure, while its anterior margin extends well forward into the ascending frontal and superior frontal convolutions. But very little was visible upon the superior surface of the hemisphere. The inferior margin reaches externally as far as the gyrus fornicatus.

Upon section, the growth seems to spring from the centrum ovale and is about four c.m. deep. It projects into the superior and ascending frontal convolutions and gyrus fornicatus, bulging out through the collosomarginal sulcus. It is covered upon its unattached surface by the pia mater which is only slightly adherent, blending off at the borders of the growth into the surrounding pia mater of the unaffected brain. At no point does the pia seem to be in close relation to the growth as one would expect to find if the origin were in that structure. On the other hand, it springs out firmly from the centrum ovale, bulging out through the brain substance as before stated.

The pia mater over the convex free surface of the growth is thickened and its vessels engorged.

The interior shows a central area of white softening, about this a slightly yellowish zone, while the periphery is light gray in color and presents numerous distended vessels, some of which are distinctly

INNER SURFACE OF RIGHT HEMISPHERE. (GRAY).

The portion occupied by the gumma is shaded. A, ascending frontal; F1, superior frontal convolution; c, Rolando's fissure; cm, collosomarginal sulcus; Gf, gyrus fornicatus pushed downward by the growth.

continue the iodid of potassium. On November 17, twelve days after he left, his physician wrote me that there was hemiplegia of the side that had been the seat of the convulsive seizures. I at once wrote to the physician to bring him back in order that an operation might be made. He was accordingly brought back, and died four days afterward.

The seat of the tumor was not cortical, as I supposed it to be, but subcortical. It involves the paracentral lobule and extends deeply into the centrum ovale, and doubtless began there. I think there can be no doubt that it began by making pressure upon the fibers that come from the upper extremity center and gradually extended until it produced complete paralysis. The external aspect of the hemisphere is perfectly intact. When the operation was made by Dr. Senn, failing to find anything abnormal we concluded the diagnosis was wrong, and inasmuch as there was a history of an ear abscess that began fifteen or twenty years ago, with an occasional discharge, we rather jumped at the conclusion, in the

thrombosed. The mass then blends off insensibly into the deep cerebral tissue. The petrous portion of the temporal bone was necrotic and contained some inspissated pus, but there was no extension to the mastoid or other contiguous structures.

The basal vessels were apparently normal, the ventricles empty and no changes in the basal ganglion. Save for some paleness there were no changes in the thoracic nor abdominal viscera. Cultures on glycerin agar and nutrient gelatin from the interior of the growth remained sterile.

Microscopic examinations of the cerebral growth: Specimens were hardened in alcohol and sections made, including some of the surrounding brain and the new tissue down to the area of necrosis. There were found, engorgement of and exudation about the pial vessels. The brain structure about the growth shows the ganglion cells well preserved, some edema and a slight cellular infiltration of the perivascular spaces. Here there seems to be no increase of connective tissue. In the outer portion of the growth proper there are numerous thin-walled blood vessels, many of which are distended with blood corpuscles, and in not a few are leucocytic thrombi. At some points there are small areas of hemorrhage. About the vessels there is quite a marked emigration of polynuclear leucocytes, some round cells with solid nuclei, and a considerable number of cells containing rounded or oval, clear, vascular nuclei of variable sizes; only a few are spindle shaped. These latter cells are most numerous just outside the vessels, although some are remote from them, and are most likely proliferated endothelial cells arising from the perivascular lymphatics. Such an interpretation is born out by the pressure of collections of similar clear nuclei here and there, having an arrangement much like the nuclei of giant cells of tuberculosis, but upon close examination there is no cell body, while a central lumen is present around which the nuclei are radially arranged. They would seem then to be proliferated endothelia of lymph vessels. The multipolar ganglion cells are present in the growth, showing a location in the brain rather than upon it. They are often necrotic, presenting nuclear fragments. The portion nearer the central softening is more edematous, there are fewer vessels and the exudative and proliferative cells are less numerous. Here the nuclei are often absent or faintly stained, the cells staining diffusely with eosin.

There are no caseous areas nor giant cells so suggestive of tuberculosis. It is also worthy of note that there is little attempt of fibrillation of the connective tissue cells and consequently slight production of connective tissue fibers.

To sum up: The growth consists of granulation tissue which is edematous and necrotic in the interior, while in the outer portion the tissue approaches more nearly the adult type of connective tissue, there being less edema and necrosis and some attempt at fibrillation of cells. Sections stained in fuchsin-anilin water, decolorized with 5 per cent. sulphuric acid and alcohol. Contrast stain with methylene blue, and examined with one-twelfth oil immersion lens and No. 3 eye-piece, Leitz, showed no tubercle bacilli or other organisms. In the absence of any structure suggestive of tumor, likewise the absence of tubercle bacilli or tuberculosis in any of the organs, it seems one is justified from the findings to say that cerebral gumma is the most probable diagnosis.

## A CASE OF CEREBELLAR ABSCESS, SINUS PHLEBITIS, AND SUPPURATIVE OTITIS MEDIA.

Read before the Chicago Pathological Society, Dec. 10, 1894.

BY JOHN L. MORRIS, M.D.

CHICAGO, ILL.

Olof J., age 27; Norwegian; admitted to Presbyterian Hospital Oct. 4, 1894; occupation clerk; family history negative. Previous illnesses: When 14 had tonsillitis which lasted six months, ending in a tonsillar abscess, which was ultimately lanced. Three times during the past year he has fallen down in a "faint," as he describes it. These spells would last about five minutes, after which he would recover and be enabled to resume his work. Present illness began four weeks before admission to the hospital, by sudden pain in left ear followed by a chill. The earache was persistent, but for two days he continued his work, when he was obliged to take to his bed and consult his physician. Next morning he had a sudden exacerbation of pain followed by a discharge of pus from the left ear. On this day he first noticed a slight frontal headache which has gradually increased in severity. On this third day of his illness he vomited his dinner. Subsequent to this he had vomited about once each day. Four days afterward he had a second chill, after which he was delirious, the delirium lasting about ten days. During this delirium he had four or five chills at irregular intervals. At this time, owing to the masked symptoms presented, a diagnosis of probable typhoid was made by his physician. Up to the time of admission to the hospital he had had no dizziness, earache or other subjective symptoms; was constipated, but had good appetite.

On admission to the hospital, his condition was as follows:

Pulse 66, temperature 90, respiration 20; countenance pale, drawn and anxious; breath, fetid; tongue foul and extremely red; eyes closed, as patient explained, to exclude the light; intellect slightly dull and sluggish, but perfectly rational when addressed; eye and face reflexes normal; no tender points discoverable about ear or cranium; abdomen boat shaped. An extremely foul odor emanated from the left external auditory meatus; discharge slight if any. Internal jugular on left side was palpable as a whip-cord-like structure, and seemingly much engorged.

Urinary analysis: Specific gravity, 1020, trace of albumen, extremely foul odor, and large quantities of biliary coloring matter.

During the first eight days after admission into the hospital, temperature from 98 to 94.6 degrees F.; pulse ranged from 70 to 50, respiration 20 to 16. Enematas were always necessary; urination free and sometimes involuntary; vomited almost regularly once each day and always after eating a few mouthfuls; vomit would be projectile and sudden.

Patient when placed upon his feet would stand steadily with eyes open or closed; no ataxia; knee jerk normal; fundus of eye was not examined; at regular intervals would suffer extreme exacerbations of frontal headache, which would always be followed by a fall of temperature to 95 or less, and by more or less drowsiness.

A diagnosis of abscess of the brain was made, but from lack of focal symptoms its locality could not

be determined, and it was deemed unwise by the consulting surgeon to operate immediately.

On October 12 convergent strabismus and diplopia were recorded; left external rectus paralyzed; left pupil irregular in outline. Patient was much brighter mentally.

On the night of October 12 the pulse went up to 120; temperature to 100 degrees and respiration to 24; patient suffering extreme pain. Under narcotics patient fell asleep about 3 A.M. At this time the pulse was regular, 94; temperature 96; respiration 16. For the next two days, with the exception of pain being more severe than formerly, patient's condition was the same as during the first eight days of his stay in the hospital.

On October 15, at 9:45 A.M., patient was examined by a member of the house staff and his condition seemed unchanged. Pulse was regular and of good quality, ranging about 70 or 75. Fifteen minutes later, patient expired very suddenly and quietly.

The autopsy was conducted by Dr. Bishop and myself. It gave the following information: Meningeal vessels much injected, no external bulging; ventricles negative. On lifting the brain about an ounce of pus escaped from under the cerebellum from the vicinity of the left lateral sinus; although great care was used in delivering the brain it was impossible to state whether the pus was free or not. In the anterior part of the left hemisphere of the cerebellum an abscess about the size of an English walnut was found in the substance of the cerebellum. The meninges evidently formed the inferior wall of the abscess. The groove for the left lateral sinus was filled by a plastic phlebitis for about the distance of an inch above and below the abscess. Any connection between the abscess and the internal ear was undiscoverable. The interior of the petrous bone was found to be filled with inspissated pus and osteo-porotic cancellous tissue. All organs and contents of thorax and abdomen negative. Stab cultures from the escaping pus, from the interior of the lateral sinus and from the abscess cavity were made. Bacteriologic investigations of these cultures were conducted by Dr. Weaver who was unable to demonstrate anything more than a putrefactive organism. The organisms from the three sources were demonstrated to be the same.

## A CASE OF NODULAR TUBERCULOSIS OF THE CEREBELLUM.

Read before the Chicago Pathological Society, Dec. 10, 1894.

BY E. R. LE COUNT, M.D.

CHICAGO.

Clinical history kindly furnished by Dr. F. J. E. Ehrmann, Resident Staff, Cook County Hospital:

Wm. B., single; white; age 28; English. Admitted to service of Dr. Earle August 19, 1894. Stated that he had been out of work since March, on account of persistent neuralgic pain in both fore-arms. Of late, has complained a good deal of headache; tenderness over occipital region. Had gonorrhea three times; chancre three years ago. Mental condition apathetic; sleeps most of the time and only with difficulty aroused. Eyes, pupils dilated and react slowly. Eye grounds show distended veins on each side. Tongue broad and flabby. Chest, examination negative. Abdomen, negative. General condition good; well nourished. When aroused, answers questions intelligently. Headache worse on motion; no pain

elsewhere. Pain in occipital region radiating toward frontal region. Urine amber colored, acid, 1015. no albumen. Temperature varied between 96.4 and 99.4; as a rule, was below normal. Pulse 64 to 80; respiration 20.

Patient continued in this condition until September 23, when death occurred. Gradually apathy merged into stupor, a semi-comatose condition, and full coma.

### NECROPSY.

Necropsy showed several (six to eight) nodules the size of small hazel nuts in left cerebellar lobe, some separate entirely from others; some deeply seated, and others in connection with the meninges. On section, these showed softened centers. There was also tuberculosis of the lungs; exact form and degree not stated.

Microscopic examination: Well marked necrosis; non-staining centers to all nodules examined; surrounding zone of round cell infiltration not very marked; very few giant cells and those not typical of those seen in tuberculosis elsewhere; tubercle bacilli found by staining with carbo-fuchsin and methyl blue—not numerous, found only in periphery areas of necrosis in the zone of round cells.

Conclusion: Tuberculosis of the cerebellum, corresponding to what is known as solitary tubercle. But there were more than one, and some were isolated from others and therefore the term, nodular tuberculosis, meaning areas of tuberculosis larger than the usual forms of tubercles would perhaps not be inappropriate.

### DISCUSSION.

Dr. A. R. EDWARDS—I was especially interested in the case Dr. Le Count reported, because of the fact that Dr. Ehrmann, of the house staff, and myself, had an opportunity to study the case clinically and make an ante-mortem diagnosis of the tumor, as well as its location. There are several points in the clinical history that were not recorded on the history sheet, of which I have notes. Although the patient was markedly paretic on both sides of the body, there was absolutely no localized paralysis in any member. Furthermore, there was no disparity between the two sides, the ocular muscles were perfectly normal and the reflexes were but slightly increased. There was no persistent vomiting, the patient vomited only once. We noted, from time to time, that there was never a slowing of the pulse. The patient complained of vertigo, even when he sat up in bed; "saw things moving around," as he expressed it. Regarding the ophthalmoscopic examination, not only were the retinal veins greatly engorged but the arteries were decidedly small, and there was, in addition, a small patch of choroiditis in the right eye. Here and there through the retina was a reddish color, and even opalescence of the disk, so that the condition was illustrative, not only of choked disk but also of optic neuritis and retinitis. Besides that there was one feature among the few focal symptoms which put us in the direction of making the local diagnosis; the fact that motion, so far as the head was concerned was perfectly free from side to side, but it hurt him considerably to throw his head in a forward direction. That suggested some affection in the posterior fossa. Then with the vertigo and ataxia, the marked choked disk and this stiffening of the muscles of the neck, as well as the localized tenderness there, the diagnosis was made of a cerebellar tumor. As to the nature of the tumor, an abscess was thought of. The patient declared that he had never had any venereal disease. Examination of the ears showed nothing abnormal. He had no temperature, and nothing in the periphery of the body or in the heart that would make us think of metastatic abscess. Syphilomata are not as frequent in the cerebellum as elsewhere. His gait was ataxic.

A careful and thorough anti-syphilitic treatment was instituted; two careful inunctions being given, one in the morning and one at night, and he was given large doses of iodid. That was continued three or four weeks, with absolutely no improvement up to the time the patient died.

Dr. F. J. EHSMANN—I have nothing to add to the report,

except to say that the patient died unexpectedly; how that can be accounted for I do not know; it might have been caused by pressure on the medulla.

DR. SANGER BROWN—These cases have certainly been very interesting to me. In the case of Dr. Le Count it seems to me very rare discrimination was displayed in arriving at the diagnosis by exclusion and in other ways, but I think I should hardly have felt warranted in being so certain as to the position of the tumor as they seem to have been, inasmuch as the ataxia does not seem to have been strictly a cerebellar ataxia. It would seem to me, from the description given, that it might have been accounted for by the vertigo. It is a generally conceded fact that the cerebellar gait or cerebellar ataxia does not occur unless the middle lobe of the cerebellum is affected, and it appears that the middle lobe of the cerebellum was not affected in this case. It seems, in fact, that the symptoms were more particularly due to irritation than to pressure. Another point might be mentioned in this connection, and that is that in tumor of the cerebellum the knee-jerks are generally absent, and they were not absent in this case. A few months ago we had at the Post-Graduate Medical School a case of optic nerve atrophy and blindness, with persistent turning to the left and a cerebellar gait where the tendency was to sway. She did not complain particularly of vertigo. The knee-jerks were entirely absent. I made a diagnosis from the history, and for various reasons, of cerebellar tumor and the post-mortem justified the diagnosis. Within two or three weeks we had a case very similar in many ways, in which there were no focal symptoms but optic nerve atrophy and loss of the knee-jerk, and again I diagnosed cerebellar tumor. There was evidently a growth within the cranium somewhere, but the autopsy showed a large cerebral tumor in the anterior lobes, so the diagnosis in that case was entirely wrong. It appears, however, that at the operation, after I had made my examination the operator was given a history of some sensory symptoms in one side of the face and in one arm, and he operated on the supposition that there was a tumor adjacent to the motor area, and he was right.

It was noted in the case reported by Dr. Morris, which was extremely interesting, that there was no ataxia, and yet the disturbance in the cerebellum must have been very much greater than in the last case. The variations in temperature and the subnormal temperature I think were very interesting, and it ought to be recorded as an interesting clinical fact for which at present we can offer no sort of reasonable explanation.

The case reported by Dr. Brower, of gumma of the cerebrium, was to me exceedingly instructive, and I do not think we would be warranted in regarding Dr. Brower's diagnosis as a mistake. I can imagine how very much surprised he must have been, with that array of symptoms, to find nothing on the surface of the brain, but the growth was just beneath the surface involving the tissues and the fibers passing off. I did not learn in that case the condition of either the knee-jerk or the fundus.

DR. BROWER—The fundus was normal. The knee-jerk was slightly exaggerated.

DR. BROWN—It would not be necessary, with the symptoms that were present, to examine the fundus in order to make a diagnosis, but it is always interesting to have the examination as complete as possible. I did not learn whether great pain in the head was complained of or whether there was vomiting.

DR. BROWER—There was no vomiting and no special pain in the head after the onset of these symptoms; the man had had headache for several years previously.

DR. BROWN—I should think that would make the case very much more interesting, more unique. How could such a tumor have existed (and it must have been a considerable time in forming) without producing one or two of the three cardinal symptoms in cerebral tumor, that is the focal symptoms, the paralysis or convulsions, the vomiting and the choked disk or optic neuritis. Those are considered the three cardinal tests for cerebral tumor.

DR. H. T. PATRICK—These cases have been very interesting and I wish to add just a word. Bruno, several years ago, called attention to the fact that large tumors in the frontal lobes do cause the cerebellar gait and other symptoms attributed to the cerebellum. Regarding the case of Dr. Brower, I beg leave to take exception to what I understood to be the meaning of Dr. Brower and Dr. Bishop as to the place of origin of the tumor; that it sprang from the centrum ovale. I think the position of the tumor, as well as the origin of most cases of gummata would lead us to sup-

pose it sprang from the meninges of the surface and grew inward, which illustrates a very important point, not sufficiently emphasized, that cortical epilepsy, so-called, is often produced by subcortical lesions. This is of importance, not only in making the diagnosis but in the treatment of these cases by operation, because I think it necessitates a large opening of the cranium and if nothing is found in the cortex, at least on the surface, it is advisable in most cases to make a free incision in the brain. This has been shown to be not a serious traumatism; if the incision is made parallel to the fibers leading from the surface, it adds little risk to the operation, does small damage to the patient and increases the possibility of finding a lesion. In this case I think such a procedure would have led to the discovery of this tumor because just beneath the cortex, in the arm center, which was the suspected location, was an area of secondary softening due to the tumor which would have been found and probably have led to the discovery and removal of the tumor. In connection with this, in cases of Jacksonian epilepsy, the fits may be caused by a very small lesion in the center corresponding to the fits, or a larger lesion in the neighborhood, so that in many cases the lesion is not to be sought for, necessarily, in the center corresponding to the convulsions. Another point I would call attention to, is that in many of these cases the symptoms are not due to the growth but to a secondary vascular trouble, softening ordinarily, and the hemiplegia in Dr. Brower's case was due, not to the increase in the size of the growth, but to the secondary softening which was easily perceived beneath the tumor, interfering with the motor fibers. For this reason I think it is particularly important to make a diagnosis as early as possible and to be on the lookout. I have a case now under observation, of a man who suffered for a couple of months from severe and constant headache. There were no focal symptoms whatever except slight numbness on the right side, followed by a very slight weakness which did not incapacitate him from work, and shortly before I saw him a very slight degree of aphasia. He was seen by two excellent physicians; the first recognized no cerebral trouble, the other did very promptly, but he did not examine the man's eyes or he would have found a choked disk and could have submitted him to an active specific treatment which would have saved time later. Two days afterward the man had a sudden attack of right hemiplegia, right hemianopia, right hemianesthesia and very marked aphasia, assisting very greatly in localizing this trouble which indicated a large area of destruction. The question at once arose whether the man should be operated upon immediately or whether we should wait. The hemiplegia almost passed off in two days, and the question was still whether we should operate at once or submit the man to specific treatment and wait. We decided to wait, put him on large doses of iodid and two days later he had another attack, a very extensive softening with complete right hemiplegia and he is now in a most deplorable condition; whether syphilitic or not he has very little to gain from an operation of any kind.

DR. H. N. MOYER—I would like to make one remark relative to the case of Dr. Le Count. It seems to me that is a case of rare interest and one very well stated. It has been customary to regard the lateral lobes of the cerebellum as not being concerned in the production of the ataxic gait when they are involved; that is, if the middle lobes and middle peduncle remain free there is commonly no ataxic gait. But I think we shall have to recede from this position somewhat. A case has been published recently, of sclerotic patches in the lateral lobes of the cerebellum, with the typical ataxic gait, the middle peduncle or angles of the root remaining entirely free from any involvement in the process, it being confined entirely to the cortical regions of the lateral lobes. This is a case almost parallel to Dr. Le Count's case. I think it of rare interest as it serves to help clear up some of the doubtful and obscure pathology of the cerebellum.

DR. EDWARDS—As to the size and weight of the tumor in Dr. Le Count's case, although it did not grow in the portion of the cerebellum spoken of by Dr. Brown, when divested of all cerebral tissue it weighed forty grammes, and from the fact that the tumor was nearly the size of an egg, it does not seem hard to understand how, although anatomically it did not originate in the part of the cerebellum which is supposed to produce ataxia, yet by secondary pressure it could cause true cerebellar symptoms.

DR. BROWN—I had a wrong idea of the size of these growths. I thought they were small and not capable of causing such pressure as the Doctor speaks of. But since he speaks of the

tumor being nearly the size of an egg, it is easy to understand how the functions of the middle lobe might be seriously interfered with.

DR. BROWER—There are one or two things that suggest themselves to me in the further consideration of this gumma. I think the growth was a very rapid one. Some of the speakers thought it was a slow growth but I think it was very rapid. The first symptoms of any great brain disturbance, except headaches which he had irregularly for many years, occurred on October 19, and he died on November 23. He had his first convulsion, in which he lost consciousness, on October 19 and as soon as possible after that his physician brought him to Chicago for further advice in the case. I saw him on October 23, the fourth day after he had his first convulsion and I doubt very much whether there was any growth to amount to anything there at that time. As to the origin of the growth that is a matter of speculation, but I am very much of the opinion of Dr. Bishop that it is a growth beginning in the centrum ovale, rather than in the meninges, because I believe if that growth had begun at the cortex in the leg center where it is located, we should have had more disturbance of the lower extremities. Except in his first attack, when the convulsions were general, it was very uncommon for this spasmodic movement to extend beyond the muscles of the hand and the fore-arm, rarely involving the face and very seldom indeed the leg. I suppose I saw him in a dozen of these attacks in the ten days he was here and I noticed no spasmodic movement of the face and none of the leg. It seems to me if this tumor had had its origin at the cortex in the leg center where it was located, and involved the fibers from the arm center secondarily, that the symptoms would have been somewhat converse; we ought to have had more spasmodic movement in the leg and less in the arm, but so far as my observations were concerned there were no movements in the leg at all. The hemiplegia began with the arm and in the course of thirty-six hours involved the entire side of the body. So taking the array and succession of symptoms, I should be inclined to suppose that it began in the centrum ovale. There was no improvement in the hemiplegia after it began. All the symptoms disappeared under the use of large doses of iodid of potassium. I am quite sure the tumor must have made rapid growth.

DR. LE COUNT—In regard to the size of the cerebellar tumors, there were eight of these tumors found and they would average a centimeter to a centimeter and a half in diameter, so that would make quite a mass in the left lobe that certainly could cause pressure upon the middle lobe of the cerebellum. These tumors were more or less spherical, and it was for this reason that I gave the title of nodular tuberculosis, which does not seem to me to be inappropriate. Tuberculosis may affect the cerebellum or the cerebrum. The usual form is tubercular meningitis. We have very rarely a diffuse tuberculosis throughout the substance of the cerebellum or cerebrum, and occasionally this form of nodular or solitary tuberculosis. As there was not a single area, I thought the title of solitary tuberculosis was not appropriate. The discussion, as usual, has taken mainly a clinical aspect. I would have been glad if it had to do with the etiology at least of these cases. The consideration of the primary focus in the cerebrum and cerebellum is considered very conservatively by most authors. Osler mentions it as occurring. Simon, of Nancy, last year made twenty-seven post-mortems in cases of tubercular meningitis and in twenty-five was able to demonstrate a primary focus elsewhere. The primary focus in this case was probably in the lungs. The bronchial glands were found enlarged. The next question that arises is, What is the course taken by the infection to reach the cerebellum or cerebrum? In the majority of cases certainly by way of the lymph vessels, as Weigert has shown in investigating the location of tuberculosis. Then what is the route of the infection in a case of this kind? If we are to presume tubercle bacilli in the lymph vessels, why not a tubercular meningitis and death before we have time to obtain such gross areas as this. On the other hand, if we suppose infection by way of the blood vessels, we must take into consideration the fact that there are probably but few bacilli in the blood vessels and they locate at one point and in this way we have time for the development of large gross or nodular areas of tuberculosis. Concerning extension by way of the lymphatics, the most usual route, I have been unable to find anything in the literature.

## ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 366.)

### CHAPTER VII.

#### CONSTITUTION AND CHANGES OF THE BLOOD IN YELLOW FEVER.

*Recapitulation.*—Facts illustrating the changes of the blood during the active stages of yellow fever. Alterations of the chemical and physical properties of the albumen and fibrin. In many cases complete disappearance of the fibrin. The disappearance of the fibrin appears to be due, not so much to the action of ammonia, which is so often found in the blood of yellow fever, as to the direct action upon this element, of the febrile poison. Character of the blood in the cavities of the heart after death. The alterations in the physical and chemical properties of the fibrin and albumen, lead to transudations through the excretory structures of the kidneys. While the colored blood corpuscles are not specially diminished in yellow fever, they present under the microscope certain peculiar appearances which are referable to the action of certain extraneous excretory matters in the blood. Extractive and fatty matters increased in yellow fever blood. Bile accumulates in the blood, in consequence of the profound lesions of the liver induced by the febrile poison, and in consequence of the failure in the excretory power of the kidney. The serum presents a golden yellow color in yellow fever. Accumulation of the urinary constituents, and especially of the urea and phosphoric acid, sulphuric acid, chlorid of sodium and carbonate of ammonia, in consequence of the profound lesions induced by the febrile poison and its products upon the kidney. Breath alkaline from presence of ammonia. Blood corpuscles rapidly dissolved, after the abstraction of the blood. Blood of yellow fever undergoes rapid putrefaction. Cases illustrating the changes of the blood in yellow fever. Observations illustrating the changes of the organs in yellow fever and in malarial paroxysmal fever. The colored blood corpuscles are not specially destroyed in yellow fever, as in malarial fever. The nervous symptoms of yellow fever referable chiefly to the presence of bile and the constituents of the blood in the urine. Causes of death in yellow fever. Microscopic character of black vomit. Relations of the variations of temperature and circulation to the changes of the blood. Observations and cases illustrating the relations of the pulse, respiration and temperature. Observations of various observers, as Rush, Devoe, Currie, Caldwell, Samuel Jackson, Lewis, Arnold, Chalmers, Lining, Daniel Blair, John Davy, Faget, Leighton and Lyons. The cause of the rapid rise and declension of the temperature in yellow fever must be sought chiefly in the changes induced in the blood, and in the organs upon which the circulation and integrity of the blood depends. Neither the rapid rise, nor the sudden declension of the temperature can be referred wholly to the effects of the yellow fever poison upon the nervous system. Discussion of these propositions.

That the blood undergoes profound changes during the period of febrile excitement of yellow fever is manifest even to the casual observer, in the impeded capillary circulation, purplish, jaundiced and dusky hue of the surface, livid blotches, passive hemorrhage from slight abrasions, leech bites, blistered surfaces, and hemorrhages from the ears, eyes, mouth, gums, and gastro-intestinal mucous membrane, which in some cases are characteristic of the succeeding period of calm or exhaustion.

Although after the subsidence of the fever, at the end of from two to five days, the skin becomes cool and pleasant, the tongue shows a disposition to clean, and the tips and edges are less red, the thirst abates, and appetite for food returns, and the anxiety and morbid fear of death, which may have been great, subside, and both patient and bystander may regard convalescence as established; nevertheless, a careful examination, will show that the circulating fluid has

been altered during the preceding stage of febrile excitement; the eye loses its glistening appearance and assumes a condition of chronic vascularity, of a dull orange red; the flushed countenance gives way to a bloated appearance and dusky, dirty complexion; the sclerotic of the eye is jaundiced, the forehead presents a dusky appearance, which extends also over the neck and chest, the languor of the capillary circulation is indicated in the purple and lobster red condition of the skin, and by the pale marks left by pressure over the forehead, cheek, abdomen, or surface of the extremities; the matters vomited, which at first may be tinged with bile, change to a clear, acid, mucous fluid, and become discolored by small dark specks and flocculi of blood. The further changes of the blood are indicated by an increase in the purplish or yellow suffusion of the surface, and by such a loss of vitality and of the fibrinous elements as manifests itself in the raw claret-colored surface of blisters, in epistaxis, ecchymosis, bloody oozings from the mouth, ears or anus, excoriation of the scrotum, the copious ejection of dark altered blood from the stomach, with little or no apparent effort, copious stools of black altered blood, and by the foul fetid alkaline breath containing ammonia.

It appears to be an error to treat of the changes of the blood as confined to the latter stages of yellow fever, thus regarding the disease as manifesting only two grand stages, viz: that of reaction, irritation and fever, and that of unhealthy subsidence or contamination, characterized most prominently by exhaustion of the nervous system, slow pulse and passive hemorrhages.

*The changes of the blood appear to be continuous, from the time of the introduction of the poison to the fatal termination;* these changes being increased, and their character being modified as the disease advances, not only by the direct action upon the constituents of the blood by the poison, but also by the addition of certain noxious substances, as bile, urea, carbonate of ammonia, sulphates and phosphates and extractive matters.

Certain constituents of the blood, as the albumen and fibrin, are not only altered physically and chemically in the early stages of yellow fever, but as the disease advances, from the cause just specified, certain excrementitious matters, which in a state of health are continually eliminated accumulate in the circulating fluid, and by their direct action upon the elements of the blood, and upon the nervous system, and by their disturbing action upon the processes of digestion and nutrition still further alter the physical, chemical and vital properties of this fluid.

As far as my observations extend, the alterations of the blood in yellow fever consist chiefly in:

1. Such an alteration of the chemical and physical properties of the fibrin and albumen as leads to the transudation of the latter through the excreting structures of the kidney.

2. Various degrees of alteration and diminution of the fibrinous element.

In some cases there is an almost entire disappearance of the fibrinous element. This disappearance of the fibrinous element appears to be due not so much to the action of ammonia, which is so often present in abnormal amount in the blood of yellow fever, but in the direct action upon this element of the febrile poison. From this alteration in the amount and character of the fibrinous element it re-

sults that the blood coagulates imperfectly in most cases, and the clot is voluminous and soft. The amount of serum formed is small, and upon standing, the clot frequently dissolves, leaving a thick, non-coagulable grumous blood. The blood taken from the cavities of the heart and large blood vessels after death is frequently black and fluid; and if, as is sometimes the case, fibrinous concretions are formed in the cavities of the heart, they are small, soft, and of a bright golden yellow color, and much smaller in size and less firm than is usual in attendant diseases near the fatal issue, with similar retardation of the circulation in malarial fever. In the latter disease the formation of firm, light colored blood clots is, as I have shown, by a large number of observations, not only frequent, but also a cause of death in certain cases of pernicious malarial fever.

3. While the colored blood corpuscles are very slightly diminished in yellow fever, they present under the microscope, certain peculiar appearances, which appear to be referable to the action of certain extraneous matters in the blood.

4. Increase of the extractive matters of the blood.

5. Increase of the fatty matters.

6. Accumulation of bile in the blood, in consequence of the profound lesions of the liver induced by the febrile poison, and in consequence of the failure of the excretory function of the kidneys. Many of the changes of the blood, as well as certain cerebral symptoms, may be dependent upon the presence and action of the biliary constituents. Even the nausea and vomiting, as well as the depression of the pulse, and the nervous agitation, delirium and coma, may to a certain extent be referred to the same cause. The serum presents a golden color in yellow fever. This condition of the serum is due to the presence of bile and may be present also in grave cases of paroxysmal malarial fever. If a drop of yellow fever blood be allowed to fall on a piece of bibulous paper the center will appear of a brilliant scarlet, while around the central accumulation of colored blood corpuscles extends a ring of bright golden colored serum.

7. Accumulation of the urinary constituents, and especially of the urea and phosphoric acid, sulphuric acid, chlorid of sodium and carbonate of ammonia, in the blood, consequent upon the profound lesions induced by the febrile poison and its products upon the kidneys. Not only is the blood alkaline in many cases of yellow fever, but the blood contains ammonia, resulting from the decomposition of the urea, the presence of which may be rendered evident by various means, as by the addition of potassa, soda or lime; and in some cases the ammonia is so abundant as to be demonstrable without resorting to these reagents. As the phosphoric and sulphuric acids are retained in the blood when the function of the kidneys is embarrassed or suppressed, they unite with the ammonia and thus diminish the alkalinity of the blood and render the addition of potassa or soda or lime necessary in certain cases for the demonstration of the ammonia. The reaction of the yellow fever blood is alkaline during life, but it rapidly changes in some cases to the acid reaction after death, from the rapidity of the putrefaction, and also from the development of numerous forms of low organization.

8. Rapid dissolution of the colored corpuscles, after the blood is abstracted from the body, either

Patient.	Age.	Referred by	Principal Symptoms.	Diagnosis.	Free HCl.	Lactic Acid.	Total acidity	Principal germs found.	Remarks.
B. F. D. . . . .	22	Dr. Newman . . .	Vomiting, gas, pain.	Stenosis, dilatation. . . . .	1 hr. after meal.	Ether ext., Uffelmann's. +	60	Sarcinae in great quantity . . . . .	Sarcinae found in fasting stomach, forming a great mass.
Mrs. McC. . . . .	45	Dr. Newman . . .	Diffuse pain, great distress after eating, depression. . . . .	Gastritis, beginning atrophy. . . . .	—	Ether ext. +.	40	Micrococci, short and long rods. . . . .	Great number of wedge shaped colonies of micrococci.
Mrs. J. B. . . . .	47	Dr. Bacon. . . . .	Prickly sensation in stomach, headache, anorexia. . . . .	Gastritis, beginning atrophy. . . . .	—	Ether ext. +.	32	Small rods like bacilli coli com. yeast, lactic acid germs. . . . .	Could not exclude carcinoma at first; after two years patient showed no signs and HCl .11% . . . . .
Annie S. . . . .	31	Dr. Martin. . . . .	Pain in epigastrium, dizziness, headache	Chronic parench nephritis. . . . .	—	No lactic acid by Boas' method.	15	Nothing marked beyond a few rods; no cultures made. . . . .	Gastric symptoms so severe to mask all disturbance; albumen traces hyalin and gran. casts.
Dr. . . . . .		Dr. Martin. . . . .	Distress 1 hour after eating, depression, loss in weight. . . . .	Tuberculosis pul (?) . . . . .	—	Ether ext. + faint. . . . .	30	Large number of tubercle bacilli. . . . .	The tubercle bacilli appeared in contents of S. drawn off.
Wm. B. . . . .	46	Dr. Hall. . . . .	Paroxysms of gastric radiating; nervous unrest. . . . .	Neurosis . . . . .	+	—	90	Mixed variety, few microorganisms, no cultures. . . . .	As only the usual appearance of a few germs distributed here & there, no bacteriologic study was made.
M. P. . . . .	43	The General Medicine Clinic . . . . .	Uneasiness in region of stomach, anorexia, loss in weight, night sweats. . . . .	Carcinoma of the pylorus. . . . .	+	Extract with ether, with Uffelmann's reagent. ++	55	Lactic acid forming bacilli; long and short rods, threads; curved bacilli. . . . .	Four exam. made 9 mos. after HCl negative; tumor pylorus; patient left city, reported dead.
Mrs. D. H. . . . .	38	Clinic. . . . .	Rapid loss in weight, gastralgia. . . . .	Withheld for further examination.	+	Boas' method .05+; two analyses made.	35	Few lactic acid germs. only appeared in milk and starch culture. . . . .	First attempt no lactic acid forming germs appeared, on second attempt few found.
Chas. W. C. . . . .	39	Clinic. . . . .	Vomiting as soon as he took food, loss in weight . . . . .	Chronic interstitial gastritis . . . . .	—	—	Very weak pepton	Staphylococcus and streptococci, short rods like bacilli coli communi. . . . .	Stomach just below costal arch by gyromele exam. held only 350 c.c. water.
Mrs. C. S. . . . .	37	Dr. Sanger Brown.	Bloating, dyspnea especially at night, headache. . . . .	Gastro-enteroptosis . . . . .	+	—	43	Black and red yeast colonies, gas forming. . . . .	Symptoms disappeared after disinfection.
A. L. B. . . . .	34	Dr. Kirkpatrick. . . . .	Distress shortly after eating, rapid emaciation, pale, approaching cachexia.	Carcinoma ventriculi. . . . .	—	Boas' method 0.95% by Dr. Wesener. . . . .	...	Lactic acid bacilli, threads, short rods, micrococci. . . . .	Diagnosis not confirmed, laparotomy advised.
Mrs. M. W. . . . .	61	Dr. Ayers. . . . .	Pain in epigast. region radiating to the right side. . . . .	Gastro-enteritis, chronic, with atrophy. . . . .	—	Boas' method 0.055% . . . . .	20	A number of colonies of bacilli like the coli communi. . . . .	The cultures gave culture medium an acid reaction.
Mrs. B. R. . . . .	32	Dr. Brower. . . . .	Late gastric symptoms of tuber. pul.	Tuberculosis pul.	—	Uffelmann's (negative) . . . . .	9	Tubercle bacilli in great numbers in stomach contents. . . . .	Could not determine colonies, only what might be swallowed.
Mrs. L. . . . .	54	Dr. Babcock. . . . .	Cardalgia, belching, pyrosis, headache, insomnia. . . . .	Gastroptosis; gastritis gland. chron. . . . .	—	Uffelmann's —	69	Several forms yeast, gas forming; wedge shape colonies of micrococci, lactic acid only in one milk culture. . . . .	Great number of leucocytes.
Mrs. H. S. . . . .	28	Dr. Newman . . . . .	Burning sensation in stomach, gas, emaciation, stagnation of food. . . . .	Gastritis gland. chron. stenosis, dilatation, gastroptosis. . . . .	+	—	60	Sarcinae ventriculi, many other forms but masked by the sarcinae. . . . .	Hyper. of pylorus operation, pyloroplasty advised.
F. S. . . . .	24	Dr. Gehrman. . . . .	Dull heavy feeling after eating, remnants of food 20 hrs. after eating. . . . .	Stenosis (?) (no marked extension) hypersecretion. . . . .	+	—	80	Cladotrix. Algae (rivularia, nostoc communi) cultures in water. . . . .	Stomach contents were a rich dark green; after filtering and introducing the algae into the gastric juice, developed rapidly.
Flora S. . . . .	21	Dr. Newman . . . . .	Headache, gas, gastralgia, emaciation.	Dilatation. . . . .	+	—	50	Same as above yeast. . . . .	Light green contents found at night after washing S. in morning; nothing eaten during day.
J. S. McC. . . . .	27	Dr. Sanger Brown.	Constant pain in epigastrium emaciation.	Dilatation, hypersecretion. . . . .	+	—	70	Algae gelatinous fronds in unicellular masses, threads and spirillae; yeast. . . . .	First exam. dark green, after two treatments light green contents from empty stomach.
G. K. . . . .	23	Dr. Melms. . . . .	Constant pain in epigastric region. . . . .	Dilatation, constant flow. . . . .	+	—	112	Similar to above; develop in water a drop dil. ammonia; will not develop when HCl .1% added to water. . . . .	Green fluid; removal by use of liquid soap, and gyromele; lavage retards but green color returns in a day or two.

The work here presented, represents cultivations made over a period of two and a half years.

There seems to be a law in the growth of germs in the stomach as in artificial cultivation, viz., those colonies will take precedence and predominate when

the culture media and other conditions are most favorable for the development of these special classes and varieties. Sarcinae grows best in a dilated stomach with benign stenosis, even where an excess of HCl is formed, whereas outside the stomach the

sarcinæ grows better in an alkaline medium. The fact of the HCl being in excess can not be considered as a reason, but the culture medium is so fertile for the growth of sarcinæ that they rapidly develop in vast numbers, even in this acid medium. It may be that these and other microorganisms that develop with the sarcinæ may excite and cause hypersecretion and the excess of HCl. In the dilated stomach, without stenosis, are often found algæ, cladotrix, and various saprophytes which grow with great rapidity, while other microorganisms take second place. Many forms of yeast thrive well in these cases of simple dilatation many of which are gas forming and differ from sarcinæ ventriculi. In carcinoma, the lactic acid forming bacteria seem to thrive best, and though found in other conditions, yet as sarcinæ thrive best in benign stenosis, the lactic acid microorganisms like better a malignant stenosis.

It is impossible at present to consider infection of the stomach as due to any specific microorganisms. Gastritis glandularis chronica is an inflammatory process excited by various etiologic factors and the process is kept up so long as conditions permit certain groups of microorganisms to colonize. When stenosis occurs, one class seem to predominate, viz., sarcinæ ventriculi, of which there are five varieties. Sarcinæ are found in other diseases besides benign stenosis, but in this class they seem to have the best possible conditions for rapid development. In some cases it seemed as if the entire contents, measuring from 100 to 500 cc., were made up of these packet-shaped microorganisms.

In carcinoma, especially of the pylorus, the lactic acid forming bacilli take precedence. The other varieties are present; in fact an inflammatory process is set up, in all appearances of an infectious nature, but when the experiments and bacteriologic evidence present so constantly the presence of the lactic acid microorganisms in a greater number of colonies than are found in the other diseases of the stomach, it presents startling evidence of considerable diagnostic value, as markedly at least as sarcinæ found in benign stenosis.

I have observed five varieties: Small rods, rounded ends; long threads, unequal lengths: a short slightly curved bacterium; micrococci, and a macrococcus. There are a great number that can produce lactic acid when the media is suitable. There is one class of infection in the stomach which seems to markedly alter the glandular tissue by direct irritation as a chronic inflammatory process. Another class in which the stomach acts as an incubator, producing no great disturbance to the gastric wall, but the absorption of the products formed produce profound general poisoning. Both of these conditions may be present at the same time, or one may overshadow the other.

In experimenting with lactic acid cultures in the stomach of animals the results are not very brilliant. In the dog it is very difficult to grow them—whereas the sarcinæ and the red and black yeast will grow in the stomach if a certain condition is produced.

#### EXPERIMENTS ON DOGS.

Experiment 1: Introducing three tube cultures of sarcinæ into a healthy dog's stomach. No sarcinæ could be found after the lapse of forty-eight hours.

Experiment 2: Tying off the pylorus enough to produce marked stenosis, but not complete.

Introducing three cultures: 1, sarcinæ; 2, red yeast; 3, black yeast.

Result: The microorganisms were found within forty-eight hours, but by no means proliferating.

Experiment 3: Introduced tannic acid into a dog's stomach, applying to the entire wall with the gyromele daily for one week. As this is the first step in the experiment to produce artificial gastritis, I introduced the contents from the stomach of patients suffering from chronic gastritis. As soon as the animal showed signs of loss of appetite, refused to eat meat, and grew thin, the pylorus was tied off as in the other experiments. Here sarcinæ developed rapidly.

Experiment 4: The contents drawn off when introduced into a sterilized milk and put at 37 degrees C. for forty-eight hours showed lactic acid by Uffelmann's reagent +. Did not secure any pure cultures of lactic acid bacilli.

Experiment 5: Introduced algæ from cultures made in the filtered contents of stomach of patients in which algæ was found. The algæ died out.

At present it is impossible to consider algæ pathogenic. The algæ is found in a great many cases of dilated stomachs with HCl+ and hypersecretion. The Germans frequently note a green color of the stomach contents, some alluding to it as bile, but it may be that by more careful microscopic examination of the green colored contents, algæ will be found present, and by careful observation a large number of these cases can be found and classified.

In this work I can only call attention to the presence of algæ in certain dilated stomachs, for the purpose of comparison and grouping the class of microorganisms found in each particular disease. In another work devoted to this subject, I shall give the results of cultivation and classification.

Algæ require quietness and rest to develop well. When cultures are made in small bottles, carried in the pocket, the movements of the body prevent the development, whereas the same culture in a resting condition (as on a shelf), develops rapidly.

The dilated stomach in which the organisms are found shows a great lack of "muscle tone," and may act like a swinging hammock, so that comparatively little disturbance is caused in the body movements. Stagnation exists. This same condition exists in the growth of the microscopic algæ in nature. A running brook is not in as good condition for the growth, as a pool. In cleansing the stomach thoroughly until the water ran clear, and allowing the patients to fast for twenty hours, the green color appeared again in the secretion, which was found, on microscopic examination, to be due to the algæ. This was demonstrated in six cases.

To formulate a satisfactory classification of microorganisms found associated in each class of pathologic conditions of the stomach, is a most difficult undertaking. There are over thirty varieties of pathologic and non-pathologic microorganisms that can develop in the human stomach. Many are found in health and are also found shortly after birth.

(To be continued.)

THE forty-sixth annual session of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

## SOCIETY PROCEEDINGS.

## Proceedings of the First Meeting of the American Academy of Railway Surgeons.

Held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.

(Continued from page 367.)

## SHOULD A RAILWAY SURGEON BE REQUIRED TO PROCURE A HISTORY AS TO THE CAUSE OF AN ACCIDENT OVER THE SIGNATURE OF THE INJURED?—REASONS OPPOSING SUCH REPORT.

BY DR. GEO. CHAFFEE.

SURGEON LONG ISLAND R'Y, BROOKLYN, N. Y.

It is understood that papers presented before this body are not written to advertise either the writer or this institution.

There are in railway surgery, as we find throughout the broad domain of medicine and surgery, many disputed points, many unsettled questions.

That stalwart fellow—the engineer—who, for hours at a time stands at his post on the engine, while the vestibule flyer is being hauled across great stretches of our country, knows very well the character of the track before him, the nature of the different grades and curves. So too, the captain of an "ocean greyhound" must know well the course over which his vessel must pass, to insure his passengers comfort and safety.

The railway surgeon, in turn, should not only have a fair knowledge of medicine and surgery, but he should as well know something of medico-legal questions; for the course over which his bark may drift is often quite rocky.

One object of this institution is to seek for Truth; another, is to see that Justice be allowed to sit supreme on her throne. If this institution should ever adopt a motto, let "Railway Surgery, Truth and Justice," compose not only the framework, but the entire front, from the ground floor, up. Let us, then, ever be found ready to aid in working out difficult problems, in sifting the good works of others, in selecting truths and valuable facts for the advancement of railway surgery. I have said that in this line of surgery we have disputed points. Reference to our program will show that the topic under discussion is one of them, or this paper would not have been written.

Now I assure you, that the grounds I shall take, and the effort I shall make in the discussion of this question, are not for the purpose of outdoing my opponent in any respect. It is simply with a desire that we may after sifting, secure enough grain to establish a standard by which all may be guided in the future. I shall first follow a line of reasoning, or rather of inquiry, looking in the direction of the injured person.

## THE INJURED PERSON.

Railway surgery compels us to give our first aid to the injured. So we will first consider the injured man. Now is it policy for corporation and surgeon to combine and place their work on paper and on the records of the court against an injured person? I think not.

So far, I have found little trouble in securing the full confidence of the majority of my patients, and, in the course of a few days, when they are able to talk, usually succeed in drawing from them a full and satisfactory history of their case, and this too, in a legitimate way.

In case of slight injury where the surgeon may detect a disposition on the part of the injured person to magnify his trouble and bring suit, is it not possible for him while taking the history of the case, to include in a general way, a statement from the patient as to the cause of the injury—to get the truth, which should be all he will require for the treatment of the case, for a clinical record, and for use as a witness? I think so.

One truth sworn to by either surgeon or patient, and corroborated by the other, is worth more than a thousand affidavits secured under pressure. Suppose the injured party testifies that he has refused to give his signature, and that he resented the kind offer of the surgeon? What effect will such testimony have with the jury? Granting, then, that a signature has been procured by the surgeon, what effect will it have on the injured person? Will he not think that his surgeon is unduly exercised over his case, and will it not arouse suspicion, and at once suggest to his mind litigation? Will not such a course create a prejudice in his mind against the corporation, and will it not call forth unjust and unnecessary criticism from both friends and the public?

Having signed a paper and coupled with it delay, will he not feel or perhaps imagine that he has entered into bonds, or been drawn into a contract whereby he may have been taken advantage of, that perhaps his injury is even of a more severe character than he has been taught to believe, and, as a result—in some cases—may we not get anxiety, worry, and possibly a deranged condition of the mind? May we not aid in developing traumatic neurasthenia, or a hysterio-neurasthenia, which will place the case in the hands of the neurologist, and which alone might eventually be the means of his bringing suit for many times the amount of the original injury? I repeat, that in some cases I believe it is possible for such a turn of affairs to take place.

I am aware that the last question which I have raised carries our investigation into a delicate field. Not only does it take up the physiologic element of the topic—the effect of grief, anxiety, worry and suggestion upon the mind, which in itself would furnish material for a paper, and which I do not care to discuss further, but it also involves the economic principle of compromise.

I will, however, offer in support of the opinion which I have advanced in regard to the psychologic and economic element of this question, a brief quotation from Dr. W. B. Outten's valuable paper on "Traumatic Neuroses:" "Compensation," as viewed by the writer, "does not possess the incidental elements of worry and harassment that obtain when litigation is indulged in. We are free to confess that in our views, the influence of compromise is great. It relieves the individual of all the attendant worries incident to litigation; its influence is in the direction of mild, normal and unruffled action."<sup>1</sup>

Again, granting that the surgeon has himself procured the signature of the injured party, suit is brought and the surgeon takes the witness stand with a history of the case over the signature of the plaintiff before him, and gives his testimony accordingly. Now, what effect will this surgeon's testimony have with the jury? I think the effect will be most damaging, both to surgeon and corporation.

Having, for the time being, disposed of our injured person, let us turn whatever power we may have left in our searchlight upon the corporation, and what shall we find? We shall find among the officers of the company a surgeon, an attorney, with some a claim agent, and with others, an adjuster.

## THE DUTIES OF EACH.

Now for what purpose are these gentlemen employed?

1. The surgeon is employed to do surgical and medico-legal work.

2. The attorney or counsel is employed to do legal work, to try cases in court, to give legal advice, etc.

3. The claim agent, or adjuster, is employed to investigate all claims, to ascertain the causes of accidents, to visit witnesses, to secure all the information possible from various sources for the use of himself and the attorney, and last, but not least, to pay off claims.

I have briefly but clearly outlined the duties of surgeon, attorney and claim agent. Is it right, then, for a corporation to ask its surgeon to do the work of claim agent? The surgeon is employed, remember, to do surgical and medico-legal work. But I know you will ask, Is not this medico-legal work? Not strictly so. On the other hand, the procuring of a signature is a strictly legal procedure, having no medical status whatever; hence this fact carries the question under discussion outside of surgical and medico-legal lines, placing it in the hands of the company's attorney, or claim agent, where it justly belongs. The cause of an accident may be classed as surgical or medico-legal; but the procuring of a signature is quite another thing. It is purely legal and the work of the legal side.

I do not wish to be understood as taking the ground that it is wrong and never necessary for the company to secure the signature of an injured person. Far from it! In certain cases it may be highly essential. That, however, is for counsel to decide, and, having decided, let him do his own work, and let the surgeon keep right on "sawing wood," or rather bones, if necessary. When a surgeon lays aside the agents placed in his hands for the practice of surgery he should, for the time being, lay off the title of railway surgeon, for he virtually steps across the line from surgery to law when he assumes the task of procuring the signature of an injured person. And although his pathway while doing this work may apparently be strewn with roses of the brightest tint and sweetest perfume, I am certain that he will find upon the witness stand a chair well upholstered with the sharpest of medical legal thorns.

## TREATMENT OF BURNS OF THE CONJUNCTIVA.

BY D. C. BRYANT, M.D.

OCULIST UNION PACIFIC RAILWAY, OMAHA, NEB.

In order to come to any rational conclusions in regard to the treatment of any certain class of injuries, it becomes necessary to inquire into the nature, cause and results to be expected from the kind of wounds under consideration.

A brief glance at the causes and the conditions usually found in burns of the conjunctiva, and the consequences following them, will therefore be proper before entering into a consideration of their treatment. Before doing that, however, I will say that on account of location, direct continuity of tissue between the cornea and ocular conjunctiva, and the constant apposition of the palpebral conjunctiva with the cornea, these membranes are usually both involved in all burns of any consequence, hence in this paper the cornea will be included in the consideration of burns of this region.

Railroad employees, from the diversity of their work, take in nearly all the trades known to mechanics, and consequently are liable to any or all of the accidents common to men engaged in these pursuits and, among other injuries, burns of the conjunctiva and cornea are very common and arise from many different causes.

Among the most common agents are molten metals as iron, lead and Babbitt metals; hot metals (not melted) in the shape of scales or chips of iron, chemicals either alkaline or acid, gunpowder in many forms, hot water, steam, hot ashes, hot cinders, in fact anything possessing the requisite amount of heat or caustic properties and coming in contact with the conjunctiva or cornea. On account of the quick closing of the lids, when danger approaches the eye, only a small portion of molten metal usually reaches the conjunctiva. Be this amount large or small, unless it has become so cooled in transit as to prevent, it is immediately spread out over the anterior surface of the eyeball by the tight gripping of the lids which the sufferer is unable to prevent. While this spreading of the hot metal increases its surface, and the extent of the injury, by its allowing quicker cooling of the foreign body, it diminishes the depth to which the destruction of tissue extends. Molten metal flying some distance before striking the conjunctiva, may become cooled and hardened sufficiently to retain its shape and yet be possessed of enough heat to produce a burn capable of bringing about the most disastrous results.

The burns from scales and chips of hot iron are usually more limited in extent than from liquid metal, but often extend to as great a depth. The most common among chemic caustics is lime in some form, usually in the shape of mortar, though I have seen a number of injuries from dry pulverized lime being blown or thrown into the eye, and quite recently have seen a case where one eye was destroyed and the other seriously burned by the lime in a so-called whitewash mixture. This accident happened in one of the Union Pacific shops where three of the employees were whitewashing with a steam apparatus used for this purpose. One of the pipes burst, throwing the lime into the eyes of all the men around the machine at the time, but destroying only one eye, as above stated. The burns received by the other men, though painful, involved only the superficial layer of the cornea and were not serious.

Of the acid caustics strong sulphuric, nitric, muriatic and nitro-muriatic acids are the most common. A very small drop of either received in the conjunctival sac is capable of producing very serious consequences to both cornea and conjunctiva, before it loses its destructive power from dilution by mixing with the fluids of the conjunctival sac.

Powder in all of its forms, from the common black gunpowder to the most powerful nitros, are used in different ways by the men in the employ of the railroads, and accidents of all kinds arise from the careless handling of them. Burns from this cause range all the way from the slightest injury of the conjunctiva or cornea to the complete destruction of both these membranes.

Whatever the agent in the case may be, the amount of damage done and the results to be expected to follow will depend upon the location, extent of surface over which, and the depth to which the destructive process has extended. If the injury implicates the cornea the damage to vision will depend upon the depth and location of the burn, as if it extends deeper than the epithelial layer a scar is sure to be left whatever the treatment may be. If the injury be small and situated in the center of the cornea great damage to vision will be done, and if of large size—involving all or nearly all of the surface of the cornea—the vision will not

only be lost but the extent of the scar will preclude its restoration afterward by any operation. The burns situated in the conjunctiva are not of so much importance, if the destruction be confined to either the ocular or palpebral portion alone, but as this rarely happens where the wound is at all extensive, we usually have to deal with two raw surfaces constantly in apposition. The result of the healing process in these cases is the more or less close and extensive union of the lid and eyeball, and in some cases the union is so extensive as to entirely destroy the conjunctival sac.

From this hasty review of the cause, effects and final results of these injuries, it becomes apparent that a rational treatment, to meet all conditions, should be divided into three stages; the care of the injury itself, the management of the healing process, and operations for the correction of bad results. The first would include the time from the receipt of the injury through the first few days following, until the dead tissue has all separated and sloughed away. The second stage would extend from the end of the first period to the point where the healing process has been entirely completed, and the third and last would be after the completion of the second stage when the skill of the surgeon may be called upon to remove or rectify the results of the injury, or of the healing process, or of both.

The treatment in the first stage will include the checking or relieving the pain, the removal of the foreign substance, and the cleansing and dressing of the injured parts.

Relieving the pain is purposely put before the removal of the cause in these cases, for the reason that it is almost impossible to even examine a patient suffering from these injuries, let alone the removal of foreign material from their eyes, before the pain is relieved. With many patients, and in the less severe cases, cocaine applied locally will be found a very effective remedy in relieving the pain, so that the further steps of treatment in the first stage can be proceeded with without hindrance, but in severe cases and with the more timid patients a general anesthetic, as chloroform or ether, will be found necessary. While under the influence of the anesthetic the injured parts should be carefully examined and everything of a foreign nature removed. If the burn be caused by any of the metals, or lime, all small particles should be carefully sought out and removed, and this is sometimes a very slow and tedious process where many small particles are embedded in the substance of the conjunctiva or cornea or both, but this part of the work must be thoroughly done, for the minutest portion of foreign substance left will certainly act as an irritant and increase the amount of inflammation and ulceration to follow. After every particle that can be found has been removed, the conjunctival sac should be freely washed out with some aseptic fluid, one of the best of which is sterilized water, either pure or with the addition of boric acid. When the cause of the burn is some liquid substance, thorough washing will be sufficient unless the agent be an acid and the patient seen very soon after, or at the time of the injury, when a weak alkali added to the water would no doubt be of some service in neutralizing the acid remaining in the conjunctival sac.

In dressing these wounds, after cleansing, the chief principle observed in the dressing of burns in other parts of the body should be observed; that is, the exclusion of air. Burns in this locality are very favorably situated for the carrying out of this principle, as the mere closing of the lids does this pretty effectually. Although the lids are of service in this respect they are capable of causing much damage in other ways. The continual rubbing of the palpebral conjunctiva on the cornea or the ocular conjunctiva, in winking, would seriously interfere with the healing of any broken surface on either. To obviate this difficulty, as well as to add further protection from air, a light compress of borated cotton and a gauze bandage should be applied. Before applying the bandage a little vaselin, olive or castor oil, should be dropped into the conjunctival sac to act as a lubricant, and also to separate the broken surfaces to a greater or less extent. Of these agents, I find the castor oil is the most bland and the least easily absorbed.

If the burn is extensive and the cornea involved, atropia should be added to the oil, both for its effect on the cornea and to prevent or subdue the iritis which is pretty sure to follow any severe burn of the cornea. The dressing can be removed and the drops repeated every four or five hours as needed, and at such times all pus and sloughs should be wiped away with pledgets of cotton soaked in saturated solution of boric acid. For the first forty-eight hours after the receipt of the injury, I have found a small bag of broken ice applied over the bandage, the greater part of the time, to be

of the greatest service in limiting both the swelling and the inflammation. To control the pain following these burns, a hypodermic injection of morphia or morphia by the mouth should be given. No reliance can be put on cocaine as recommended by some writers for this purpose. The careful cleansing with aseptic lotions, and the complete rest procured for both the lids and the eye itself by the use of the bandage, and the atropia and application of the ice-bag, comprise about all that can be done to check the inflammation, limit the ulcerative process so liable to follow or attend the sloughing of the dead portions of cornea or conjunctiva, and hasten the beginning of the second or healing stage.

With the beginning of the second stage the treatment changes to a considerable extent, as the objects to be attained here are very different from those in the first stage. Here we desire to hasten the healing process, check further destruction of tissue by ulceration and prevent as far as possible the formation of adhesions between the lids and eyeball. The use of the bandage should be continued, as well as the oil and the careful cleansing of the granulating surfaces. Just how much can be done to prevent the formation of adhesions is something of a problem.

My own experience in these cases, and I have seen many of them, has taught me to believe that little good is accomplished by any of the methods given in the text-books to prevent this dreaded result, except in the cases where the burned surface is not large or is situated near the margin of the lids. In these mild cases the breaking up of the adhesions by passing a strabismus hook around them and forcibly separating the adhering surfaces at each dressing has, in several cases that have come under my care been of great benefit, in some cases preventing union entirely and in others making the uniting band so small as to be very easily removed by operative procedures afterward. Of late, however, I have adopted a plan that in my hands brings about much quicker and better results than any that I have seen advocated. It may have been used by many others before me, but if so I have failed to find any mention of it in print. This plan consists in treating the burns in the ocular conjunctiva, (at the end of the first stage) the same as any other wound causing a solution of continuity of that membrane would be treated, that is, separating the conjunctiva from the sclera round about the burn to an extent sufficient to allow of the bringing of the edges of the conjunctiva together and uniting them with stitches. The unbroken surface presented by the shifted portion of the ocular conjunctiva prevents any union between that and the denuded surface of the palpebral portion of that membrane, which is then left to itself to heal by granulation. The loose connection between the conjunctiva and sclera allows of very great displacement of this membrane and one is often astonished at the size of the wounds that can be covered in the way above mentioned. Time and trouble are saved to both patient and surgeon, and fully as good if not better results obtained than would be by following the old rule of letting the adhesions form and then removing them by plastic operations.

In cases where the amount of conjunctival tissue destroyed is so great that the above method can not be used, I have for some time been in the habit of employing skin grafts to cover the denuded surface not, as suggested by text-books, at the end of the healing stage, but at the beginning. As soon as the dead tissue is cleared away, the conjunctival sac is thoroughly cleansed with warm boric acid solution and Thiersch's flaps or grafts applied to the raw surface. The compress and bandage are then re-applied and left undisturbed for twenty-four hours when the dressing is carefully removed and the lids separated sufficiently to allow the escape of whatever fluid may have collected in the conjunctival sac.

As every one knows who has tried skin grafting in this region, the chief cause of failure is in the amount of moisture or secretion that collects in the conjunctival sac. This is less at the beginning of the second stage than later, when the denuded surface is covered with more luxuriant granulations, hence the propriety of using the grafts as early as possible.

If the first set of grafts die wholly, or in part, another attempt should be made with as little delay as possible. By freshening the granulating surface, (by scraping) these attempts can be repeated until success crowns the effort, or the healing process shuts out any further opportunity.

In many of these cases the grafting will prove successful and the formation of adhesions be prevented, but in those cases where this part of the treatment proves a failure it

leaves the conditions no worse for the third stage than they would otherwise have been.

The treatment in the third or last stage aims at the correction of the defects produced by the injury or the healing process following. These conditions may be such as to call for an enucleation to stop the constant irritation caused by adhesions between lids and eyeball, or to prevent sympathetic trouble where the burn has involved the deeper structures of the eye; an amputation of the anterior part of the globe so that a shell can be worn to cover up unsightly scars; an iridectomy to improve vision; a plastic operation to remove adhesion between eyeball and lids or between the lids themselves; or for an operation to correct an entropion. In these cases each individual one is a study in itself and no certain rules can be laid down for their management. The skillful operator can here have his ability and patience tried to the utmost, and then after bringing all known resources into use may still score a failure. But with patience and perseverance in the performance of whatever operation the particular case in hand may call for, the results in many cases are sufficiently good to satisfy both the patient and surgeon.

Even if the vision of the injured eye is lost, many dollars can be saved the railroad company, and the patient himself be much better satisfied, if a fair appearing result can be obtained. Nothing enlists the sympathy of the jury more, and consequently increases the amount of damages awarded, than an unsightly appearance presented by the complainant. For the benefit of both the patient and the company that foots the bill, as well as for his own reputation, the railway surgeon should treat these cases with patience and perseverance, even when no benefit except from a cosmetic point of view can be expected.

#### DISCUSSION.

DR. PECK—In connection with this paper I desire to report a case which was interesting to me, and one which I consider unique. The case was that of a miner who was standing directly in front of an exploded dynamite charge, and received the full force of the explosion in his face and upper extremities. Both hands were burnt off to the wrists, and there were serious burns on the face, head and eyes. As a result of the burns of the cornea, there was extensive sloughing of both corneæ and in one of them there was perforation with disorganization and extrusion of the lens and escape of both aqueous and vitreous, so that when I dressed his eyes one day, I found the entire anterior segment of the eyeball inverted in a conical or funnel shape. To my surprise, after a few days the perforating ulcer healed, the contents of the eyeball filled out again to its normal shape or nearly so, and the man had perception of light with that eye.

DR. HARNDEN—I have received a good deal of comfort from this paper, for the reason that some years ago in a plastic operation of the face for a burn, there was cicatricial contraction, and I adopted a measure for which I received a great amount of censure from some of my confrères. I stitched the lids of the eye together, and I stitched the upper lip down to the chin, drawing them down by sutures, and to my surprise there was cicatrization. I did a plastic operation which healed without the usual contraction, but I made incisions, separated and dissected out the tissues, leaving a pedicle, and the sutures held the lid which had been drawn down to an unsightly condition, and the upper lip having broadened out to the margin of the ala of the nose, great deformity was prevented. The man was a banker, and with the exception of a false mustache which he has to wear on that side to match the other side, you would scarcely notice that he had been so seriously burned. Compared with the deformity he had, it was a great improvement. I was blamed for doing this operation, as it was considered by some an unprofessional act.

(To be continued.)

**The Forty-sixth Annual Session** of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

### Louisville Academy of Medicine.

The regular meeting of the Academy was held Monday evening, March 4, Dr. W. L. Rodman in the chair.

DR. I. N. BLOOM—I wish to report three cases of interest. A gentleman was sent me by an oculist three months ago with request to examine him for suspected syphilis. There was an ulceration on one tonsil, which had not progressed for four weeks, and the examination was requested with the hope that I could elicit symptoms which would show the ulcer to be the result of secondary syphilis. On stripping the patient nothing was found, and I telephoned that I could find nothing indicative of syphilis. The history was perfect; he stated that three months had elapsed between the last intercourse and the appearance of the trouble. The oculist was satisfied with the examination, and later discharged him. I examined again in a week with negative result.

This gentleman went to Philadelphia, saw a throat specialist and his diagnosis was chancre of the tonsils. On last Friday another oculist was in my office in search of some literature on chancre of the tonsil. I told him of the case I had seen in my practice four days before, and at that time a physician's card was on my table, who had called to consult me, but whom I had not seen on account of illness. This physician had a chancre of his tonsil. The oculist had not left my office more than an hour when the first patient returned and detailed the history of the development of the chancre in Philadelphia. A general outbreak occurred; there was a macular exanthem and general glandular enlargement, but when I examined him there was, except for slight cervical enlargement, no enlargement of the glands.

I was consulted by an actor who had a macular eruption and a chancre of the tonsil. He had a maculo-papular syphilide. In these cases the cause of the trouble was looked for. In women the bestial habit is the most common cause.

The gentleman who went to Philadelphia is entirely reputable, and the only tracable cause is from smoking a cigar or pipe, or drinking from an infected glass.

The possible cause in the actor, which, however, is of little scientific value, is given by him as follows: In his part in the play he impersonates a tramp, and steals a cigar from another actor and smokes it. Now the actor who first smoked the cigar had lost his hair and there were sores on his head. Actors are a class of people who are well versed in the common symptoms of these troubles. I merely offer this as a possible source of infection. The statistics which I looked up for the physician who came to me in quest of them, I remember generally without remembering them in detail, but I know chancre of the tonsil is sufficiently rare for me to report these cases which I saw in so short a time.

DR. LOUIS FRANK—As to the possibilities of infection I saw one of these cases, that of the physician, and am absolutely sure that his word can be relied upon. There is no possible way that it could be contracted from a prostitute. He practices in the country and knows of but one case of syphilis in the surrounding country and he had not seen that one for some time. The possibility is that the infection occurred from a cigar. The chancre had existed for three weeks before coming to the city. The glandular enlargement was considerable.

DR. WATHEN—I would like to ask Dr. Bloom if he can positively diagnose a primary from a secondary sore when it is situated on the tonsil.

DA. BLOOM—I failed utterly in the first case mentioned; the oculist who saw him first tried to establish a past syphilis with secondary development on the tonsil. The results show that it was a primary lesion. The young man had positively no sore on his body before going to Philadelphia.

DR. FRANK—I would further state that the doctor whose case has been reported, was seen by six and possibly seven physicians, and without asking a single question the diagnosis was made.

DR. BLOOM—But in the case alluded to there was present the secondary eruption which assisted in the diagnosis.

DR. LOUIS FRANK—I wish to report a case which shows the difficulty to be met with in the diagnosis of appendicitis, in the person of a patient at the City Hospital a week ago. The patient was admitted two or three days previously in a critical condition, with a temperature of 103 degrees, and the diagnosis was made by the resident staff, of appendicitis. When admitted to the medical ward she had a rapid pulse,

and a temperature of 103 degrees, distension, and dullness over the right iliac fossa. She denied uterine or venereal disease. When first seen she was in a condition of shock, her abdomen was distended, due to rupture of something in the abdominal cavity. She rallied somewhat under treatment and an operation was done. A median incision was made, and the belly was filled with pus, fully two quarts, which was most abundant in the pelvic cavity,—especially in the right iliac fossa, which pointed to a rupture having taken place here. The colon was bound down by a mass of adhesions. The pain had radiated from the right hip to the umbilicus. (This should have been mentioned earlier.) She died fourteen hours after the operation. At the autopsy the condition was found to be a ruptured tubo-ovarian abscess, at the junction of the tube and uterus. Both tubes were filled with pus, and the adhesions were not very dense. There was not very much pus in the uterus. Before operation the diagnosis of some pelvic trouble was made out by examination. There was present on the posterior vaginal wall a large chancroidal ulcer. Cultures made from the pus in the abdominal, pelvic and uterine cavities were found to contain the staphylococcus pyogenes aureus.

DR. McDERMOTT—The absence of pain in the case reported recalls a case of appendicitis which occurred in my practice. The patient, a robust man, was sick three or four days, and the physician, temporarily in attendance, had thought it a case of pyelitis or typhoid fever. I found a tumor in the region of the appendix and thought there was appendicitis. Dr. Roberts was called in consultation. The patient had had malaise, chills and a fever of 100 degrees. When I saw him his pulse was 110, his features composed; I prescribed tablets of morphia 1-6 grain with 1-150 of atropia, and only one was taken. He lay with his limbs flexed, as these cases generally do. He died in five days, having had a comfortable night before he died. This case staggers me, and I feel more like advocating operative procedures in the future. The autopsy showed pus in profusion but no general peritonitis; there was sepsis without pain or rigors. In all the other cases I have seen, the pain has been one of the most prominent landmarks; and the tumor has been well marked. In this case the appendix had sloughed off and could not be found. Operation had been considered each day but the condition did not seem to warrant it, as all indications pointed to a rupture in the bowel.

DR. FRANK—I would add that in the case in which I performed necropsy, the head of the colon was found displaced higher up than the umbilicus, the appendix up and behind, embedded in adhesions, was between one and two inches long.

DR. WATHEN—On several occasions I have protested against indiscriminate operations. I have been considered, from my reported discussions and from my writings, a conservative surgeon. The neglect and delay in operating upon the two reported cases indicates that doctors are sometimes too slow in deciding that an operation should be done. In Dr. Frank's case, if the patient had been examined when the pelvic symptoms first presented themselves, the pus tubes would have been detected, the operation for their removal done, and the woman might have recovered. She was not referred to the abdominal surgeon; she went on in ignorance of her condition until too late for relief. Dr. McDermott's case, to my mind, presented subjective and objective symptoms which suggested laparotomy, and had it been done soon after the tumor was noticed, it probably would have been successful. There is no doubt that too much operating is being done for appendicitis, and there are cases not operated on which should be. Studying the cases from the standpoint of the radical who is always ready to operate, and from the conservative, who perhaps waits too long, the happy medium is the correct one. The physician who operates on every case, and the one who never operates should be criticised. In all cases where there are symptoms indicating appendicitis, a consultation should be had with one who is doing this work. When no tumor is detected it is difficult oftentimes to make a diagnosis. When a tumor is outlined in the region of the appendix, occurring with a rapid pulse and temperature between 103 and 104, an operation should be done and the appendix or accumulation of pus evacuated, but many cases should be operated on even when there is no tumor.

DR. H. M. GOODMAN—I have heard many discussions on both sides of this subject, but can not get any clear indications as to the time operative procedures are demanded. Dr. Wathen, speaking of the operation being indicated when there is a tumor, recalls to my mind the case of a young lady—about two years ago,—which occurred soon after a case I

had in which Dr. Vance was associated with me, and in which the appendix sloughed off and an abscess formed; there was an opening in his back, abscess discharged, and the man recovered. The young lady's history is as follows: It was a sudden attack with pain over the appendicular region, and a fever of 100 to 101 degrees. Examination showed that about the region of the appendix there was a line of marked tenderness, the tumor being the size of two fists. I strongly advised an operation, but the family protested; medical treatment consisting of salines and sufficient opium to control pain, diet and frequent poultices, was carried out. In thirteen days an irritative diarrhea developed, which was due to the pus discharging in the bowel. The important point is, When do these cases cease to be medical and when do they become surgical? We may represent the case as cured by operation, but it perhaps would have gotten well without it.

DR. J. L. HOWARD—It is my opinion there is not enough operating done in appendicitis. Whenever the diagnosis is made the operation should be done. I know that if I had an attack of even catarrhal appendicitis I would have the appendix removed; there is no harm done, the operation is simple and almost devoid of danger; but if the surgeon is not called in until the patient is in collapse we do an injury to the good name of surgery by operating then, and run the risk of lowering our statistics.

DR. WM. BAILEY—I have said so much on this subject already that I hardly know what to say. Each time that I see cases I am in dread that they will die without a surgeon, yet many get well without a surgeon. I confess I do not know what to do. In the large majority of the cases which we see and in which the diagnosis is made, a tumor shows. But I do not want to say anything more about when they are surgical and when medical. I do not know.

DR. J. B. BULLITT—I am not quite so modest as Dr. Bailey, for I do want to say something on the subject under discussion. Fowler, in his excellent monograph on this subject, says that in the majority of cases in which a surgeon is *prescribed*, the surgeon labors under a disadvantage by being called too late. He should be called early and watch the progress of the case. There should be no question as to when the trouble ceases to be medical; it is always surgical. There is no such thing as a medical case of appendicitis. Oftentimes when the surgeon casts about in his own mind as to when a case should be operated on he is at sea; but each case should be one unto itself. The most dangerous are those cases with a falling temperature and a high pulse rate.

DR. W. F. BOGGESS—The general practitioner seems to be in the minority here to-night. I, for one, am not a believer in indiscriminate operations upon cases of appendicitis. As I sat here this evening, I could recall nine cases of appendicitis occurring in my practice; six cases were not operated on and got well, three cases were operated on and of these three, two died. One of the cases was a young man of 20 years. There was a tumor present the size of a goose egg. He had a septic tongue, temperature of 104 degrees, pulse 140, and I asked Dr. Dugan to see him with me. It was then late and he made arrangements to operate in the morning. The next morning the temperature was 100 degrees, pulse 96, the tumor gone, and the pus discharging through the bowel. There is too much operating on appendicitis, and I do not agree with the statement made that cases should be operated on as soon as diagnosed. And I believe that there were fewer cases long ago, who died from peritonitis and perityphlitis than die now from appendicitis, even though operated upon.

DR. VANCE—I believe that the physician can not tell, if patients get well, whether they have had appendicitis or not.

DR. SCHACHNER—All appendicitis cases are surgical, but it is impossible to lay down any certain rules as to when an operation should be done, and for this reason the surgeon should be constantly in attendance to determine the point when the operation should be done.

DR. FRANK—The general practitioner has as much right to assume that he has a case of appendicitis as the surgeon. The cases operated on are cases of recurring appendicitis, as a rule. When pus is present we should operate, not wait until it ruptures into the bowel. It is criminal to wait till this occurs. I believe, however, that appendicitis is surgical.

DR. McDERMOTT—I am sorry that I precipitated this discussion by the few remarks I made, but I merely want to say that cases of appendicitis, as a rule, are found by the doctor long before the surgeon sees them. The cases of appendicitis which occur are those which had diffuse peritonitis from the beginning.

The paper of the evening was read by DR. AUG. SCHACHNER, on "The Murphy Button; an Unsuccessful Case of Cholecystoduodenostomy."

## SOCIETY NEWS.

**The Kentucky State Medical Society** have issued the following circular:—The fortieth annual meeting of the Kentucky State Medical Society will be held in Harrodsburg, beginning Wednesday and continuing Thursday and Friday, June 12, 13 and 14, 1895. We desire a large attendance and a full program. Harrodsburg, the oldest town in the State, will not be outdone by any of her sister towns who have entertained the Society. The Committee of Arrangements will do all in their power to make the fortieth annual meeting the most popular and successful one in the history of the Society. Reduced railroad and hotel rates will be secured. We invite every member to attend, and bring with him an applicant for membership. Our location is central and easily reached by rail from all parts of the State. Address Dr. Steele Bailey, of Stanford, Ky., Permanent Secretary, for further information. E. M. WILEY, M.D., Chairman Committee of Arrangements.

**Tri-State Medical Society of Iowa, Illinois and Missouri.**—Preliminary announcement and program. The next meeting will be held in St. Louis, April 2, 3 and 4, 1895.

Officers: President, Dr. James Moores Ball, St. Louis; Senior Vice-President, Dr. Bayard Holmes, Chicago; Junior Vice-President, Dr. L. A. Malone, Jacksonville, Ill.; Treasurer, Dr. Charles S. Chase, Waterloo, Iowa; Secretary, Dr. Frank P. Norbury, Jacksonville, Ill.

Committee of Arrangements: Drs. W. B. Outten, George W. Cale, H. W. Loeb, A. J. Steele, E. H. Gregory, C. H. Hughes, J. H. McIntyre and James A. Close.

The Secretary announces the following papers:

Medical Evils, W. R. Allison, Peoria, Ill.; The Influence of Malaria in Rhinological and Laryngeal Work, J. R. Ash, Brighton, Ill.; The Open-Air Treatment of Consumption, Robert H. Babcock, Chicago; President's Address: The Anatomical Renaissance, James Moores Ball, St. Louis; Use of the Lever in Club-Foot, C. W. Barrier, St. Louis; Treatment of Trachoma and Trachoma Sequela, Charles H. Beard, Chicago; Tuberculosis of Bones, D. C. Brockman, Ottumwa, Iowa; The Uterine Sound and Curette, W. M. Catto, Decatur, Ill.; The Treatment of Functional Dyspepsia, J. M. G. Carter, Waukegan, Ill.; Address: Recent Advances in Therapeutics, David Cerna, Galveston, Texas; Food Adulteration—Its Cause and Prevention, Charles S. Chase, Waterloo, Iowa; Report of a Herniotomy, J. J. Conner, Pana, Ill.; Inflammation of the Anal Canal, George J. Cook, Indianapolis, Ind.; Diagnosis of Intra-Abdominal and Pelvic Pathologic Conditions, A. H. Cordier, Kansas City; What is Scrofula? A. C. Corr, Carlinville, Ill.; Study of a Family of Four Degenerate Children, Richard Dewey, Chicago; Injuries to the Pelvic Floor, F. B. Dorsey, Keokuk, Iowa; Pleurisy with Effusion, H. C. Eschbach, Albia, Iowa; Pathology and Treatment of Appendicitis, A. H. Ferguson, Chicago; Treatment of Stricture of the Rectum, S. G. Gant, Kansas City; Parasitic Nature of Cancer, Heneage Gibbs, Ann Arbor; Mucocoele of the Frontal Sinus, W. E. Guthrie, Bloomington, Ill.; Rabies, H. A. S. Hartley, Keokuk, Iowa; Some Forms of Mastoid Operation, R. C. Heflebower, Cincinnati; Indications for Laparotomy, W. O. Henry, Omaha, Neb.; Some Thoughts on Elimination, T. E. Holland, Hot Springs, Ark.; Osteal Tuberculosis Without Arthritis, Bayard Holmes, Chicago; The Economics and Ethics of Reproduction, W. Hutchinson, Des Moines, Iowa; Nocturnal Pollutions and Spermatorrhea, Henry Jacobson, St. Louis; When Shall We Amputate? Webb J. Kelly, Gallion, Ohio; Professor W. W. Keen, of Philadelphia, will hold a surgical clinic; Brain Tumor and its Surgical Treatment, Emory Lanphear, St. Louis; Ununited Fractures and Bone Lesions, E. R. Lewis, Kansas City; To Spray or Not to Spray, H. W. Loeb, St. Louis; Excision of the Rectum vs. Colotomy, J. M. Mathews, Louisville; Excision of the Elbow-Joint in Children, Samuel E. Milliken, New York; Address on Medi-

cine; The Relation of Infection to the Nervous System, H. N. Moyer, Chicago; Electrotherapy of Sexual Neurasthenia, F. P. Norbury, Jacksonville, Ill.; Professor Charles A. Oliver, of Philadelphia, will hold an ophthalmic clinic; Hysteria and Organic Disease of the Nervous System, Hugh T. Patrick, Chicago; Gastric Neuroses; Their Diagnosis and Treatment, H. E. Pearce, Kansas City; Puerperal Eclampsia, A. D. Price, Harrodsburg, Ky.; The Stigmata of Nervous Diseases and Their Utility in Diagnosis, John Punton, Kansas City; (a) Epilepsy—Removal of Cerebral Cyst; (b) Typhoid Ulcer, Perforation, Operation, Merrill B. Ricketts, Cincinnati; Address on Gynecology; Observations in the Peritoneum in Fifty Autopsies, F. Byron Robinson, Chicago; Ophthalmia Neonatorum, E. Orrin Sisson, Keokuk, Iowa; A Clinical Report on Thyroid Extract, Edwin Walker, Evansville, Ind.; Narcophilia, W. F. Waugh, Chicago; Treatment of Chronic Suppurative Middle Ear Disease, M. F. Weymann, St. Joseph; Tumors of the Eyeball, with Specimens, Wm. H. Wilder, Chicago; The Hysterical Element in Joint Diseases, Wm. E. Wirt, Cleveland, Ohio; Address on Surgery, John A. Wyeth, New York.

The sessions will be held in the Planters' Hotel. Reduced rates will be given on all railroads. Gentlemen should secure certificates from the local agent. An elegant banquet will be tendered the visiting doctors by the medical men of St. Louis. Remember the date, April 2, 3 and 4, 1895. Come early and stay late.

## SELECTIONS.

**Treatment of Favus With Heat.**—Culture experiments have shown that a temperature of 45 to 50 degrees destroyed favus fungus. This fact has been applied in the treatment of four cases of favus. A compress of sublimate of gauze (1-4000) was placed on the head and over this double current coils of tin tubing, through which water at about 50 degrees was continuously passed. In three cases recovery resulted in eight to fourteen days.—*Archiv. für Dermatologie u. Syphilis in Centralblatt für innere Medizin.*

**Laceration of the Liver.**—The *Province Med.*, 1894, No. 46, recounts the fall of a bricklayer from a staging 2 m. high and his striking, in the region of the liver, against the rim of a mortar bucket. After comparative recovery from the first shock, he died on the following day, after an attempt to leave the bed to go to stool. On the post-mortem an enormous laceration was found, 17 cm. long and 7 cm. deep, which had almost severed the lower portion of the right lobe.—*Centralblatt für Chirurgie.*

**Operative Removal of a Tumor from the Neck of a New-born Infant.**—An infant was brought in with severe dyspnea and cyanosis, the cause of which proved to be a large tumor which was situated on the anterior surface of the neck and which as a vast struma interfered with the air passages. The swelling, which was larger than a hen's egg, appeared hard and firm, rough and nodular, and extended from the chin even under the sternum. It was covered with integument (which was movable) fascia, and the superficial muscles of the neck, and embraced the hyoid, larynx and trachea on the anterior surface. On account of the poor prognosis that would attend a simple tracheotomy in so young a child, and because this operation could hardly be accomplished alone from the extent of the tumor, the whole mass was removed without anesthesia, yet not without considerable hemorrhage. A part of the thyroid was left. After the operation the respiration was at once free and the child cried aloud. The course of the wound was favorable. On section the tumor was shown to be solid with many small pin-head to pea-sized cysts. Under the microscope there were found in the midst of a connective tissue, vascular and rich in nuclei, solid and hollow epithelial plugs and cysts lined with cylindrical epithelium. The presence of undoubted cartilage was striking. The tumor was regarded as congenital struma. Virchow in the discussion pronounced the tumor a teratoma.—*Centralblatt für Gynecologie.*

**Therapeutics of Actinomycosis of the Skin.**—A Staub, in the

*Therapeut. Monatshefte*, October, 1893, reports the recovery of two cases of actinomycosis in which an operation was impossible. His experience with chrysarobin-resorcin, and chrysarobin-resorcin-ichthyol plasters, (with which salicylic acid was mixed), and with iodid of potash showed that actinomycotic infiltrations could be favorably influenced by anti-bacterial means. Extensive infiltrations gradually disappeared. Recent and long-standing areas showed a difference in the effect of local means, the former reacting slowly, the latter with remarkable rapidity. The thickening disappeared, and the skin became pale and healthy. For the deeper parts of the skin, scarification must precede antiseptic measures, and the same is true for recent infiltrations.—*Centralblatt für innere Medizin.*

**New Method of Staining Micro-organisms in the Blood.**—When there are few microorganisms and especially such as do not take a distinctive color by the Gram method, there is danger of concealment in masses of red blood corpuscles. The coloring matter attacks the hemoglobin; if this is removed, then the blood corpuscles remain unstained. Let a thin layer of blood on a cover-glass dry at ordinary temperature or only slightly elevated, treat for one-half to two minutes with the following:

5 per cent aqueous solution of carbolic acid . . . . .	6.
Saturated solution Na Cl . . . . .	30.
Glycerin . . . . .	30.
Filter.	

This fluid frees the hemoglobin, does not change the form of the red corpuscles and makes no deposit. Pour off, wash in distilled water and stain with carbol methyl blue to which 1 to 2 per cent. of aqueous solution of methyl violet is added. This method is also useful in demonstrating plasmodium malarie.—*Gazette Med. de Paris.*

**The Regulation of the Diet in Chronic Affections of the Heart.**—(Glax in *Internationale Klin. Rundschau.*) As far back as 1880 he had alluded to the favorable effect from strict limitation in ingestion of fluids in the treatment of chronic heart disease. Four years later, Oertel's book on the therapy of disturbances of the circulation appeared, in which, as well, deprivation of fluids was maintained. In two very instructive works on clinical medicine, Glax has summed up his experiences of many years in these two statements: The restriction of the ingestion of fluids is one of the most powerful measures in the treatment of chronic heart diseases, and alone is often sufficient to bring about compensation. In many cases, in which the strength of the heart is already compromised, its efficiency is renewed, as soon as the ingested fluids are regulated to correspond with the excretions.—*Centralblatt für innere Medizin.*

**Actinomycosis in the German Army.**—Düms in the *Deutsche militärärztl. Zeitschrift* states that only seven cases have been reported up to 1890, six in 1884-88 and one in 1888-89. Four of these were of undoubted oral origin, two appeared as inflammation of the lower jaw, and two as parotitis. All these patients became disabled for service. In the three other cases an entrance was effected in other ways, one apparently through the skin in the axilla, one by the lungs (mixed infection with tubercle), one by the abdominal cavity, breaking through into the right lung.

The writer adds three hitherto unpublished cases, one of the lungs resulting in death, two of the jaw; both recovered and remaining well until now, a lapse of three years. It is to be specially noted that in the last two cases the microscopic investigations were made by Karg, and that, in both, he found a variety different from the usual cladotrix form of Bostrom, and resembling the form described by Hesse in the *Deutsche Zeitschrift für Chirurgie*, 1890. The threads were thicker and longer; the usual culture procedures were unsuccessful. Finally, he succeeded in growing a whitish gray colony of clouded cladotrix threads on a blood-serum agar plate, which had been kept in an atmosphere of hydrogen at broad temperature. It was therefore a cladotrix form, difficult to cultivate out of a living body, and anaerobic. The successful treatment consisted in curetting the abscess, and irrigating with sublimate and boro-salicylic solutions. The relative rarity in the army is decidedly striking.—*Centralblatt für Chirurgie.*

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE . . . . . \$5.00

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
NO. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MARCH 16, 1895.

LEGIBLE HAND WRITING.

"A damn'd cramp piece of penmanship, as ever I saw in my life. I can read your print hand very well. But here there are such handles, shanks and dashes that one can scarce tell the head from the tail. . . . It's very odd I can read the outside of my letters where my own name is well enough. But when I come to open it, it's all—buz. That's hard, very hard; for the inside of the letter is always the cream of the correspondence."—*She Stoops to Conquer*.

We sincerely hope that none of our readers will regard this particular quotation as personal, but we are warned by experience that it is extremely easy to give offense where none was intended, and therefore we premise that the reflections are directed solely to those who write for the scientific press generally and for the dispensing pharmacist as a daily occupation. We sometimes imagine, as we have now and then caught a glimpse of a manuscript (in the office of some other medical journal) that we were fast returning to the customs anterior to the days of CADMUS and EUROPA, when men wrote their epistles in hieroglyphics, with thick ink.

Ideographism represents a picture of the object the idea of which is to be conveyed, or a symbol which by consent represents the object. This differs from Phonetism which seeks by arbitrary letters to represent the sounds of a spoken language, and which in conveyance of the idea leaves less to the imagination.

It is therefore somewhat in the nature of an appeal (in behalf of the management of other journals) that the ideograph be relegated to the Egyptologists along with the bones of the antediluvians who used pictures instead of writing when they wished to convey either instruction, sentiment or emotion to their fellow men. When we attempt to read an article written in hieroglyphics we are much embarrassed, for we think of many things a given

hieroglyph may represent, and if the author is a plain matter-of-fact scientist, he may become angry when he is represented in clear but modern type as saying something quite different from what he would have said, had he used the more common characters of the alphabet. A lively imagination, then, in the translation of hieroglyphs, is to be held severely in check, if either the peace of mind of the translator or the choler of the author are considered.

When the unimaginative drug clerk attempts the compounding of a prescription written in hieroglyph, there is little trouble, for as he is a man of one idea he fills the prescription on that basis, but as there is many a "mute inglorious MILTON" engaged in ordinary pursuits, so the prescription writer in hieroglyph may find to his sorrow when the medicine is delivered that he has to administer a witches' broth as hot as the good DOMINIE SAMPSON was forced to swallow from the ladle of MEG MERILLIES, or a poison as potent as those used in the days of the DE MEDICI.

Even more unfortunate are those extremely busy men who, although using the characters of the common alphabet when writing an article, forget to add a part of the letter or the last part or syllable of the word; for the hieroglyph did mean something if one only knew what it was, whereas the blank represents only vacancy—mere space—which may be filled by anything.

It is not necessary in conveyance of ideas by writing, that one be artistic, although to their credit be it said that there are many physicians whose handwriting is beautiful in its clearness, graceful curves and delicate tracery; but careful and close adherence to the accepted forms of the letters will, in the long run, be the surest way to prevent misunderstanding and accidents, and if by nature one can not acquire the necessary handicraft, he should use the typewriting machine or employ some one to use it in the translation of his manuscript.

We were moved to this excursus apart from the field of medicine, by the reception of an extremely ill-natured anonymous communication reflecting upon the manner of a foot note appended to the letter of a valued correspondent. In that foot note we pointed a moral really addressed to the whole medical division of the great Republic of Letters.

THE FIFTY-THIRD CONGRESS, THE ARMY AND  
NAVY MEDICAL SERVICES AND THE  
MARINE-HOSPITAL SERVICE.

The Medical Department of the Army is in an efficient condition. Its officers have the rank, pay and emoluments of other officers of like grade. They exercise command in their hospitals and over Hospital Corps detachments, and have control of their medical and hospital supplies. The Department asked for nothing from the Fifty-third Congress but to have money appropriated for its current expenses. Its

estimates, however, were pared down considerably in both years. Instead of \$185,000 estimated for the year ending June 30, 1895, and \$175,000 for the following year, the appropriation bills carried only \$160,000 in both instances. The estimate of \$10,000 for the Library was cut to \$8,000; but the appropriations for the publication of the Index Catalogue and for the Army Medical Museum were approved without reduction.

In the first session a bill was introduced which would have seriously crippled the Corps by reducing its number in those grades which are the rewards for long and faithful service; but as passed and approved, the bill merely prevented the appointment of young men to fill vacancies until the number of assistant surgeons became reduced from 125 to 110. This reduction was felt the less on account of the abandonment shortly afterward of nine or ten military posts; but notwithstanding this it is not unlikely that certain Army Medical officers failed to get a leave of absence this year for want of some one to take their place, and that some detachments may have to go into the field during the coming summer without competent medical attendance. The number of assistant surgeons at present on the roll is 115, so that 6 vacancies will have to occur before any new appointment can be made.

The amount, \$60,000, estimated for the annual needs of the Medical Department of the Navy, was duly appropriated; but outside of this our naval confrères have to be thankful to Congress less for what it did than for what it did not do. A bill to reorganize and increase the efficiency of the personnel of the Navy and Marine Corps was reported from the Committee on Naval Affairs with a recommendation for its adoption; but it did not get beyond this stage of its existence. This bill was intended to overcome a stasis in promotion from which the Navy has suffered more or less since the war, and to place in positions of responsibility and command, officers of the line who would otherwise have to pass the best years of their active service as subordinates. To accomplish this it was proposed to sacrifice the interests not only of the Medical and other staff corps, but even of many line officers, particularly those who saw service during the war and who now stand between the younger men and the coveted rank and position. To judge from the language of the Naval Committee's report the bill ought to have been favored by every medical officer in the service: "Comparing the present status of the Naval Medical Corps with that proposed by the bill it will be seen that the titles have been changed substantially as asked for; that positive rank has been given, and that a considerable number of officers have been given an advance in rank." Yet singularly enough the friends of the Medical Department were unanimous in their opposition to its passage, and in sym-

pathy with their wishes this JOURNAL fought the bill to the best of its ability. The bill, however, is dead for the time being, so that it is unnecessary to dwell further on the injustice of many of its provisions.

The status of our Naval Medical Department, compared with that of the British service or with that of our own Army, is such as to cause depression of spirit in those who belong to it. When they entered in their youth they were encouraged to face existing conditions by the hope that the evolutionary processes of the age would speedily effect a satisfactory reorganization of the Corps. Such a reorganization is what the Department needs to give energy to its present membership and enable it to fill its vacancies with the highest grade of medical graduates. While the competition for place in the Army is considerable, the Navy has not been able for many years to fill its vacancies, nor will it be able to do this until a bill has been passed removing the objectionable features of its medical service. Few graduates of medicine competent to pass the Examining Boards would elect to enter the Navy with the rank of ensign or second lieutenant and a bunk in the steerage for three years, when they can enter the Army as a first lieutenant and have selection of quarters over all officers junior to them in rank. Again, the rank of each naval medical officer should be determined by his position in his own corps and not be dependent as now, on that of his co-mate in the line. The framers of the existing law appear to have considered that it would be disastrous to naval efficiency for any staff officer to be promoted to a higher grade until after the promotion of all those of the line having the same date of prior commission. In fact, by the present law, the line officer may be represented as saying to his medical shipmate: "If I can't be promoted, you sha'n't!" Medical officers of fifteen years' service are thus tied down to the rank of junior lieutenants, a grade through which the Army Medical officer passes in five years. Longevity pay, a 10 per cent. increase, granted to passed assistant engineers at the end of every five years, should be given also to the corresponding grade of the Medical Corps; and provision should be made for voluntary retirement at the end of thirty years of service.

It will be seen from what we have said, that the Naval Medical Corps requires much to give it a standing similar to that of other military medical services. Its friends should claim this for it. It is well for them to protect the Corps, as they have been doing lately, from harmful legislation, but they should not rest content with this. A bill to reorganize the Corps when brought before the Fifty-fourth Congress, should be supported by the influence of the whole of the medical profession.

The Marine-Hospital Service has fared well, although the appropriations are much less than the

estimates. The general expenses of the Service are met by permanent annual appropriations of so much of the tax on tonnage as may be necessary, and in consequence no specific appropriation is asked for this purpose.

The total appropriations for repairs and alterations of the hospitals amount to \$27,700, and for repairs and alterations to quarantine stations, \$15,300, and for the maintenance of the Quarantine Service, \$125,000. This amount will give an ample appropriation for the efficient conduct of the Quarantine Service.

#### BACTERIA IN WATER.

The Third Report to the English Royal Society Water Research Committee, by PROFESSORS PERCY F. FRANKLAND and H. MARSHALL WARD, has just been received. In Part I the latter scientist reports a number of experiments on the influence of light in retarding the development of *B. anthracis*. The light used was the direct solar rays, reflected light and light filtered through various media, the results showing that it is the actinic end of the spectrum which is efficient. Similar experiments manifested a well marked inhibition of growth of the bacteria of Thames water and particularly of certain of the liquefying forms in the water. To the influence of sunlight is attributed an enfeeblement of the vitality of the bacteria in the summer water. In some cases it is certain that forms obtained in August, and which afterwards turned out to be identical with forms found in the winter, at first grew so feebly that their characters on the plates led one to put them down as distinct species or varieties.

Part II of the Report is a study of the behavior of the typhoid bacillus and the *B. coli communis* in potable waters, by PROFESSOR FRANKLAND. As bearing on the longevity of these microphites, which has been stated by different observers at from five to one hundred and eighty-eight days, the experiments reported have considerable practical value. The results obtained by KRAUS in his study of Munich waters artificially infected with the bacillus of typhoid, suggested the destruction of this bacillus at the end of a few days, coincident with the extensive multiplication of the ordinary water bacteria. FRANKLAND, however, took exception to this on account of the likelihood of overlooking the presence of the typhoid bacillus when scattered among the other colonies of the plate culture; and in his own experiments he eliminated the ordinary water bacteria by the use of PARIETTI's phenol broth culture for the development of such typhoid or colon bacilli as might be present. His special tests for the differentiation of these were cultures in sterile milk and in ordinary gelatin peptone; the colon bacillus coagulates the milk and yields gas bubbles in the gelatin, while the typhoid

bacillus gives neither of these reactions. [THEOBALD SMITH's fermentation tube, which permits the evolved gas to be measured and analyzed, is a great improvement on the gelatin entangled "bubble."] Ordinary Thames water artificially infected with typhoid was still found to contain living typhoid bacilli twenty-five days after infection; thirty-four days after infection they were no longer demonstrable. These results were obtained whether the water was preserved at summer or winter temperature; but there was some evidence that on the last day of their detection the bacilli were present, either in larger numbers or in a more active state in the water maintained at the winter than in that at the summer temperature. The *B. coli communis* persisted for forty days, and probably for a much longer period as no later examination was made, and on the occasion of their last detection they did not appear to have lost any of their original vitality. The typhoid bacillus persisted longer in deep well water than in that of the Thames or Loch Katrine. The addition of salt to the water increased the multiplication of the water bacteria enormously and diminished the duration of life of the typhoid bacillus. When water sterilized by steam was infected with typhoid no multiplication of the bacilli took place. This result was obtained irrespective of the amount of organic matter naturally present in the water used for the experiment. In steam sterilized water, however, the bacilli persisted for a longer time than when the ordinary water bacteria were present; but the greater bactericidal power of unsterilized water was found from some experiments to be not apparently due to the multiplication of the water bacteria and a struggle for existence between them and the typhoid bacilli, but rather to the elaboration of products by these aquatic bacteria, and possibly also by other vegetable life present in surface waters which are inimical and prejudicial to the welfare of the typhoid bacillus. We commend this report to the Water Committee of the American Public Health Association, since the Fifty-third Congress failed to take final action on the bill to appoint a commission to investigate the subject of the pollution of rivers and other natural sources of water supply.

*We want a Department of Health to attend to the prosecution of such investigations.*

#### HYPNOTISM AND MARRIAGE.

The forensic relations of hypnotism are coming to the front very rapidly. Within a few days, word has come from a small town near Grand Rapids, Mich., that one PETER BLANKSMA was arrested for non-support of his wife, whom he had married two months before, and two days later had left her. He admitted the desertion and said "he would have left her sooner had he known that he had married her." He further averred that he had never spoken of

matrimony to the woman, had no thought of getting married and that he could not remember anything of the matter. He alleges that she always exercised great control over his mind and that he was hypnotized and made to marry.

We fear that this subject of hypnotic influence must have other important defects than simple "tone deafness" which was so characteristic of the late TRILBY O'FARRELL. He naïvely remarks that he would not have remained with this woman two days if he had known that they were married. His mind being a blank on this important subject, he was left to act as a free moral (sic) agent. But was this actually the case? Was he not actually forced to stay there against his will by the power of hypnotic suggestion? This latter hypothesis is not tenable, because he pleads total amnesia regarding the marriage, while the fact that he lived two days with the woman is quite vivid in his recollection. If one circumstance of a given abnormal psychologic state is remembered the others must be. We would rather refer this episode to the domain of "auto-suggestion." We will not, however, speculate as to their character, merely premising that they must be within the experience and the education of the individual.

In the name of all that is good, why did this woman ever allow her husband to come to a knowledge of his miserable matrimonial estate? Why did she not forever keep from him the fact that he was a benedict? For two days she kept him in profound ignorance of his unfortunate position. Surely, with her commanding powers, and the intimacy of married life she could have prolonged the suggestion that he was a single man indefinitely and then they might have lived happily ever afterward. He, in the happy thought that he was living with a woman not his wife. She, with a husband so kind and obedient that not only was her every word a law, but also a suggestion.

#### THE JOURNAL TRAIN.

The JOURNAL train will leave Chicago this year *via* the Pennsylvania route. A vestibuled train with all the modern improvements. Due notice will be given.

---

#### CORRESPONDENCE.

##### A Letter to an Aspiring "Abdominal" Surgeon.

*Dear Doctor:*—After you left, in thinking over the case, I questioned myself if I did right in encouraging you to operate, for although such cases are sometimes easy, as a rule they are complicated and difficult, and for any one to attempt such an operation who has never seen or assisted at any, is a very serious matter. To do abdominal surgery, you must prepare yourself, you must have assisted at a great many operations, to see the difficulties you will encounter and find out how to meet them. To operate on a case is a very serious matter if you are not prepared and have not

the facilities to meet emergencies. The great abdominal surgeons in this country—those who have done hundreds of cases, still go around from one city to the other to see other operators and get pointers from them. They are never satisfied with their ability; they are always on the lookout to pick up new points in the technique.

Abdominal surgeons are products of evolution; they have all been general practitioners for many years; they have especially paid attention to diagnosis. Some of them, as the result of environments, became expert obstetricians and consequently also gynecologists. Their general practice they gradually gave up; and as gynecology grew, they had finally also to give up the practice of obstetrics, and so became exclusively, gynecologists.

The gynecology of the past consisted in smearing a little iodine on the cervix and inserting a pessary for retroversion; with an occasional operation for vesico-vaginal fistula or lacerated perineum. But gynecology grew, and it was found that the tubes or ovaries were the cause of the trouble in many cases. They were removed, and the gynecologist became a pelvic surgeon.

Pelvic surgery frequently requires the repair of injured intestines and of the bladder; sometimes a mistake was made in the diagnosis and what was supposed to be a pus tube, was found to be a diseased appendix, or the enlarged spleen was mistaken for a fibroid tumor, and the pelvic surgeons found themselves obliged to operate on all the abdominal organs and thus they became abdominal surgeons.

Another class of general physicians seem to have a peculiar gift in treating fractures and dislocations, and in operating, and thus became general surgeons; as general surgeons they also had to remove tumors of various kinds; they had to open the abdominal cavity, treat diseases of the liver and kidney, and operate for hernia and so became familiar with abdominal surgery. They gradually gave up general practice, some of them even gave up general surgery and became abdominal surgeons, pure and simple. Thus, my dear doctor, you see that the so-called abdominal surgeons have gradually been evolved from the general practitioner. They have tried to master all the branches of medical science; they have developed medical skill in every direction; they have studied pathology and etiology; they have kept abreast with the wonderful progress made in bacteriology, and with our improved knowledge of the diseases of the nervous system and of reflex neurosis.

In short, they have tried to master a fair knowledge of the general practice of medicine and they tried to become expert in the technique of operations, so that they could diagnose a case which required operation promptly, and make few mistakes, and if the patient required an operation they could perform it quickly and safely.

Then for you to attempt such an operation without any training whatever, and without even knowing what the trouble really is, I would consider reckless; in fact, it would be unjust to the patient. You have no right to trifle with human life in that manner, no matter if the patient trusts you and the family will not blame you if she dies. The question before you is, Are you doing the *highest ultimate good to the patient as you have sworn to do by the Hippocratic oath*? Do you think that you can operate as well as some other persons who have had more experience? I think you would not say, yes. You must admit that such a patient has 500 per cent. more chance to live if she goes to a hospital and is operated on by an experienced man, than if you operate on her without the facilities that a hospital offers. This is simply the moral aspect of the case. When it comes to the low, common, commercial view, it is a very poor investment on your side. In your letter, which I have just received, you say that your future success depends upon the result of this

operation. You certainly risk a great deal on the cast of the die. You know that this case may do you a great deal of harm; your competitors will call you reckless, for there are always plenty around who will do backbiting as you well know, so that you run a very great risk, as you say, of injuring your reputation. Now what do you gain? Why, absolutely nothing. The patient probably can not pay a cent, and if you should be successful and the patient lives, who will know anything about it? Who will ever hear about it? The few people with whom the woman is acquainted do not amount to anything. Your competitors will belittle the operation if she gets well, and say it did not amount to much. You will neither pick up any new business nor get any new cases, because they are few and far between. If the woman gets well, few will know about it; if she dies, everybody will hear of her death; they will inquire about the cause and find out all about it, and that certainly will not help your reputation; really the game is not worth the powder. Such isolated cases as a general practitioner gets of this kind do him absolutely no good. They waste more money in buying instruments than they get for the case.

If you want to become an abdominal surgeon, come down for a couple of weeks and I will show you all the cases I can. Go to Philadelphia and New York and see the great operators and assist them. I will be glad to help you and give you letters to these men. Then after having prepared yourself for three or four months, by seeing many cases and assisting at them, you can tackle them yourself and may become as expert as any one, but now, without preliminary training, I would advise you to keep your hands off, for you will do yourself no good and only injure your reputation, and you trifle with human life.

How much better it is to establish a reputation of being careful and conscientious. How much better you stand in a community when you admit that you do not know everything, but that there are special, rare and complicated cases which can only be handled properly by those who devote themselves exclusively to these kind of cases. Such honest statements never hurt one in a community; they rather raise you in the estimation of people. You establish a reputation for honesty and carefulness, which is so desirable. As I have plenty of cases and do not want your case, I thought that it would come in good grace from me to give you this lecture, especially as I would like to see you get along and would not like to see you do things which will hinder your further progress.

Hoping that this will be received in the same kind spirit with which it is offered, and to hear from you again, I remain,  
Yours truly, J. H. CARSTENS, M.D.

### Retinal Images in Oblique Astigmatism.

NASHVILLE, TENN., March, 1895.

To the Editor:—In your issue of February 23, on page 280, I found the following report of some remarks made in the Chicago Ophthalmological Society, by Dr. F. C. Hotz: "Dr. Hotz then spoke about the theory of the symmetric action of the oblique muscles in oblique astigmatism, so persistently advocated by Dr. Savage. He showed that Dr. Savage has given no proof of the existence of such action of the muscles. Dr. Hotz has never been able to find such action in any case of oblique astigmatism and denied that the supposed action would benefit binocular vision. He further proved by demonstrations that oblique astigmatism does not cause obliquity of the retinal images and showed that the laws of physiologic optics do not sustain such doctrine. [Italics mine.] The theory is based on false premises and wholly untenable."

In commenting on the above, allow me to say, first, that I

was unwilling to do Dr. Hotz an injustice, and therefore wrote him asking if he had been correctly quoted, calling his attention specially to that part of the report which I have italicized. By return mail I received this reply: "The report you referred to in your letter of the 25th is as correct as a brief synopsis of a paper can be." I expected him to confess that he did not believe in my theory of symmetric action of the oblique muscles, but I was greatly astonished that he should say that he was correctly reported as to the non-obliquity of retinal images in oblique astigmatism. This obliquity of retinal images was demonstrated as long ago as 1889 by Dr. J. A. Lippincott, who published the results of his studies in the March, 1889, issue of the *Archives of Ophthalmology*, in which he had cuts, demonstrating his views.

Let Dr. Hotz take any case of astigmatism of more than 3 D., with the meridian of greatest curvature either vertical, horizontal or oblique, and if the patient has ordinary intelligence he can soon satisfy himself that astigmatism is not only capable of blurring, but also of distorting, an object. One eye should be excluded while the patient is asked to look at a rectangular card, two by four inches, held vertically immediately in front of the patient, at the reading distance. As the card is revolved on a pin piercing its center, the patient should be asked its shape when at three different points. When the long sides of the card are parallel with the meridian of greatest curvature, the patient will say it is a rectangle; when these sides form an angle of  $45^\circ$  with the meridian of greatest curvature, the answer will come quickly that it is a parallelogram; again when these sides are brought to right angles with the meridian of greatest curvature, the card again is seen as a rectangle. But, possibly, Dr. Hotz is ready to say that these statements as to the distortion of the object prove nothing as to the distortion of the retinal image. Let us see: The law of projection (direction) is supreme in monocular vision, therefore the lower border of the retinal image must be in the same plane with the upper border of card, and so on for all the borders of card and image, and these planes must all cut the nodal point. Then in obedience to this law the image must be oblique when the object appears to be thus distorted.

Only one other argument as to the distortion of the retinal image in an astigmatic eye when the object is held so that its outlines are oblique to the principal meridians: All will agree that the meridian of least curvature is the line of union of the bases of the prismatic arrangement of the astigmatic cornea, and that all prisms refract light towards the base. Let us then take the right eye of a case of astigmatism, with the meridian of least curvature at  $135^\circ$ . A horizontal line held before this eye will send rays of light from its entire length into the eye, but for convenience of study we will consider only the axial rays coming from the two extremities. This ray from the left end of the line strikes above the meridian of least curvature and must be bent towards it, its subsequent course in the eye necessarily being down and out; the axial ray from the right end of the line strikes below the meridian of least curvature and must be bent towards it, the course of this ray, after refraction, being up and in. Thus it is easily shown that the image of this horizontal line must be inclined down and to the right. Because of this declination of the image, the line itself seems inclined to the same extent and in the same direction. This is one law of physiologic optics. My premises not being false, my theory may be true. My theory is not only true, but I have been able to show that it has a highly practical side. This is set forth in my paper presented at the Eighth International Congress of Ophthalmology.

The distortion in oblique astigmatism of the retinal image,

in monocular vision, is settled by the law of direction; the rotation of the eyes by the oblique muscles, in oblique astigmatism, is compelled by the more powerful law of corresponding retinal points.

In closing, allow me to make the following quotation from Dr. Maddox, of Edinburgh: "Dr. Savage has shown that a certain amount of corrective torsion, or, to substitute his own words, 'of harmonious symmetric action of the obliques, is necessary when oblique astigmatism exists in both eyes, since the retinal images of vertical objects are not themselves vertical, and that correcting cylinders which make these images vertical alter the torsional requirements. These facts may well have the practical bearing he claims for them.'"

Very truly,

G. C. SAVAGE, M.D.

### Malaria a Waterborne Disease—An Old Idea.

TECUMSEH, MICH., Feb. 9, 1895.

To the Editor:—Some discussion has lately taken place in the JOURNAL and the *Medical Record* in reference to malaria being a waterborne disease. That malarial poison is disseminated through the medium of water as well as through the atmosphere is generally mentioned by almost every writer who has given the subject attention.

Permit me to quote from a few modern authors: In Reynold's "System of Medicine," Dr. W. C. Maclean states: "That it is a common belief in India that water is capable of absorbing malaria, and that periodic fevers, dysentery, and even cholera are produced by drinking water so charged." Dr. Bristowe states in his work on "Theory and Practice of Medicine:" "That it is dangerous (according to some) to drink the water, however pure it may seem to be, which is furnished by the soil of such localities." Referring to malarious localities, Dr. Loomis, in his excellent work on "Practical Medicine" says: "The question arises, How does malarial poison gain entrance into the human body? The most reasonable view is that this is effected through the respired air. Certain facts seem to show that it may be introduced through the intestinal tract with the food and water. There seems to be scarcely a doubt but that it may be taken into the stomach with foul drinking water." In Pepper's "System of Medicine" edition 1884, Dr. Samuel M. Bemiss states in his article on malarial fevers: "That malaria is miscible with water. It is capable of being carried by currents of water through distances and periods of time altogether undetermined without losing its toxic effect or, perhaps, the faculty of reproduction. It is more than likely that this means of conveyance has effected its distribution to continents and islands too widely separated to justify a belief that it was wind-wafted. No observation need be adduced to establish the waterborne habit of the malarial poison, or the positive liability to its toxic effects when received into the stomach through this medium. These facts have been well understood from the time of Hippocrates."

Dr. W. Gilman Thompson, in the "American Text-book on the Theory and Practice of Medicine" states: "The mode of malarial infection is not definitely understood. The miasm seems to enter the system through the medium of inhalation, while at other times it apparently enters through the alimentary canal by means of contaminated drinking water, or other fluids exposed to a malarial atmosphere."

Quotations might be made from various other writers on this subject, in order to illustrate the fact which has long been known to the medical profession, that malaria is a waterborne as well as an airborne disease.

Very respectfully yours,

J. F. JENKINS, M.D.

### Injectons in Hernia.

BREWTON, ALA., March 6, 1895.

To the Editor:—Will you kindly give me the formula used for the radical cure of hernia by the injection method? Also please state whether or not you consider such injections safe, and if not, what is the special danger?

By so doing you will confer an appreciated favor. Also please refer me to any literature on the subject of which you may know.

Respectfully,

L. M. McLENDON, M.D.

ANSWER:

Fl. Ext. Querci Albæ (reduced by distillation one-half) . . . . .	64
Alcohol, 90 per cent . . . . .	16
Ether Sulph . . . . .	8
Morphiæ Sulphatis . . . . .	24
Tr. Veratri Viridis . . . . .	8

M.

Inject from 5 to 20 drops in small and recent herniæ, but 25 to 50 drops in old and larger herniæ. Heaton. See also Heaton on Cure of Rupture, Boston, 1877.

### Tetanus Toxin.

COLORADO, TEX., Feb. 8, 1895.

To the Editor:—I am preparing an article on "Tetanus" to be read at the meeting of the State Association in April. Will you do me the kindness to give me the result of treatment so far as you can, with inoculations of tetanus toxin in your city?

Very truly yours,

P. C. COLEMAN, M.D.

### Chromicizing Catgut.

MILWAUKEE, WIS., March 6, 1895.

To the Editor:—The formula for chromicizing catgut according to Lister, as quoted by you from Lucas-Championnierre, contains no chromic acid.

Yours truly,

FREDERICK SHIMONEK.

ANSWER:—We gave the original formula for carbolicized gut, but Professor Lister (*Trans. Int. Med. Cong.*, Philadelphia, 1877, p. 538) said: "I have at last made a mixture of carbolic acid, glycerin, chromic acid, spirit of wine and water, which I think will prove the very thing required;" but he did not give the exact formula. The following from Wharton will be found useful: "Soak the catgut in alcohol a short time, then place it in the following solution for forty-eight hours:

"Chromic acid . . . . .	106
Carbolic acid . . . . .	12
Alcohol . . . . .	8
Water . . . . .	80

M.

"It is then removed and placed in glass jars for use. Before using soak for thirty minutes in a 5 per cent. solution of carbolic acid."

## ASSOCIATION NEWS.

### The Baltimore Meeting—Hotel Accommodation and Rates.

The hotels named below have agreed to accept a reduction from their regular rates for accommodating the members and delegates attending the meeting of AMERICAN MEDICAL ASSOCIATION in May next. All of these houses are first class and will give satisfactory service. The capacity of each house mentioned shows the number of rooms available at the time of meeting, as estimated by the proprietor.

European Plan:—Hotel Stafford (headquarters), Washington Place, capacity 150, rooms \$1.50 to \$5 per day; Hotel Rennert, Saratoga and Liberty Streets, capacity 250, rooms \$1.50 and upward per day; Mt. Vernon Hotel, Mt

Vernon Place west, capacity 40, rooms \$1.50 per day, two persons in room \$2.50 per day; Hotel Imperial, Monument Square, capacity 100, rooms \$1 to \$1.50 per day; Hotel Studio, Charles Street and Mt. Royal Avenue, capacity 10 to 15, rooms \$1.50 per day.

*American Plan:*—Carrollton Hotel, Baltimore and Light Streets, capacity 250, \$3 to \$4 per day; Hotel Altamont Eutaw Place and Lauvale Street, capacity 50 to 100, \$2.50 per day; Hotel Albion, Cathedral and Richmond Street, capacity 40 to 60, \$2.50 to \$4 per day; Eutaw House, Baltimore and Eutaw Streets, capacity 60 to 100, \$2.50 to \$3 per day.

In addition there are a number of smaller hotels and many excellent boarding houses where accommodations can be had for from \$1 to \$2 per day. A list of these will be kept at the registration desk during the meeting.

Any one preferring the quiet, comfort and economy of a family hotel or boarding house can have the necessary accommodations reserved by making early application to the Secretary of the Committee. **GEORGE H. ROSE,**  
Secretary Committee of Arrangements.

**Section on Ophthalmology.**—Preliminary program of the Section on Ophthalmology of the AMERICAN MEDICAL ASSOCIATION for the Baltimore meeting:

1. Address of the Chairman, Edward Jackson, Denver, Colo.
2. Incipient Cataract, by A. R. Baker, Cleveland, Ohio. Discussion opened by Boerne Bettman, Chicago, Ill.
3. The Operation for Secondary Cataract, by J. W. Thompson, Kansas City, Mo.
4. The Operative Treatment of Immature and Some Forms of Zonular Cataract, by J. E. Weeks, New York, N. Y. Discussion on Cataract opened by Boerne Bettman, Chicago, Ill.
5. Case of Congenital Ectopia Lentis with Diplopia, by F. C. Hotz, Chicago, Ill.
6. Ectopia Lentis, by F. B. Tiffany, Kansas City, Mo. Discussion on Ectopia Lentis opened by Harold Gifford, Omaha, Neb.
7. Symposium on Plastic Operations about the Eye, (a series of five minute papers): Skin Grafting on the Eyelids, by F. C. Hotz, Chicago, Ill.; The Restoration of the Eyelids with Sliding Flaps, by W. C. Tyree, Kansas City, Mo.; Practical Points in Anesthesia for Plastic Operations about the Eye, by M. W. Zimmerman, Philadelphia, Pa. Papers by Eugene Smith, Detroit, Mich., and Herbert Harlan, Baltimore, Md. Discussion opened by R. A. Reeves, Toronto, and G. C. Harlan, Philadelphia, Pa.
8. Symposium on Operations on the Ocular Muscles, (a series of five minute papers): The Indications for and the Advantages and Technique of Muscle Shortening, by G. C. Savage, Nashville, Tenn.; The Slight Effects sometimes Produced as the Results of Free Tenotomies of the Ocular Muscles for Heterophoria, by S. Theobald, Baltimore, Md.; The Technique of Tenotomy of the Ocular Muscles, by L. Connor, Detroit, Mich.; The Limitations of Tenotomy of the Ocular Muscles, by H. F. Hansell, Philadelphia, Pa. Papers will be read by Hiram Wood, Baltimore, Md., and C. H. Thomas, Philadelphia, Pa. Discussion opened by G. T. Stevens, New York, and S. D. Risley, Philadelphia.
9. Hysterical Affections of the Eye Muscles, by H. Gradle, Chicago, Ill.
10. Strabismus, by C. M. Hobby, Iowa City, Iowa.
11. Practical Points Gained in the Treatment of One Thousand Cases of Insufficiency of the Ocular Muscles, by J. W. Park, Harrisburg, Pa. Discussion opened by S. Theobald, Philadelphia, Pa.
12. A New and Almost Bloodless Enucleation Operation, by Boerne Bettman, Chicago, Ill.
13. Evisceration of the Eyeball, by L. Webster Fox, Philadelphia, Pa. Discussion opened by S. D. Risley and G. O. King, Philadelphia, Pa.
14. Histologic and Bacteriologic Notes on Some Cases of Penetrating Wounds of the Eyeball, together with Experimental Observations on certain Bacilli found in a Case of Post-operative Panophthalmitis, by G. E. de Schweinitz, Philadelphia, Pa. Discussion opened by R. E. Randolph, Baltimore, Md.
15. A Clinical Study of the Ulcerative Diseases of the Cornea, by S. D. Risley, Philadelphia, Pa. Discussion opened by C. J. Kipp, Newark, N. J.
16. The Infiltration Method of Anesthesia in Ophthalmic Practice, with Demonstration, by Harry V. Wurdemann,

Milwaukee, Wis. Discussion opened by Harry Freidenwald Baltimore, Md.

17. Report of Committee on the Scientific and Hygienic Value of Examining the Eyes in the Schools, by B. Alex. Randall, Philadelphia, Chairman, W. F. Southard, San Francisco, and others.

18. The Use of Prisms to Increase Vision in the Formation of New Maculae in Conical and Leucomatous Cornea, etc., by G. M. Gould, Philadelphia, Pa. Discussion opened by T. H. Fenton, Philadelphia, Pa.

19. The Percentage of Symmetrical and Asymmetrical Meridia of the Cornea in Astigmatic Eyes, by S. D. Risley, and J. L. Thorington, Philadelphia, Pa.

20. Two Thousand Five Hundred Cases of Ocular Headaches and the Different States of Refraction connected therewith, by W. F. Mittendorf, New York.

21. A Study of the Refraction of One Thousand Five Hundred Eyes, by H. Bert Ellis, Los Angeles, Cal.

22. Latent Astigmatism, by W. H. Starkey, Chicago. Discussion opened by W. H. Wilder, Chicago, Ill.

23. Anisometropia, by W. F. Southard, San Francisco. Discussion opened by S. D. Risley, Philadelphia, Pa.

24. Some Rare Complications of Infantile Purulent Conjunctivitis, by A. A. Hubbell, Buffalo, N. Y. Discussion opened by B. Alex. Randall, Philadelphia, Pa.

25. Retrobulbar Tumor, by S. C. Ayres, Cincinnati, Ohio. Discussion opened by J. A. White, Richmond, Va.

26. A Case of Enchondroma of the Cartilage of the Upper Lid, by P. D. Keyser, Philadelphia, Pa.

27. Extensive Changes in the Choroid with report of Cases, by J. T. Carpenter, Jr., Philadelphia, Pa.

28. Anomalies in Ophthalmic Practice, by A. C. Corr, Carlisle, Ind.

29. The Relationship Between Eye and Brain, by J. A. Lydston, Chicago, Ill.

30. Eight Years' Experience with the Surgical Treatment of Trachoma, by H. Gifford, Omaha, Neb.

31. Hemorrhages into the Retina and Vitreous in Young Persons Associated with evident Disease of the Retinal Blood Vessels; Remarks on the formation of Vessels into the Vitreous and in a Case of Emigrating Subhyaloid Hemorrhage, by Harry Friedenwald, Baltimore, Md.

32. Formalin as a Preservative Agent of Eye Specimens, by W. H. Wilder, Chicago, Ill. Discussion opened by F. C. Hotz, Chicago, Ill.

Papers will be read by C. T. Kollock, Charleston, N. C.; D. S. Reynolds, Louisville, Ky.; L. J. Lautenbach, Philadelphia, Pa.; C. A. Oliver, Philadelphia, Pa.

H. V. WURDEMANN, Secretary.

**Section on Dental and Oral Surgery.**—Dr. M. E. Fletcher Chairman; Dr. Eugene Talbot, Secretary.

Chairman's Address; Bacteriology, by S. A. Hopkins, Boston.

Adenoids, by Geo. F. Eames, Boston.

The Effect of Sterilizing Processes upon Steel Instruments, by Wm. H. Potter, Boston.

Common Ground of Medicine and Dentistry, Joseph Roach, Baltimore.

Destruction of Children's Teeth, Cause and Remedy, by J. G. Humsler, Baltimore.

The Progress of Modern Dental Practice, by A. H. Thompson, Topeka, Kan.

Suppuration of the Intermaxillary Bones with Fistulous Opening into the Nasal Cavity, Two Cases, by W. Xavier Sudduth, Minnesota. Ulceration of the Oral Cavity and its Treatment, by Dr. Genese, Baltimore.

Specific Treatment of Necrosis of the Alveoli and Maxilla with Sulphuric Acid, by W. A. Mills, Baltimore.

Diseases of the Soft Parts of the Mouth and Ill Developed Jaws, by W. S. Twilley, Baltimore.

A Presentation of Inflammation and Tumorous Growths caused by wearing Rubber Denture, by Bernhard Myer, Baltimore.

Calcification of the Teeth, by R. R. Andrews, Cambridge.

The Value of Differential Diagnosis in Dentistry, by Vida A. Latham, Chicago.

The Discovery of Anesthesia and its Outgrowth, Rapid Breathing as a Pain Obtruder in Minor Surgery and Medicine with its History and Application for Twenty Years, by W. Bonwill, Philadelphia.

**The Forty-sixth Annual Session** of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

## PUBLIC HEALTH.

**Progress of Cremation.**—In the annual report of the Cremation Society of England, it is asserted that the sentiment of the public against cremation is declining, and the success of the crematorium at Woking has been so satisfactory as to warrant the consideration of a proposal to build one near London.

**Sewerage of Constantinople.**—The Commission on the sanitation of Constantinople, appointed by the Sultan, recently held its first session, at which it was decided to construct main sewers in those parts of the city where none exist and to repair the existing sewers which, in their present condition are not only useless but a constant menace to the public health. It was also decided to take measures for the paving and repairing of the streets wherever necessary.

**The Healthiest Year.**—The remarkable healthfulness of 1894 is again shown in the registration returns for England and Wales. The death rate for these countries—16.6 in 1000—is the lowest ever recorded, being 1.5 per 1000 below the lowest previous rate, that of 1888 which was 18.1. It was also 2.6 per 1000 below the mean annual rate of the preceding ten years. On the other hand, the birth rate is also the lowest ever recorded—29.6 per 1000 of population, which is 2.0 per 1000 below the mean rate of the previous ten years. The birth rate in these countries shows an almost continuous decline for the decade—from 33.6 in 1884 to 29.6 last year.

**"Freshened" Beans.**—The Hygienic Council of Paris, having been consulted as to whether beans soaked in water to freshen them and give them the appearance of green beans were injurious to health, has reported (*Le Progres Medical*) that the radicles begin to develop by reason of this soaking and that this gives rise to different chemic substances, none of which, however, can be considered dangerous. On the other hand, a great many of these soaked beans present traces of moldiness between the cotyledons and a deep green coloration in the cotyledons themselves. Microscopic examination shows the presence on the surface of the well-known fungus *Penicillium glaucum* and of myriads of its spores in the colored spots of the cotyledons. Without pronouncing on the character of the fungus, the Council calls attention to the fact, now apparently well established, that the spores of this fungus introduced into the blood are capable of producing a skin disease. They conclude that "soaking beans produces enough alteration in their tissues to justify a prohibition of their sale."

**The "Influenza" Fad.**—Speaking of the so-called influenza epidemic in Great Britain, of which the JOURNAL has made note from time to time, a recent number of the London *Lancet* gives voice to a doubt which must have occurred very generally to the professional mind in this country. Is influenza really so prevalent as current gossip represents it to be? If by "influenza" is meant an acute febrile attack of short incubation, the onset characterized by severe muscular aching, rigor, high temperature and intense headache, with sometimes vomiting and diarrhea, these symptoms passing off in from twenty-four to thirty-six hours, leaving the patient greatly prostrated and with a troublesome cough and some bronchial catarrh—how many such cases are actually met with this season? While admitting that some sporadic cases of influenza are to be found, our cotemporary warns against the growing habit of calling every indefinite feverish attack by this name. "That it is a temptation no one will deny, especially when we consider how anxious patients are that their disease should be named and how the practitioner is apt to be looked down upon if he says he can not do so. But it must also be remembered

that influenza is a serious disease, and it is therefore unwise to call every febrile catarrhal affection by this name; for these latter, when properly treated, never leave any serious sequelæ, whereas the former complaint, even though treated with every care, may, and often does, leave a large legacy of grave evils behind it."

**Height of Buildings.**—The London Building Act which went into effect Jan. 1, 1895, fixes 24 meters as the maximum total height for dwelling houses. Dwellings in streets less than 15 meters in width can not exceed this height. The height of houses in France has been regulated by law for over a century. The ordinance of April 10, 1783, confirmed by that of 1792, fixed this at 54 feet (this, prior to the vogue of the metric system) in streets 30 feet wide, and 45 feet in those of less width. Legal restrictions have since been adopted in the principal French cities. In Paris the ordinance of July 23, 1874, fixed the maximum height of buildings at 12 meters in streets less than 7.80 meters in width. They may be 15 meters in streets 7.80 meters to 9.75 meters; 18 meters in those from 9.75 meters to 20 meters; any streets wider than this may have the buildings 20 meters high. In Lyons the highway ordinance of 1874 allows buildings to be 22 meters in height on quays and places of 50 meters in width; 20.50 meters in streets over 10 meters; 19 meters in streets over 8 meters and 18 meters in narrow streets. These measures are considered insufficient by hygienists of all countries. According to German authorities the two dimensions should be equal. This was also the rule established at the Buda-Pesth Congress, on motion of Corfield, of London. Trelat goes still further; he recommends that the width of the street be one and one-half times the height of the house. This goes too far, according to *L'Union Medicale*, as in the older cities we must be content with less spacious streets when new building lines are established on the older streets.

**Prevailing Morbidity.**—During the first part of March there is reported a decided increase of the acute lung diseases, the diarrheal diseases and—except diphtheria—of the acute infectious diseases throughout the country. There has been a recrudescence of smallpox in localities where it was sensibly diminishing during January and February; and, in the lower Mississippi valley—from St. Louis south—the disease is very generally prevalent and increasing. In the extreme south—Texas, for example—it is asserted that "the region is full of smallpox germs imported by Mexicans who were brought in to gather last year's cotton crop;" in some northern localities—Chicago, for instance—the increase is attributed to refugees fleeing from smallpox in the South, and outbreaks are traced to Hot Springs sojourners and to negro colonists from Tennessee. These pleas in extenuation and defense have little weight with the sanitarian, who points out that any well-vaccinated community may safely invite immigration from the Gaboon country itself, where smallpox is endemic and perennial.

Although influenza is increasing in frequency and fatality—as judged by the mortality returns of the large cities—it is still an insignificant factor of the prevailing morbidity in this country when compared with its newspaper ravages in the Old World. A late cable dispatch says that while London is indulging the hope that the crisis of the combined affliction imposed by influenza and inclement weather is passed, Paris, Vienna and St. Petersburg "still cry out in bitterness of spirit almost equal to the plague-stricken Egyptians." It is admitted, however, that the disease is declining, but they manage to get a grewsome satisfaction out of an apprehended outbreak of typhoid and diphtheria "owing to the long disuse of thousands of drains [sewers]" frozen up and unflushed for a month or more. The dispatch cited says that "the sanitary condition of London, which is usually the best of any great city in the world, is now extremely unsatisfactory," owing to the causes just mentioned.

**Health Reports.**—The Supervising Surgeon-General of the Marine-Hospital Service has received the following health reports:

SMALLPOX IN THE UNITED STATES.

Texas: In compliance with your request under date of March 2, which I have the honor to acknowledge, I herewith report the presence and present status of smallpox in Texas. The disease originated at Taylor, Williamson County, the first case making its appearance in a boy—the child of a restaurant keeper, about February 15. The infection was introduced by Mexican laborers, brought here for farm hands. The presence of this case was concealed from the authorities until in the pustular stage; meantime many persons had been exposed and gone on their way; hence the dissemination of the infection. It was next reported at Wortham, in Freestone County, near the line of Navarro County; and a few scattering cases at other points in the latter county. A case was also reported near Hutto, on the M., K. & T. Railway. I visited each of the infected localities upon the request of local authorities, and personally saw that all necessary steps were at once taken to prevent the spread of the disease. Three cases were reported to this office as having appeared at Fort Worth. Dr. Cunningham, the city physician, reported that he did not know the source of the infection, and that a number of transient persons had been exposed before the disease was diagnosed, and escaped the health authorities. It is unnecessary to say that each case, as developed, is promptly isolated and strictly guarded; that all persons known to have been exposed are separated and kept under observation during the period of incubation, and that disinfection and very general vaccination are practiced. I inclose a copy of a circular letter of instructions issued to local health officers, which instructions are being everywhere enforced where the disease appears. Only a few cases—two, three or four—have occurred at any one point, and they have been in the persons of those primarily exposed; *i. e.*, exposed to the first case developed from the imported infection. This constitutes the 'second crop,' and as the exposure has taken place, generally, before the presence of the disease was known, as in the first case at Taylor, or before a diagnosis had been made, it is impossible to forestall its development. Later, it is within the scope and power of sanitation to arrest further propagation. I have no fear whatever of the disease assuming anywhere the proportions of an epidemic.

(Signed)

R. M. SWEARINGEN, M.D.

March 5, 1895.

Louisiana: New Orleans, February 24 to March 2, 1 case.  
New York: Brooklyn, March 2 to 9, 1 case.  
Michigan: Three Rivers, March 1 to 7, 1 case.  
Missouri: St. Louis, March 2 to 9, 33 cases, 6 deaths.  
Pennsylvania: Philadelphia, February 24 to March 2, 19 cases.  
Wisconsin: Milwaukee, February 24 to March 2, 7 cases, 2 deaths.  
Texas: Taylor, February 15 to March 2, 1 case; Wortham, February 15 to March 2, a few cases; Fort Worth, February 15 to March 2, 3 cases.

FOREIGN.

Reports of smallpox received by the Supervising Surgeon-General Marine-Hospital Service:

Austria: Buda-Pesth, February 11 to 18, 1 case, 1 death.  
Belgium: Antwerp, February 9 to 16, 3 cases, 2 deaths.  
Bohemia: Prague, February 2 to 9, 11 cases.  
Great Britain: London, February 9 to 16, 3 cases; February 16 to 23, 1 death.  
Gibraltar, February 10 to 17, 3 cases.  
India: Calcutta, January 19 to 26, 36 deaths.  
Holland: Rotterdam, January 16 to 23, 5 cases, 1 death.  
Russia: St. Petersburg, February 2 to 26, 13 cases, 9 deaths.  
Honduras: Tegucigalpa, February 2 to 9, 1 case.  
Scotland: Glasgow, February 16 to 23, 2 deaths.

RIO DE JANEIRO.

I have the honor to transmit report for the week ended Feb. 9, 1895. In this week there were 24 deaths from *accessio pernicioso*, an increase of 4; 14 from yellow fever, an increase of 9; 3 from smallpox, and 2 from enteric fever, the same as in the week before; 1 from beriberi, a decrease of 1; 1 from diphtheria, and none from whooping cough; 4 from cholera, an increase of 3; 7 from diarrhea cholericiformis, an increase of 5; and none reported from cholera against 1 in the previous week. The total from all causes was 299, being 10 more than in the foregoing week.

While there is an increase in the number of deaths from yellow fever, it can not yet be considered epidemic or threatening, as it is almost too late in the season for it to develop to any great extent, yet all due precautions must be observed.

Cholera does not appear to be extending in the originally infected districts, though it has extended all along the Parahyba River to Campos near its mouth, presumably due to the relaxation of sanitary measures by the authorities under pressure of the press. To this same cause may be attributed the appearance of isolated cases in this town. Besides those reported as dead from cholera, twelve suspected cases were removed to the hospital in Jurijuba Bay. I have heard of no cases among the shipping, except one aboard the ship *Gentil*, which left here for Cabo Frio, sixty miles to the eastward, and put back with a case aboard which was removed and all the customary disinfections performed. Telegrams from the Platte River state that the disease is increasing there in several towns, but really no confidence can be placed in such news here.

I visited the Vaccine Institute, which is a municipal institution, and found everything in perfect order and the cleanliness is remarkable; although there are never less than three calves (2 months old) in the stables, not the slightest odor was perceptible; they furnished me with six filled Hubbard's tubes, all of which produced the typical vaccine pustules. The establishment is in a newly arranged building and wants nothing; it is creditable to its authorities.

R. CLEARY, M.D., Sanitary Inspector, M.-H. S.

Feb. 12, 1895.

CHOLERA.

India: Calcutta, January 19 to 26, 52 deaths; Madras, January 26 to February 1, 11 deaths.

Brazil: Rio de Janeiro, February 2 to 9, 12 suspected cases.

Turkey: Constantinople, January 29 to February 4, 46 cases, 22 deaths.

Austria-Hungary: Galicia, February 4 to 10, 11 cases, 7 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, February 2 to 9, 14 deaths.

The clerk of the Bridgetown (Barbadoes) Quarantine Board reports that yellow fever has been reported by arriving vessels at following places: Curacao, January 1 to 4, 3 cases, 3 deaths; Panama, January 31, sporadic cases.

Under date of February 14, the U. S. Consul at Santos, Brazil, reported that during the week ended February 9, there were twelve cases of yellow fever in that city and eight deaths from the same disease.

Under date of February 18, the U. S. Consul General at Guayaquil, Ecuador, reports three deaths from yellow fever in that city during the week ended Feb. 14, 1895.

The U. S. Consul at Vera Cruz, Mexico, reports under date of March 1, that there was one death from yellow fever in that city during the week ended Feb. 28, 1895.

NECROLOGY.

BENJAMIN BURROUGHS, M.D., of Brooklyn, N.Y., died March 7, at the age of 47 years. He was graduated in medicine at the Long Island College Hospital in 1888 and soon afterward settled in the city named. He was a member of the Kings County Medical Society, and was for a time an employee of the Health Department and in that capacity served with marked credit and efficiency. About a year ago he manifested symptoms of pulmonary tuberculosis, and from that affection died, leaving a large circle of friends to mourn his loss.

ALBERT C. HALLAM, M.D., of Brooklyn, N.Y., died Jan. 9, 1895, in his fiftieth year. He was a native of Watertown, Conn. He obtained his medical education at Yale University, graduating in 1866. He practiced in Brooklyn from the year 1867, and was a member of the local medical society for many years, and in a number of social organizations was recognized as an influential citizen. Dr. Hallam was appointed a member of the Board of Education in 1882, by Mayor Seth Low. He was Vice-President of the Bushwick Savings Bank, and was a director of the Amphion Academy Company. He was a life member of the Amphion Musical Society, and was also one of the founders of the Hanover

Club. He was a member of the Union League and of the Windsor Club. His death occurred from an attack of uremic coma due to chronic renal disease that manifested itself fully two years before. He was twice married. His widow with two daughters survive him.

**ROBERT OGDEN DuBois, M.D.**, of New York City, died March 9, in the thirty-sixth year of his age. He was born in that city of old Huguenot stock and of a family branch that has been frequently represented in medicine. He was graduated from Yale Medical Institution in 1886, and was an assistant surgeon to the Eye and Ear Infirmary, as others of his name had been before him.

**ARNOLD HALLETT, M.D.**, formerly of Brooklyn, N.Y., died at Norwalk, Conn., on the 10th inst. He was a native of St. John, N. B., having been born there nearly seventy years ago. He was for many years attached to the surgical staff of the Long Island College Hospital, and an honored member in the local medical societies. He was an alumnus of the College of Physicians and Surgeons. He early acquired a lucrative medical business, and retired several years since from active practice.

**S. VOHDEN, M.D.**, aged 69, Baltimore, Md., March 1.—**L. Burden, M.D.**, Lagrange, Ind., March 3.—**F. Harding, M.D.**, aged 33, Norwalk, Ohio, February 25.—**M. S. Butler, M.D.**, Cherokee, Iowa, March 3.—**H. Schneider, M.D.**, aged 53, Baltimore, Md., February 28.—**W. A. Stovering, M.D.**, Cleveland, Ohio, March 3.—**A. Deitrichs, M.D.**, Denver, Colo., March 8.—**A. B. Mason, M.D.**, aged 51, Wadestown, W. Va., March 4.—**B. E. Vaughan, M.D.**, aged 32, New York, N.Y., February 25.—**W. ## MISCELLANY.

**High-Priced Cod-Liver Oil.**—Another cod-liver oil famine, similar to that of eight or ten years ago, has caused a considerable raise in price with an intimation of a still further advance. The famine is attributed to the prevailing leanness of the fish during the last year or two. The increase in price already amounts to over 100 per cent. and the effect is seen in the instructions given to hospital staffs to be economical in prescribing the oil.

**Generous Donation by a Physician.**—The Ohio Wesleyan University has received a gift of \$50,000 from Dr. Charles E. Slocum, a reputable physician at Defiance, Ohio, for the purpose of enabling that institution to erect a fireproof library building. Dr. Slocum is an alumnus of the College of Physicians and Surgeons, New York, and Jefferson Medical College, also a member of the AMERICAN MEDICAL ASSOCIATION and several other national scientific bodies.

**Wounds of the Eye.**—Ottinger has collected (*La Presse Medicale Belge*) the statistics of 1,000 cases of ocular traumatism, 398 of the right and 602 of the left eye. Of these, 715 were operative wounds and 287 accidental. Among the former the right eye was involved in 272 cases and the left in 443; among the latter, the right 128 times and the left 159 times. These figures corroborate those of Cohn, showing that the left eye is more exposed than the right.

**Medical Education in New England.**—The faculty at Yale University has decided to advance the period of the regular medical course from three up to four years. A committee has been appointed to make the necessary changes and announcements. The faculty at Harvard has voted to

authorize certain approved physicians to announce their proposed instructions yearly in the medical department. These extra-mural teachers will receive this privilege upon application to a special committee, of which Dr. E. H. Bradford is chairman.

**University of Maryland.**—As an addendum to the table of medical colleges and college attendance, republished by request in the JOURNAL of the 9th inst., the University of Maryland, Faculty of Physics—J. E. Michael, A.M., M.D., Dean—reports a total attendance at the current session of 240 students; 104 first-year, 78 second-year and 58 third-year. The figures of the total are the same as for the preceding session, but there is a gain of nearly 20 per cent. in the first-year men as compared with the previous year—the classes of 1893-94 numbering 87 first-year, 83 second-year and 80 third-year students.

**Safeguarding Street Car Travel.**—The Camden, N. J., Board of Health is pushing the passage of an ordinance to compel all street, trolley and steam cars to be fumigated daily. The Brooklyn, N. Y., Board of Aldermen is considering action looking to the appointment of inspectors for every line of surface cars operated in that city, the inspectors to regulate the speed, passage of street crossings and other measures for the safety of passengers and pedestrians. During the discussion Alderman Clark, the mover of the resolution, asserted that two, three and sometimes four people a day are killed by the surface cars in Brooklyn. This, if true, is worse than the surface crossing slaughter in Chicago.

**A Surgeon Slain by a Lion.**—Surgeon E. S. McKay, of the British Navy, is reported by the *Illustrated London News* to have been slain by a lion, near Lake Nyassa, Africa. This young man was an athlete and a prize-winner in cycling circles. After taking his medical degree he went out to Africa, for three or more trips, as surgeon to steamers. In 1889 he obtained an appointment as surgeon in the Navy, serving on the SS. *Swallow* and *Herald*. He volunteered for duty in Central Africa and while there had a few days' shooting among the elephants and large game near Lake Nyassa. One day, however, he came unexpectedly on a lion and lioness, the former of which he wounded. In pursuing the animals the surgeon advanced too far. The enraged beast sprang upon him and injured him fatally. He was buried with naval honors on the shore of the lake.

**Pay-Hospital for Infectious Diseases.**—A wealthy lady residing in New York City has responded to a suggestion that room exists in that city for an institution whereat the well-to-do, so unfortunate as to contract contagious disease may receive suitable treatment, and has started a subscription fund with a check for \$25,000. The general plan of operation of the fund will imply, says the *Medical Examiner* for February, "that the hospital shall be a private hospital; that the money shall be used solely for the purpose for which it is given; no part of it to be applied to the improvement of any existing institution, and that the management shall be in the hands of the Board of Health and of a board of trustees appointed by the subscribers to the fund toward the erection of the hospital."

**Mixed Infections in Gonorrhea.**—Bordoni-Uffreduzzi reports in the *Gazette Medicale de Liege* the case of a young girl ravished by a man suffering from gonorrhea. A few days later, double pleuritis supervened, numerous joints being also involved. Gonococci were found in the pleuritic exudate and cultures by Wertheim's method showed that no other bacteria save these were present. This case adds to the mass of evidence previously accumulated which tends to negative the theory advanced by some authors that all the complications of urethritis are due to secondary infection. ## LECTURES.

### LECTURES ON INTRACRANIAL SURGERY.

#### I.—MENINGEAL HEMORRHAGE AND ITS SURGICAL TREATMENT.

BY EMORY LANPHEAR, M.D., PH.D.

ST. LOUIS, MO.

Since Macewen, in 1879, opened the skull of a boy and removed two ounces of fluid and coagulated blood from beneath the dura in the lower part of the Rolandic area, with recovery, operations for meningeal hemorrhage have been too numerous and the results too brilliant to admit of discussion of the propriety of operative procedures whenever the site of bleeding is accessible. All progressive surgeons now agree with this statement, basing their opinion upon such statistics as those of Weisemann (*Deutsche Zeitschrift für Chirurgie*, 1885) which give 147 cases treated by the expectant plan, with 131 deaths and only 16 recoveries—a mortality of more than 89 per cent.—while 110 cases subjected to operation gave 30 deaths and 80 recoveries, a reduction of the death rate to about 27 per cent. This position assumed by operative surgeons is further strengthened by the fact that not a single death has ever been recorded from the operation itself, though a few deaths have followed from the gravity of the injury.

Hemorrhages within the cranium are, in the order of their frequency, in the caudate and lenticular nuclei; in the meninges; just beneath the cortex; in the centrum ovale; in the optic thalamus; and in the pons. Those occurring in the meninges are grouped as:

1. Extradural—between the dura and the skull.
2. Subdural—beneath the dura.
3. Subarachnoidal—in the subarachnoidean space.

The first variety is always due to injury and may be either rapid or slow in development. The second class is closely allied to hematoma of the meninges (pachymeningitis interna) but it is claimed that the hemorrhage occurs before the formation of the investing membrane and is less circumscribed. In the third variety the blood may be widely disseminated; being more or less intimately mixed with the cerebrospinal fluid it is apt to gravitate toward the base and be beyond the reach of the surgeon.

The objects in view in opening the skull are:

1. Locating the point of the hemorrhage.
2. Removing the blood clot.
3. Arresting further bleeding by: *a*, location of the ruptured vessel and ligation; or *b*, the application of a tampon of iodoform gauze.
4. Drainage in cases so demanding.

The symptoms of meningeal hemorrhage differ according to the origin. When the effusion of blood is due to the rupture of a large vessel at the base of the brain, there will be intense coma with probably no other symptom; when from a smaller vessel there

may be such prodromata as giddiness, headache and vomiting, coma still being pronounced if of basal origin. As a rule it may be said that in cases of suspected meningeal hemorrhage other than at the base of the brain, convulsions rather than paralysis constitute the marked symptom. So, too, it may be broadly asserted that when symptoms of cerebral trouble of any character make their appearance some hours after an injury to the head, the probabilities are so strongly in favor of meningeal hemorrhage as to justify opening the skull at the point of injury if known—if not, then at the location of the middle meningeal artery; for a blow upon the skull may cause a laceration of some intracranial vessel giving rise to immediate symptoms of acute hemorrhage, or it may result in a slow "secondary" hemorrhage with gradual supervention of the symptoms. Illustrative of the first kind, I quote the following from my case records:

Osby S., colored, aged 35, on Dec. 1, 1891, was found unconscious upon the street at 6 P.M., and carried to his home where he was seen by Dr. E. von Quast at 10 P.M. A diagnosis of rupture of the middle meningeal artery was made and at midnight I was called to operate. The symptoms then were profound unconsciousness, frequent and severe convulsive movements of the right arm and leg, dilatation of the pupil, stertorous respiration and temperature of 102½ degrees. Examination showed no evidence of fracture nor even of bruising of the scalp. Assisted by Drs. von Quast and C. H. Adams, I opened the skull over the region of the middle meningeal artery. Upon uncovering the vessel a complete rupture of the artery was found, the spurting being resumed as soon as the bone was removed. The end was caught without difficulty, the vessel tied and a clot the size of a large orange removed. This clot was extradural. The space between the skull and the dura which had been occupied by the clot was washed out, iodoform gauze drainage inserted and the scalp sutured and dressed with sublimate gauze. After removal of the clot the brain did not return to its normal position—so an opinion was given that death would be the result inside of twelve hours. He died at 7 A.M.

The autopsy showed degeneration of the vessels probably syphilitic. Complete collapse of the ventricles had occurred from pressure of the clot and there was a very marked anemic condition of all the intracranial structures.

I am of the opinion that this man's life might have been saved had trephining been possible soon after the accident, before the clot became so large as to produce the excessive pressure upon the vital structures.

Illustrating the second class of cases, I take this record from my note book:

Tod K., aged 13 years, fell and rolled down a bluff, a distance of sixty-five feet, striking upon his head. The accident happened at 11 A.M., May 16, 1891. He was not unconscious when conveyed to his home and a physician declared his wound not a serious one, washed the lacerated scalp and applied an antiseptic dressing. At 1 P.M., the boy began to become drowsy and vomited repeatedly. At 2 P.M., I found him almost unconscious, pulse very weak, skin of a purple color and "shock" pronounced. There was a cut in the scalp about two inches long to the left of the median line, just behind the parietal eminence, but no indication of fracture. At 3 P.M., with the assistance of Dr. John Wilson, I enlarged the opening in the scalp and turned back a flap, revealing a fracture of the parietal bone, with a slight depression nearly

two inches across. The fracture had been hidden by the scalp's slipping over it and by the boggy swelling of the soft parts. A small opening was chiseled and an elevator introduced, but the depressed bone could not be thus raised, so the hole was enlarged. Much blood came away at this time, and there was considerable bulging of the brain through the opening, the protruding matter being pulseless. A sharp fragment of the vitreous plate was found projected through the membranes into the brain tissue. Upon raising the depressed bone into position and slitting the dura, a large subdural clot was readily removed, allowing the brain to resume its natural position; pulsation at once returned in it and simultaneously the purple hue of the skin began to fade. The clot came from a tear in the posterior branch of the meningeal; to prevent further mischief the vessel was tied with catgut carried around it by a curved needle. All clots and fragments having been removed, the wound was irrigated with hot water, the cut in the dura closed with fine catgut, a small strip of iodoform gauze placed next to the dura and allowed to protrude through the scalp-wound for drainage and catgut sutures introduced through the scalp; with bichlorid dressings. At 10:30 p.m. the temperature was normal, there was no pain, the patient was bright and cheerful. May 17 at 3 p.m. the condition was excellent—pulse 90, temperature  $99\frac{1}{2}$  degrees. On May 18, I removed the drainage and applied a permanent dressing of sublimate gauze, there being no indication of pus formation. Convalescence was uneventful, the wound healing by primary union and the patient being discharged May 31, entirely well. There has never been any evidence of trouble since.

As I have already stated, the symptoms following an injury may occur soon after the accident but more often appear gradually, the bleeding slowly continuing until either the tension checks it by pressure or a fatal compression is induced. Bauduy, of St. Louis, describes the latter as "progressive extradural hemorrhage," a variety that is often mistaken or escapes us; it is commonly due to a blow upon the head with a blunt instrument, like a sand-bag, or a fall upon the head. The dura may be detached from the inner surface of the cranial vault and a slow hemorrhage occur which does not necessarily come from a rupture of the meningeal vessels or even of their small branches. The bleeding has its source in the laceration of the small vessels which everywhere pass from the dura to the bone. As the blood, little by little, escapes, the dura is gradually pushed away from the bone and the collection increases in size until symptoms of compression gradually supervene; after a period of many hours the patient becomes soporose and finally comatose. It should be remembered that all this may occur without fracture or even external contusion.

The only case of this kind I have operated on is this:

Charlie S., age 10 years, was brought to my clinic Oct. 3, 1892, by Dr. A. J. Kelley, who had been consulted on account of a partial blindness, a headache and gradually increasing drowsiness of the boy. The father said the child was struck upon the right side of the head nearly three weeks before (the mother said it was only a week) with a board in the hands of a playmate; that he was unconscious for a little while and vomited, but resumed his play, complaining of nothing but the soreness of the "lump" which appeared where he was struck. For several days (exact time not obtainable) he showed no signs of trouble, but finally became indisposed and said he could not see well; a few days later occipital headache appeared and a stupor came on from which he could be aroused only with great difficulty. At the time of examination there was bilateral hemianopsia (blindness of corresponding sides of both eyes) of the left side, slight ataxic gait, sluggish pupils, and a tendency to sink into a stupor from which he could, with some effort, be aroused for a time.

There was no external evidence of injury. Recognizing the danger of delay, I operated within an hour after examination, assisted by Dr. Kelly and a student, opening the skull over the middle occipital convolutions—the point indicated by cerebral localization, and corresponding nearly

to the place designated by the parents as the spot injured. Upon removing the button, a lot of half clotted blood bulged from the opening. The quantity expelled was so great that I feared there had been an injury to and subsequent leakage from either the lateral sinus or the superior longitudinal. I therefore very cautiously removed the blood with a spoon and pieces of gauze. No source of the hemorrhage could be found, but a little oozing continued after irrigation. So I packed the wound (not very tightly) with iodoform gauze, closed the external cut except at the point of protrusion of gauze, and dressed antiseptically. There was no injury to the dura. Reaction was prompt and satisfactory. The temperature rose to 100.5 degrees on the second day but fell by the evening of the third, when the drain was removed. No more bleeding had occurred, but a few strands of catgut were inserted in the dura to continue drainage for a short time. All bad symptoms disappeared upon removal of the gauze packing. Convalescence was rapid and the boy was still in excellent health some months ago, although there is still pulsation at the point of trephining.

Diagram showing location of the clot.

This diagram represents the location of the blood, the dark area showing its approximate extent. About three tablespoonfuls of blood were removed.

Ransohoff, of Cincinnati, has noticed that in addition to these symptoms of hemorrhage there is a high specific gravity of the urine (1030 to 1040) with the presence of sugar.

In some non-traumatic cases it will be impossible to make a diagnosis between meningeal and cerebral hemorrhage, though the differentiation can sometimes be made. But even if one be certain in the diagnosis, operation is not to be made if the heart's action is much affected in its rhythm, depressed, the respiration irregular and swallowing difficult—the difficulty is probably of the subarachnoidean variety with involvement of the pons and medulla; trephining would be useless.

Small clots upon the convexity usually cause convulsive movements, but they may also produce monoplegia, amnesic or ataxic aphasia, hemianopsia, etc. in which case location of the lesion is easy, particularly if the patient be within one of the periods of life especially prone to this form of hemorrhage, viz. below 10 years or over 50 years, it being generally acknowledged that the veins as well as arteries are very liable to rupture when young children are injured in the head, while in the elderly, atheroma predisposes to the same accident. In a large proportion of cases as the cause is an injury the condition can be recognized readily.

When there is an injury the wound indicates the site for operative procedures. If there be no external guide, dependence must be placed upon localizing signs, providing they be sufficiently positive. Otherwise in suspicious cases one is justified in opening the head over the region of the middle meningeal artery which, according to Treves, crosses the anterior and inferior angle of the parietal bone at a point one and one-half inches behind the external angular process of the frontal bone and one and three-quarter inches above the zygoma. The center-pin of the trephine should be inserted one and one-half inches behind the external angular process and one inch above the zygoma. Should the hole show no hemorrhage it may be enlarged upward and backward, or a second button may be removed just below the parietal eminence, this point being over the posterior branch of the artery.

The time of selection for operation is not later than eighteen to twenty-four hours after the hemorrhage, and yet the surgeon should not hesitate to operate much later than this, since the clot may remain for months, as in the case reported by McBurney, of New York, in which he trephined four months after the injury and removed a clot which was still unabsorbed and causing trouble—securing a favorable result.

If the patient be unconscious no anesthetic is necessary. The method of opening the skull must depend upon the instruments at hand or the operator's choice between the trephine, the mallet and chisel, and the gouge and rongeurs. The clot when discovered should be removed by the fingers or forceps and the irrigator allowed to flow into the cavity for a minute or two, so that all remnants of blood may be washed out and any bleeding vessel uncovered. If a ruptured vessel be found in the dura, it must be ligated by catgut passed beneath it with a curved needle, and tied securely. If the main artery in the bony canal be the source of trouble, the bleeding may usually be controlled by punching with the sharp end of the handle of the bone forceps; in extraordinary cases it may be necessary to crush the bone upon the vessel by strong sequester forceps. Vessels in the pia and beneath, like the Sylvian, can be readily caught by passing a fine curved needle beneath, carrying a catgut ligature for tying. Not much force should be used in ligating vessels in this location for the reason that they rupture very easily under even moderate strain. When a general oozing is found, or hemorrhage from points not accessible, the only method to pursue is to pack with iodoform gauze, then close the scalp wound and apply a firm compress over all; the tampon should be removed in thirty-six to forty-eight hours.

In conclusion, I give you this summary, under the heading of

#### RULES FOR TREPHINING.

*When to Operate.*—1. An injury to the head, followed after a little time by marked cerebral symptoms, imperatively demands trephining at the point of injury if known; if not, then over the middle meningeal artery of the affected side.

2. In progressive or extradural hemorrhage—caused by a fall on the head or a blow from a dull instrument like a sand-bag—if symptoms of compression appear after many hours, or even days, there being no fracture or contusion as a guide, it is proper to open the skull over the middle meningeal

artery; if no trouble be found there, then over the posterior branch.

3. Cases of "compression" or "concussion" without localizing symptoms or external evidence of injury should be subjected to exploration if there be no return of consciousness within eighteen hours at the farthest; upon both sides if necessary.

4. Giddiness, headache and vomiting, with stupor and convulsions of one side, may be due to meningeal hemorrhage; exploration is permissible.

*When not to Operate.*—1. When the heart's action is depressed, respiration irregular and swallowing difficult, the hemorrhage is probably subarachnoid and operation can not be of benefit.

2. In cases dependent upon fracture, if blood be discharged from the mouth or ear there is basal injury and the justifiability of operation is questionable

### ORIGINAL ARTICLES.

#### SOME POINTS PERTAINING TO THE PRESENT PATHOLOGIC AND THERAPEUTIC STATUS OF DIPHTHERIA.

BY I. N. LOVE, M.D.

ST. LOUIS, MO.

It will be admitted that until recently the management of diphtheria upon the part of the medical profession as well as many other diseases, has been empirical. Since the definite cause of this disease has seemed to be established, we have been able to work more intelligently in our treatment. It must not be forgotten, however, that able men in the profession do not yet accept the germ theory of disease. Among the number so great a man as Dr. Lawson Tait affirms his disbelief. He is of the opinion that these organisms abound and multiply under two conditions or states—decomposition and disease. He thinks their presence is incident to but not causative of disease. To illustrate his idea, he presents the homely illustration of the dead animal under the mid-summer sun. The prolific development of tissue destroyers in the form of maggots from microscopic parasites does not demonstrate to him that the maggots had anything to do with the death of the animal, but that the vitality of the latter, having been reduced to zero, the maggots, germs and spores utilize the opportunity for vital development upon their own part. He with others, believes that the various organisms operating under the conditions of disease and decomposition, attempt to act as scavengers for the removal of effete matter and perverted secretions and excretions rather than as the causes of morbid conditions. Discussing this subject before the Birmingham Midland branch of the British Medical Association last October, Mr. Tait threw hot shot against the germists by citing the difference of opinion among dermatologists regarding the parasitic origin of eczema; he quotes many of their best observers who believe that it is of neurotic origin and that microbes have nothing to do with it. He aptly says that if we can not settle upon the germ as being the cause of a disease so superficial, so exposed to view, so universal and so open to study as eczema, that there are few cases where it is capable of settlement. We can many of us sympathize with Tait when he says: "I entered my college career just as the grand sweep of the cellular pathology was careering over the medical world. Everybody was mad after a new cell. Special courses and special

teachers were told off for cellular instruction. Our microscopes had got so far as to unriddle the facts of cellular construction, and therefore there must be a cellular pathology which was to explain everything. Two parties existed and they fought bitterly, the only real and permanent effect being that the unhappy student had to meet two sets of examiners and to know two sets of answers to the same questions; the one to be given as the wind blew from the east, the other as the turn of the west wind came. The cellular party apparently triumphed, but it has silently and mysteriously disappeared, so that we may ask with Hans Breitman: "Where is dad barty now?"

In his paper, Tait refers to a contribution of Dr. Leslie Roberts in a recent number of the *British Medical Journal* on the pathology of vegetable hair parasites, and remarks that it interested him greatly because it was a phase of the dermatologic investigation getting as near the laboratory flasks as seems possible. Tait makes a note of the lack of unity of opinion on the part of dermatologists, with reference to the pathology of vegetable hair parasites. He suggests that from a bacteriologic standpoint they are no further advanced than botanists were in the times of Gussieu and Linnaeus, and that the philosophical revolution affected by Darwin has not yet reached them, and refers sarcastically to the amount of drivel that is made to center around the culture tube. He very tersely says: "What should we say if an investigator provided to classify the trees in an orchard by the shape of their branches or the color displayed by their fruit?" He says logic can not change with the size of the objects or with the apparatus and manipulation. He decries the rapidly appearing successive memoirs which are self-contradictory and which are objectionable and unusual in scientific research, and suggests to us all the necessity of reserving judgment. Indeed he says, many of the opinions maintained so strongly regarding bacteria have passed into medical currency with very little inquiry on the part of those who have reached them. He says their work is carried on without regard to the first principles of Bacon and with an utter disregard to the teachings and examples of Darwin. "The very fundamental thoughts of the evolutionary school of biology are brushed aside, and the great text-book of Sachs might as well have never been written."

Tait criticises the application of Pasteur's law which he so wonderfully illustrated in the process of brewing and wine fermentation, which were of such enormous financial value to the interests involved, as not being applicable to the human body, and says that Pasteur was responsible for leading wildly astray many young doctors who had never studied Bacon and were incapable of grasping the fact that while the former might be wholly right in the brewing vat, it required a re-arrangement of the syllogisms to carry the argument to the human body. For instance, take ten thousand human bodies all perfectly alike, as far as we can see, and drop your germs of typhus about and see what will happen. The first remarkable fact to be found is that if the bodies are in Birmingham there will probably be no effect at all. If they are in Edinburgh, no effect, or very little will be seen in the new town; whereas in the old town some commotion will result and there will be about a hundred cases of typhus. These will be distributed in various centers with mathematical proportion, and probably no two cases will be exactly alike.

Clearly then, according to Bacon, the provocative cause lies not in the germs.

We can not ignore some of the bacteriologic perplexities which confront us, however loyal we may be to the germ theory.

1. Pneumococci may exist in the air passage without producing pneumonia.

2. The bacilli coli (which are constantly at home in large numbers in the large bowel) are believed by some to be essentially the same as the typhoid fever bacillus of Eberth and to develop the same biologic and pathogenic characteristics when the soil is favorable. Indeed it is freely stated that the Klebs-Löffler bacillus is often found among the many scores of bacteria infecting apparently healthy mouths.

In a recent paper Bleyer says: "To-day we know with almost absolute certainty that there are two forms of diphtheria, which to the eye of the clinical observer present similar changes in the mucous membrane, inasmuch as both are characterized by the appearance of a pseudo-membrane, at times dirty white, often tinted greenish or yellow white in color. Viewed at the bedside alone, in both you will observe alike, prostration, a febrile condition, swelling of the submaxillary glands, disturbance of respiration often slight it is true, so that a differential diagnosis, clinically, is a qualification to which few of us can lay claim. Notwithstanding this, the two are totally dissimilar. Examined bacteriologically, the exudate of one will reveal nests of bacilli which are found only in the exudate of true diphtheria, while in the other there are no bacilli, but instead the so-called staphylo- and streptococci. The first variety is highly fatal, statistics showing a mortality of almost 50 per cent., while the second, so far as danger to life is concerned, is comparatively harmless." In this latter statement he is wrong, for even these causes may produce fatal blood poisoning.

Skigo reports several cases which he met with during an epidemic of diphtheria where the tonsils were covered with disseminated spots of exudate the size of a pea, and he tells us that there was absolutely no clinical indication by which he could differentiate the cases which ran the violent course of true diphtheria, and those which took the milder course.

Morton examined 200 cases of diphtheria that had been diagnosed by that eminent clinician, Simon of Paris, and found in only 137 of these the Klebs-Löffler bacilli; 43 of the remaining 63 cases proved to be tonsillitis, 13 proved to be croup of which 12 got well without operation, 7 cases proved to be diphtheria with croup, 6 of which developed the bacilli after the operation of tracheotomy had been performed and which Morton says had been due to hospital infection.

In recent investigations made by Park, in the New York Orthopedic Hospital, where the children seem specially liable to attacks of follicular tonsillitis and enlarged tonsils, culture experiments were made and in some instances pure cultures of the typical Klebs-Löffler bacillus were found in fair abundance and in others they were scanty. Though the soil was favorable, the bacilli found were evidently not of a virulent character, and from these reports, Chappell, in the *New York Medical Record*, observes that until these causes were examined, he had supposed that Klebs-Löffler bacillus found in a sore throat meant diphtheria, whether the clinical history and evidence supported that diagnosis or not. He concludes that

at present writing it seems there are three possibilities:

1. Clinical phenomena of diphtheria without Klebs-Löffler bacilli.

2. Clinical phenomena of diphtheria with Klebs-Löffler bacilli.

3. Klebs-Löffler bacilli without any clinical phenomena of diphtheria.

If it be true that diseases attended with the formation of the pseudo-membrane of the throat due to other causes than the Klebs-Löffler bacillus are not followed by the well-known sequelæ of diphtheria, then the term diphtheria, should not be applied to them. The term, diphtheria, has in the past been freely applied to this form, but I think it is a misnomer. The name diphtheroid, which was first applied I believe by Dr. Lester Hall of Kansas City, is much more appropriate, as it expresses the thought that the disease is like diphtheria.

It is said that there is no germ that is so variable in its virulence as the Klebs-Löffler bacillus, (but all forms of life vary in their degree of lustiness) and this may account to some extent for the difference in severity in cases of diphtheria; we are all aware of the fact that there is a great variation in the virulence of all epidemics; whether it be due to atmospheric or other causes, has not been fully established. Another element of confusion to the practical physician is the statement that the pseudo-bacillus found in diphtheria does not vary in any way microscopically from the true Klebs-Löffler bacillus. If this bacillus and others may vary so materially in their lustiness, in their ability to make their way in the world from time to time, may they not also vary in their general appearances to a like degree, and thus create confusion as regards microscopic diagnosis?

In a recent discussion, Dr. C. H. Johnston, of Grand Rapids, Mich., says he can see no good reason for considering these so-called pseudo-bacilli as other than true diphtheritic germs, which if planted upon suitable soil may give rise to the most severe forms of diphtheria.

The many conflicting facts presenting themselves to us, may, if they do not prompt us to ask ourselves pathologically, "where are we at?" at least make us hesitate in insisting upon the making of a diagnosis based only upon microscopic demonstrations. Indeed, in spite of the brilliant light which has been thrown upon the subject from the intellectual lamps of many of the best men of the profession the world over, there is reason for our not being entirely absorbed in our study of diphtheria as well as other diseases, by the microscopic and bacteriologic evidence to the exclusion of the bedside clinical evidence.

While personally I am disposed to accept the germ theory, particularly as applied to the infectious diseases, and probably to far more than have yet been discovered, yet I still believe most firmly that there are many diseased conditions dependent upon other things than germs and that clinical facts are stubborn things.

Every true physician never ceases to be a medical student, and he needs to guard himself against too readily accepting the dictum of those whom he may recognize as the masters of the profession. The views of Lawson Tait and the many other able workers of the medical world are worthy of consideration, worthy of being weighed in the balance. I have great respect for the opinion of any man who has given evidence

of being an earnest, honest student in science, no matter what his views may be. Our own Dr. Wm. Johnston, one of the Nestors of the medical profession of St. Louis, one of the most indefatigable delvers in the field of literature, medical and general, when he antagonizes the germ theory of disease, we must remember is in very good company and his views are worthy of our most profound attention. At the same time the younger workers in the scientific vineyard who spend most of their time looking through the small end of a microscope and into the depths of test-tubes, mingling with laboratorial outfits, should have a care lest they develop an intellectual myopia which will preclude their appreciation of the importance of bedside observation, of clinical evidence. They should each and every one remember that bacteriology is not all of the science of medicine, and that the bulk of medicine is art rather than science, and other things being equal, the careful student of human nature, the close observer and the energetic worker in the sick room, after years of experience, is often far more competent to make a diagnosis of a given disease by clinical evidence alone than they, with their microscopes and culture tubes, without such knowledge and experience. Who of us who have listened to the able and forceful words of a venerable teacher of surgery in St. Louis, his teachings based upon knowledge gained from reading not only books but the symptoms of disease, would not as soon accept his dictum with reference to a tumor, its benignancy or malignancy, its necessity for removal, as the most expert microscopic opinion taken alone.

Any physician of experience worthy of the name, can make a diagnosis of pulmonary tuberculosis on the clinical evidence alone, and bring the microscope to his aid only for confirmatory purposes. But the true physician is ever receptive and unprejudiced whether in the sick-room or the laboratory—he who knows it all generally knows very little.

Like syphilis, diphtheria is probably primarily local, as it can be inoculated upon a denuded surface, but like syphilis, general in its effects, it so promptly affects the system at large that the removal of the infected point by the canterization of the membrane in the one case or the excision of the primary chancre in the other, will not prevent constitutional systemic poisoning. Time was, when in an empirical way, physicians immediately attacked these exudates in the air passages with violent caustics, often doing greater injury to the surrounding parts than to the invading membrane.

As syphilis has been in modern times greatly modified and its asperities softened by the recognition of the importance of local cleanliness and the securing of favorable constitutional conditions, so I believe may diphtheria. A suitable soil with depressed constitutional conditions, in other words a dirty suppurating neglected angina (as in scarlet fever, acute tonsillitis or quinsy) with perverted secretions throughout the alimentary canal, an already existing blood poisoning produced by the numerous streptococci and staphylococci present in the faucial field, presents conditions favorable to the development of the most brutal and lusty Klebs-Löffler bacilli imaginable.

One should hesitate long before relinquishing many of the valuable measures which have stood the test of time, and accepting the newer therapeutic sugges-

tions, even including that of Behring, for he undoubtedly originated and developed the antitoxin treatment of diphtheria. Roux, who is a skilled bacteriologist, and presented remarkable results in a definite manner at the International Congress of Hygiene at Budapest last summer, freely accords the credit of this discovery to Behring. The literature that has been presented during the past few months in favor of the blood serum therapy as applied to diphtheria, is enormous, and no candid careful observer can ignore the fact that the great bulk of it is favorable.

Nearly a hundred years ago, Edward Jenner presented to the world the original thought in the direction of treating disease in man by a product from a lower animal which had previously been acted upon by the same disease. In other words, Jenner's application of vaccination for smallpox was the first move in the direction of the blood serum therapy, for we have no reason to doubt that vaccinia on the udder of the cow is probably primarily the result of smallpox introduced into the same animal. It is true that the workers in this field are now moving along scientific lines and not empirically as did Jenner, and yet he stands an example to all scientists whether they be bacteriologists or bedside physicians, illustrating the thought that in the study of symptoms, the grasping of facts, the application of them, clinical work is after all one of the best means of demonstration in the hands of the physician. It will be remembered, too, that Jenner did not publish to the world his work until he had elaborated it, perfected it, and extended it over a period of twenty-five years.

The best report of the antitoxin treatment of diphtheria has been through the United States Marine-Hospital Service. Surgeon-General Walter Wyman having delegated Surgeon J. J. Kinyoun, a skilled bacteriologist, to visit the Pasteur Institute and study thoroughly the work of Prof. E. M. Roux, he presents his official report in the weekly abstract published by the Marine-Hospital Service under date of Oct. 20, 1894, and it is indeed the most succinct and reliable article upon this subject that has yet appeared. Too great credit can not be given Surgeon-General Wyman and his subordinate, Dr. Kinyoun, for the report. The essence of the conclusions made by Dr. Kinyoun are contained in the following: "The results obtained by Professor Roux in the treatment of cases of diphtheria are so astounding, that one is almost compelled to ask one's self, 'Is this possible?' but when the methods are known and the array of statistics are given, there can hardly remain a trace of doubt. The future possibilities in this direction can not be over-estimated as we have in the serum the almost absolute preventive of epidemics of diphtheria."

The great Virchow was for a time opposed to this method, but in a recent meeting of the Berlin Medical Society, he publicly announced that he had to yield to the brute force of unanswerable facts. A full opportunity was furnished for the comparison of results in a large number of cases in Berlin, when treated with and without the blood serum. Hausman, Virchow's assistant, still opposes the blood serum, but as yet there has appeared no presentment of facts upon which to base his opposition; at least it has escaped my observation. The reports from London, France, Berlin and upon this side of the water, are in the affirmative. The government of France has given to Roux its highest honors in recognition of his work.

And now what shall be said of the present general application of the blood serum therapy? First of all, the remedy is enormously expensive. The animal best adapted for its development is the horse, and the time required is not less than six months. This practically places it beyond the reach of the great masses. If the serum treatment is to become general, then comes the important question, and it is a difficult one, what arrangements are to be made for protecting the community under sufficient and proper guarantee with the material for this treatment? Surely the same arguments would apply in favor of this prophylactic measure (for such it is, as well as a remedial agent) being placed under the control of local boards of health, the same as in vaccination for smallpox. It is to be supposed that health boards have definite knowledge and supervision of the vaccine farms which furnish vaccine virus to the respective communities, and they should have similar supervision over the laboratories where the blood serum is developed. The health boards should know that properly healthy animals are secured, those of proper age, and that the proper sanitary and antiseptic precautions are exercised in the establishment. Even granting that the blood serum therapy has proved its case, until it is available, and even after, we must not lose sight of other remedies which have after long service proved of value, for there can be no doubt that considering the fact that the antitoxin antagonizes only the Klebs-Löffler bacillus and not the streptococcus and staphylococcus and other pyogenic microorganisms, we are never safe in ignoring our old therapeutic friends in favor of the exclusive use of the new. Reviewing the amount of confusion that exists even among bacteriologists regarding the definite cause of diphtheria, and the different kinds of diphtheria, and the like confusion and uncertainty pertaining to the blood serum therapy, and our inability to make it generally applicable to mixed infections, we are justified in the exercise of the extreme caution in its application.

Diphtheria poison is tenacious of life and may be transported indefinite distances. The disease is always more or less present in crowded communities, possibly inhabiting permanently the sewerage systems of cities. Laboratorially demonstrated, the Klebs-Löffler bacillus is admitted to be found in seemingly healthy mouths frequently. A large number of the children in every community at certain seasons of the year through the medium of follicular tonsillitis, enlarged tonsils and catarrhal disturbances of the air passages, and scarlet fever angina, present themselves as standing invitations to diphtheria. A bacteriologic demonstration of true diphtheria requires twenty-four or forty-eight hours. Remembering all these facts, every case of sore throat should be isolated and treated as a suspect. While in no case acting as an alarmist, the physician should be a guarder and a protector of his patients, and should from the beginning inform the family of the possibilities of any sore throat developing into a diphtheria.

The foregoing being true in every case of sore throat, the treatment from the first should be antagonistic to diphtheria, locally and constitutionally, no matter how benign it may appear, no matter whether the Klebs-Löffler bacillus be suspected or discovered. Every case of sore throat should be treated in a cleanly way and every hygienic rule should be observed. The ideal treatment for tonsillitis, the an-

gina of scarlet fever and la grippe, which may be classed under the head of suspects, is a favorable preliminary treatment for any case of diphtheria, and this is briefly, a prompt purging of the patient, emptying the intestinal canal for future service as a food tract, the administration of local applications which serve as soothers and cleaners of the disturbed mucous membranes and are as nearly germicides as can be made. Under this head comes hydrozone and pyrozone, which are definite strengths of peroxid of hydrogen, and if too irritating may be diluted one-half. This application should be followed by Listerine, Pasteurine or Katharmon, applied preferably with a hard rubber syringe, the nozzle of the same guarded by a soft piece of rubber tubing two or three inches long, to protect the throat from being wounded. The keeping of the nasal passages well open by the means of liquid albolene (5 grains of carbolic acid to each ounce) protects the mucous surfaces and renders the infection at these points less probable. The internal administration (from the beginning) of the benzoate of soda, in doses ranging from 5 to 20 grains, well diluted with plain water every one or two hours, according to the age of the patient, serves as a stimulator of secretions and is the best remedy for prompt reduction of a benign inflammation of the tonsils, it being equally valuable in the removal of exudations. A dry engorged condition of the mucous membranes with all secretions presenting a tenacity and a disposition to stick to the surfaces, is soon changed under the saturating doses of the benzoate of soda, into a loosening of all exudations and a moist condition of all the surfaces. A flow of mucous from the parts is stimulated and exosmosis rather than endosmosis is encouraged. Salkowski in 1879 announced that saturated solutions of the benzoate of soda rendered the diphtheria membrane, if bathed in them, absolutely inert, so that the remedy is more or less locally antiseptic. In addition to the remedy suggested, the bichlorid of mercury should be given from the beginning, starting with 1-50 of a grain or even 1-32 well diluted, to a child of 2 years, and increasing in proportion to the age, for at least twenty-four hours, the same dose to be continued every two or three hours thereafter as long as the conditions call for it, unless too free a catharsis be produced. Clinical facts deduced by others, as well as those coming under my own observation, are absolutely convincing that the internal use of the bichlorid of mercury is antagonistic to the toxic effect of the diphtheria poison, the same as it is to the Lustgarten germ of syphilis (if there be one) and to all other germs as well, including even tuberculosis when given discreetly, and it is a local antiseptic.

Our forefathers were not far wrong when they gave calomel and other forms of mercury in reasonable doses to their cases of diphtheria, typhoid fever and cholera; but mercury is not the only remedy which has for centuries been given empirically and yet proved to be scientifically correct. We have been giving opium for two thousand years as a reliever of pain, and yet we do not know how it acts; we only know that it does.

The thoughtful physician should never lose sight in the management of his throat cases, of feeding, and indeed within twenty-four or forty-eight hours, having placed the alimentary canal in the best possible shape for the digestion and assimilation of food, the nutrition, in a form to be readily digested (use it

predigested if necessary) and assimilated in proper quantities at proper times should be furnished, for after all, good well fed blood can repel successfully most of the bacilli and their toxins. Stimulation should be ever kept in mind but not applied too soon. When we recall the demoralization of the digestive tract and the nerve centers produced by the excessive use of alcohol in adults, we should have a care in our administration of alcoholic stimulants to delicate children. I have found a pine-apple peptic wine known as Zumo-Anana of great service as a stimulant. Remedies, either local or constitutional, should not be given so frequently or be of so irritating a character as to interfere with the digestive function or with the proper amount of rest on the part of the patient.

To epitomize, then, whether the blood serum therapy be applied or not, our treatment of our diphtheria cases should include a full regard for:

Elimination, the keeping open of the secretory and excretory system of glands.

Disinfection, local and general, of the attacked surfaces, the patient and his environment, should be applied, even though the case be only a suspect and present none of the evidences of the more infectious disease.

Nutrition of a character to be most promptly utilized, and nothing is better in this direction than peptonized milk, and milk has the advantage in this form of being soothing to the inflamed surfaces of the throat. Ice cream made of good materials is often gratefully received by the patient and is quite digestible.

Stimulation, but not until it is required, for he who crosses his bridges before he gets to them makes a mistake. Oats are better for the thorough-bred roadster than the whip, unless the latter be used upon the animal when in the middle of a bridge which is breaking down; and then the whip serves well to spur the flagging energies, and so with stimulation in disease.

Tranquillization both of body and mind should be the rule from the beginning, and to this end the victim should never be given the diagnosis of his case, and no application, no remedy, nothing should be permitted to interfere with a full amount of sleep within the twenty-four hours. If necessary, sedatives to secure rest should be given and they should be given for an effect. Small doses of a sedative often excite, whereas large ones result happily.

Rest is one of the sweetest words in our language, and in the management of no disease is this more true than in diphtheria.

In closing, let me insist upon the thought that in the majority of cases the microscope is only valuable for the confirmation of the diagnosis, though exceptionally it is essential to the making of a diagnosis, and whether we get our own consent to the application of the blood serum therapy or not, let us never lose sight of the proper toilet of the throat, the proper use of our accepted and well tried remedies in addition.

The child with sore throat, as well as the other members of the family, should be given the benefit of the doubt, and isolated and treated always with the possibilities of diphtheria in mind.

**The Forty-sixth Annual Session of the AMERICAN MEDICAL ASSOCIATION** will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

# TABETIC FOOT WITH PERFORATING ULCER. (MAL PERFORANT DU PIED.)

Read before the Chicago Pathological Society, Dec. 10, 1894.

BY HAROLD N. MOYER, M.D.

ADJUNCT PROFESSOR OF MEDICINE IN RUSH MEDICAL COLLEGE,  
CHICAGO.

Male, 48 years of age, of previous good health and vigorous constitution, a sailor by occupation, contracted syphilis fourteen years ago. Two years later an ulcer began on the right toe; at first there was some swelling of the epidermis on the inner aspect, and a bleb formed. This gave way and an ulcer remained that gradually deepened until it extended in a funnel-shaped excavation to the bone. After this the toe was amputated. The following winter the third toe on the right foot became diseased and was removed. From that time on the patient was free from all disturbance about the joints, with the exception of the gradually developing deformities,

until the winter of 1893 and 1894, twelve years after the onset of the malady in the right foot, when the great toe of the left foot became similarly affected necessitating amputation.

In January of that winter he began to have pain in his stomach, his gait became uncertain, and there was a numb sensation from the knees down. Since that time he has been unable to work. He has now well-developed tabes, marked incoördination, loss of the light reflex, gastric crises, but no lightning pains. The feet show the loss of toes that have been amputated and also a clubbed condition of the second toe on right foot where there is a large callus and no nail. The second toe of the left foot is gangrenous. The whole foot is deformed and distorted. There is a thickening of the metatarsal bones, and disease and deformity of the bones and joints which make up the arch of the foot. An examination of the accompanying photographs will show that the medio-tarsal joint

is the most involved. Not only are the bones eroded and displaced, but there is more or less thickening of the cartilaginous and osseous structures forming the arch of the foot; so that the foot is humped much as it appears in dislocations of the medio-tarsal joint, but unlike the latter condition the foot is not in an equinus position and the plantar surface can be brought to a right angle with the axis of the leg.

There are two principal varieties of tabetic arthropathy of the foot; in one we have the medio-tarsal joint involved, with a projection of the arch of the foot; in the other the disease seems to expend its force largely upon the ankle joint and the articulations between the astragalus and os calcis. In these cases the foot is in extreme extension; in one figured by Charcot there is a dislocation of the ankle and the foot forms a direct continuation of the long axis of the leg.

To Charcot and Féré<sup>1</sup> we are indebted for the term tabetic foot. In 1883 they reported two cases of this

disease and priority is commonly accorded them. Page,<sup>2</sup> the previous year, had described a case of tabetic arthropathy in which the tarsal bones of both feet were involved. In 1884 Féré<sup>3</sup> reported an additional case. Since that time cases have been reported by Boyer,<sup>4</sup> Joffroy,<sup>5</sup> Chauffard,<sup>6</sup> Longuet,<sup>7</sup> Féréol,<sup>8</sup> Kramer,<sup>9</sup> Chipault,<sup>10</sup> Audocond<sup>11</sup> and Klemin.<sup>12</sup>

In some of the cases, perforating ulcer was associated with the deformity of the foot such as we have in this case, but they are not necessarily associated, as each condition may occur separately and apart from the other.

So far as I am aware, Bernhardt<sup>13</sup> reported the first case of perforating ulcer in connection with tabes. This was followed by cases from the pens of Pepper,<sup>14</sup> Hinze<sup>15</sup> and Audocond.<sup>16</sup> Hinze,<sup>17</sup> in a later communication, collected twenty cases from the literature and two additional ones occurring in his own practice, in all twenty-two; of these nineteen

were men and three women. In eight cases the ulcer preceded outbreaks of tabetic symptoms and in ten they followed. In three cases the ataxia and ulcer appeared at the same time, while in one the fact could not be ascertained. The longest time noted by Hinze in which the ulcer preceded the tabes was ten years. It will be seen that in the case under consideration this length has been exceeded, some twelve years having intervened between the appearance of the perforating ulcer and the first symptom of tabes.

A number of different theories have been propounded to account for the trophic changes in tabes. Charcot believes it to be due to an atrophy of the cells in the anterior horns of the cord, while Virchow simply referred it to lowered nutrition due to perverted nerve influence. Oppenheim and Siemerling demonstrated a change in the peripheral nerves, but it is apparent that such conditions may be only secondary. Volkmann pointed out the relation of traumatism and analgesia in these cases. Undoubtedly, in advanced forms, these factors play an important rôle. It does not account, however, for those cases in which the joint troubles precede by months or even years the earliest tabetic symptoms. As a matter of fact, our knowledge of the trophic centers of the nervous system is yet too slight to throw much light on the pathology of these cases.

An interesting case of perforation of the aortic valves was reported by Teissier<sup>18</sup> in a tabetic. The case presented a close resemblance to the ordinary perforating ulcer of the foot, and was thought by him to have an identical pathology.

Terrillon<sup>19</sup> has reported a unique case of multiple perforating ulcers of the hands in a case of tabes of syphilitic origin.

the sheer force of pathologic necessities approaching its proper position in frequency of performance. The expressions quoted are used almost exclusively by men who have not yet realized the pathologic conditions nor the true importance of early operation. Their intellectual vision is still in the shadow of the "grape seed," "cherry pit," "catarrhal inflammation," and "rheumatism" of the appendix. They have not the slightest idea of the destructive effect of an infection of the appendix. They do not realize that with an infection, the appendix may become completely gangrenous, may perforate or may produce a fatal peritonitis all in a short period of time (forty-eight hours), from the initial symptom. Again, it is said by the same class of men: "I am opposed to the indiscriminate removal of ovaries and appendices when they are not seriously diseased." So is every rational operator and this idiotic expression should not be tolerated in medical societies without appropriately stamping its author.

There has been no controversy in the history of medicine in which the struggle has been so intense between the surgeon and the physician as on that of appendicitis. Both parties have been honest in their convictions and both equally positive that they are right.

We naturally seek an explanation for this diversity of opinion as well as action, and the explanation is not difficult to discern. Differences of opinion as to the clinical course and probable results with operative and non-operative treatment have been almost entirely due to erroneous notions of the pathologic conditions. Up to five years ago we had on the pathology of appendicitis practically no other teaching but that of the post-mortem table; that has to-day been almost entirely superseded by the teaching of the operating table. To-day we observe on the operating table pathologic changes almost from the moment of their beginning until the destruction of the parts concerned is complete; whereas formerly we made deductions, and these very erroneous ones, as to conditions that existed before the pathologic changes ensued which produced death.

From results found post-mortem we inferred the cause and course, and here was the source of error; to-day we observe the disease in the various stages of its progress from its inception to the final result. We are therefore preëminently qualified to arrive at a correct conclusion, inasmuch as our opportunities are so much greater for observing pathologic changes as they progress.

Now, on what points have the surgeon and the physician differed and what has led to the diversity of opinion?

From 1886 to 1888, when Gaston and Kraft wrote their excellent monographs on appendicitis, it was the prevalent opinion of the profession all over the world that the vast majority of diseases in the right sacro-iliac region were due to cecitis, an inflammation of the cecum or its surrounding tissues as a result of disease of that viscus, and it was variously known as typhlitis, perityphlitis and cecitis. Then, after these elucidations, the physicians gradually yielded point after point until finally, to-day, it is agreed that all except 2 per cent. of the inflammatory pathologic lesions about the caput coli are due to primary lesions of the appendix.

We may now regard the first point as practically settled; the next argument advanced on theoretical

## APPENDICITIS.

### DEDUCTIONS FROM TWO HUNDRED AND SEVEN CASES OPERATED, WITH TABULATED REPORT.

Read before the Chicago Pathological Society, Dec. 10, 1894.

BY JOHN B. MURPHY, M.D.

CHICAGO.

Professor of Surgery and Clinical Surgery, College of Physicians and Surgeons, Chicago; Professor of Surgery, Post-Graduate Medical School and Hospital; Attending Surgeon to Cook County Hospital; Attending Surgeon to Alexian Brothers' Hospital; Consulting Surgeon to Hospital for Crippled Children, etc.

In many of the recent periodicals we find these ideas expressed: "The pendulum of operative appendicitis is now swinging in the reverse direction." "The frequency of operation on the appendix is going through the same course as did removal of the uterine appendages." The frequency of operation has not been irrationally swung, nor carried to its present position so-called excessive, but has found the strongest opposition from the very onset and is only now by

considerations was that the appendix in inflammatory infections becomes swollen, and relieves itself by the discharge of its inflammatory products through its normal opening into the intestine, thus effecting a cure.

What have we learned from observations at the operating table? That in inflammatory lesions of the appendix, the canal is rarely relieved of its inflammatory products in the way suggested, but is relieved by a necrosis of its wall and perforation. This is followed by the formation of an abscess and a subsequent necrosis of the attached wall of the viscus to which it is adherent, the contents of the abscess escaping into the intestine.

The next contest was over the presence or absence of pus outside of the appendix, in the majority of acute cases. Observation in operations has shown us that in the acute stage, in 94 per cent. of the cases, pus is found outside of the appendix; that the existence of pus outside of the appendix does not necessitate a perforation of that organ for its production. That an infection of the peritoneum and the formation of a peri-appendicial abscess may occur with an internal ulceration of the appendix and no perforation, as I have shown by cases reported in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*,<sup>1</sup> March 3, 24, 1894.

While the profession was not prepared to believe that pus was present in the form of a circumscribed peri-appendicial abscess in practically all of the cases of acute appendicitis, it had been acknowledged for many years that in some cases abscesses occurred around the caput coli, which emptied into the intestinal tract and the patient recovered. We know now that this is the course in the very great majority (about 82 per cent.) of cases that recover without operation.

The last and final questions, and the ones on which the controversy is still spirited, are: *a*, the pathologic changes produced by perforation of the appendix into the peritoneal cavity; *b*, the likelihood of that perforation, and also perforation of the circumscribed abscesses about it, into the peritoneal cavity; *c*, the immediate and remote symptomatic and physical manifestations of the latter; *d*, the ultimate result of such rupture; and *e*, the danger of infection of the peritoneum from an endo-appendicitis without perforation.

The pathologic changes produced depend: 1, on the character of the material admitted into the peritoneal cavity, *i. e.*, whether the contents of the appendix or abscess consist of, *a*, pus or *débris* in which the staphylococcus predominates; *b*, whether the streptococcus predominates; *c*, whether the bacillus coli communis exists in its virulent or inert condition; and *d*, whether the pus, in which any or all of these may have existed, has become innocuous; 2, the quantity of material admitted at one time into the peritoneal cavity; 3, on the condition of the peritoneum at the time of admission of pus.

I have observed in patients, and demonstrated experimentally, that pus in which the staphylococcus and the inert bacillus coli communis predominated, could be free in the peritoneal cavity for a long

period of time and produce but very slight changes in the peritoneum, *i. e.*, that the intestine may be bathed in pus of this character for days without excoriating the peritoneum. I have observed a pint of pus of this character in the peritoneum of a patient where the history showed conclusively that it must have been present for five days, and upon opening the peritoneal cavity the normal gloss of the peritoneum of the bowel was still maintained. I have taken this pus and produced cultures with it which demonstrated its character, and injected one drachm of the pus as removed from the peritoneal cavity into the peritoneal cavity of animals, both with and without mechanical abrasion of the peritoneum, without producing any symptoms, and no pathologic lesions were found on making an autopsy.

In cases of general suppurative peritonitis, as a result of appendicitis, that have been under my observation, in which the normal glistening appearance of the peritoneum was present at the time of operation, the patients recovered, and inoculations of the pus into the peritoneal cavity of animals produced no symptoms or lesions. When I find that the pus has not abraded the peritoneum, even though the surface has been covered by it for a length of time, I consider the case a favorable one.

Note how this contrasts with the appearance in the abdomen where the streptococcus predominates. Here we find, within a short time after the rupture into the peritoneal cavity, the peritoneum in contact with the infectious material is entirely denuded of its endothelium, resembling the condition produced by a cantharides blister. The quantity of pus is always small, rarely exceeding a few drachms, with here and there flakes of lymph. The bowel is distended and paralyzed; peristalsis has ceased. Inoculations with this pus produced the same condition; the red and angry appearance of the intestine I now recognize as a signal of the gravest importance, as the majority of my cases in which this condition was present terminated fatally.

The septic conditions of the bacillus coli communis produced about the same physical manifestations as that of the streptococcus. The quantity of material discharged into the peritoneal cavity is of great significance; if it be small the intestines and omentum rapidly circumscribe it and protect the general peritoneal cavity from invasion. If it be large, and if it be irritating and poisonous, it may abrade the peritoneum of its endothelium as boiling water would, quickly, and be followed by a rapid absorption, causing death in a few hours. I have had only one case of this class in which an abscess of considerable size ruptured into the peritoneal cavity; within two hours the extreme symptoms of shock were present and in twelve hours the patient succumbed. If a large quantity of pus of a low septic character be admitted into the peritoneal cavity, it may remain in that cavity for days and produce but slight changes; finally, from some cause, this material which had been innocuous, suddenly produces grave conditions and symptoms.

It is a matter of deep-rooted belief that a peritoneum that has been irritated repeatedly by the presence of a tumor, by the close proximity of an accumulation of infectious material finally attains an increased resistance against infection, *i. e.*, the peritoneum of a patient who has suffered from the presence of a large and movable tumor will tolerate much

<sup>1</sup> Dr. Fowler also made the same observation and in the *Annals of Surgery*, January, 1894, expresses himself as follows: "From the first appearance of an endo-appendicitis, channels of infection are open which may lead to the occurrence of any one or all of the forms of septic peritonitis without the occurrence of perforation, formation of adhesions, or rupture of a sero-purulent collection of an abscess cavity."

more manipulation than a perfectly normal peritoneum, and that the peritoneum in the neighborhood of an old circumscribed abscess is more difficult to infect than a healthy peritoneum.

There has been a great difference of opinion as to the symptoms of appendicitis and the relation of the symptoms to the pathologic condition within. This diversity will continue until our power of differential diagnosis is very much increased. From a train of symptoms and signs in the early stage it is impossible to say just what is the exact pathologic condition. We can say, however, that it is a disease of the appendix in some stage of its development.

The symptoms of appendicitis are: 1, a sudden pain in the abdomen; 2, shortly followed by nausea and perhaps vomiting; 3, local tenderness over the site of the appendix, and most frequently in the right iliac region; 4, elevation of temperature.

These symptoms occurring in this order without a previous history of genito-urinary infection, lesions of the gall tracts or Pott's disease, indicate appendicitis with almost uniform regularity. They do not indicate that the appendix is gangrenous or that it is a simple catarrhal appendicitis. They do not indicate whether the appendix has perforated or has not perforated; nor whether the cause is an infection with the staphylococcus, streptococcus, bacillus coli communis or the presence of a fecal stone or a foreign body. They do not indicate whether it is stenosis of the appendix or an appendicitis obliterans but merely that it is an appendicitis, a disease of the appendix.

The physical manifestations, the presence or absence of induration, tumefaction, edema of the wall, tympanites, etc., aid in the differentiation of the various pathologic conditions present in the more advanced stage, but all of these are absent or comparatively worthless in the early stage.

The etiology, which was for a long time a subject of contention, is now practically agreed upon. It was very difficult to eradicate from the professional mind the deep-rooted erroneous belief that in a great majority of cases, appendicitis was due to foreign bodies admitted into and retained in the appendix, as grape stones, cherry stones, fragments of bone. We had four cases of foreign body and 38 per cent. of fecal stone. To indicate the causes of appendicitis, I will use the same classification employed in my article of March 3, 1893:

1. Simple pus infection, producing the catarrhal variety.
2. Extensive infection by bacillus coli communis or pyogenic microbes, producing gangrene of a greater or less portion of the appendix.
3. Pressure atrophy with infection of the appendix: *a*, by fecal concretions; and *b*, by foreign bodies.
4. Retention accumulations: *a*, from cicatricial contractions, stenosis and obliteration; and *b*, from occlusion by enterolith or foreign body.

From the reports of autopsies collected, I find that in 70 per cent. of the cases there was a perforation of the appendix. Of my own cases in which the appendix was removed there was about 80 per cent. perforated. Simple catarrhal primary appendicitis, if it exists, is rarely brought to the attention of the physician and still less frequently to that of the surgeon. Of 207 cases reported we had but one of this variety. A catarrhal inflammation where the more serious form of appendicitis had previously existed is not uncommon.

The question of greatest practical importance to the surgeon and physician is the diagnosis; can we determine when an appendicitis is present, and can we determine the pathologic conditions that exist in the abdomen at any given time in the progress of the disease? To the former we must with positiveness answer in the affirmative; to the latter an equally forcible negative must be given, that is, we can say from the symptoms that a lesion of the appendix exists but we can not say, in most cases, how extensive, how dangerous and how far-reaching the effects of that appendicitis may be, and still less can we say in any given case how soon the life of the patient may be greatly jeopardized by the disease which at the moment has apparently no grave symptoms.

If we were able to determine in the early stage from the symptoms, physical signs or clinical history of a given case that it was going to take a favorable or unfavorable course, we could regulate our treatment accordingly. Unfortunately, there are no symptoms present in the dangerous cases, premonitory of their fatal termination, until the patient has passed beyond the stage where an operation offers reasonable hope for a recovery.

The question to be answered is, When should we operate?

The so-called conservative answers: "Operate on the collapsed cases; the cases that present symptoms of fulminating peritonitis; the cases that are taking an unfavorable course; the cases that appear to be progressing rapidly to destruction under medical treatment."

The surgeon must take a positive stand and answer, No, to each of these rules. It is admitted that 50 per cent. of the fatal cases terminate before the end of the sixth day, many on the fourth and a smaller number on the second.

The surgeons who wait till the sixth day must therefore expect to have a mortality of 50 per cent. of all the cases that would die without operation. I believe the proper position for the true, earnest and advanced medical man is expressed by the eminently scientific and truly conservative physician, Dr. Norman Bridge, in the following words: "Appendicitis is one of the most frequent and dangerous of the inflammatory diseases in or about the peritoneal cavity. We do not know the line between proper medical treatment and the demand for surgical interference, and rather despair of finding it. The medical man is practically powerless to control the destiny of the patient. It is always a surgical disease and the mortality should be materially lessened by skillful surgical treatment."<sup>2</sup> Would you delay operation in a case that is progressing favorably? By that I mean a case in which the temperature is not above 99 degrees, the pulse not above 80, the expression good, the abdomen presenting no alarming symptoms. No; I have seen cases of this class go to the third, fourth and fifth day with all of the most favorable symptoms that could well be imagined and on the sixth day die. From what? From a suppurative peritonitis that had existed all that time, as shown by the pathologic changes found in the peritoneum.

*We have no sign, symptom or combination of signs and symptoms which indicate with any degree of certainty, suppurative peritonitis. It may exist and the free*

<sup>2</sup> Prof. Wm. E. Quine, whose name is synonymous with rational conservatism has said: "I am convinced that early operation is the most scientific treatment for appendicitis with our present knowledge of the pathologic condition."

peritoneal cavity contain drams of pus with the patient about town as the following case illustrates. The case occurred in the practice of Dr. Jas. G. Berry:

Patient, G. F., aged 19, weighed 220 pounds. On the morning of September 8, after breakfast, was attacked with a severe pain in abdomen, shortly followed by vomiting, and the pain and discomfort were sufficient throughout the day to prevent him from attending to his work. He remained about the same during the night, and the following morning, at 10 o'clock, twenty-six hours after the onset of pain, he walked a couple of blocks to the drug store and consulted the druggist concerning his trouble, who advised him to see a doctor, and he was seen by Dr. Berry at 3 o'clock; diagnosis of appendicitis made; his pulse when seen by Dr. Berry was 140 and temperature 102 degrees; no tympanites, increased local tenderness over the region of the appendix, peristalsis absent, patient's countenance good and expressed himself as feeling tolerably comfortable. At 4 o'clock, assisted by Drs. Berry and McQuaig, I did a laparotomy. On opening the peritoneum, pus flowed out; there were no adhesions whatever between the intestines; the appendix was free; a fecal stone protruded from an opening in the side of appendix, where it had produced a pressure atrophy perforation; appendix amputated; abdominal cavity sponged; pus found down in the pelvis; gauze drained. The normal gloss of the intestine was not disturbed in the least by presence of the pus and the surface was not even red. Patient made an uninterrupted recovery. It will be noticed that the operation was performed thirty-three hours after the onset of symptoms and but a few hours after the patient had been walking about in the street with a suppurative peritonitis. What would have been his condition if the operation had been delayed twenty-four or forty-eight hours? The answer is self-evident.

A retention appendicitis, on the other hand, may produce a temperature of 105 degrees or even greater, enormous tympanites and pulse 140, an anxious facial expression and all of the so-called classical symptoms of a peritonitis, and the peritoneal cavity be free from infection. (See report of case which occurred in practice of Dr. E. W. Lee, JOURNAL OF AMERICAN MEDICAL ASSOCIATION, March 3, 1894. These are extreme pictures, but they do occur.

When should we operate? As we are unable from the signs and symptoms to determine the exact pathologic condition, are we justified in allowing the probability of fatal conditions to continue for such a period of time without such action as would place the patient beyond the possibility of rescue even by operative procedure? No; until such time as the physician is able to determine the exact pathologic condition and danger in the individual case, and indeed we must now consider that time far distant, he is not justified at the peril of the patient's life in restraining the surgeon from acting.

It must be conceded by all, that an operative procedure, in competent hands, is in itself one involving very little risk, while the continuation of the pathologic processes in many cases greatly jeopardizes the life of the patient.

There is only one safe position to take, and that is in every case in which a diagnosis of appendicitis is made, the operation should be immediately performed. It is true that many cases can recover without operation, but we can not differentiate, in the early stages which cases are going to be favorable ones. It is further true that the earlier the operation is performed, the less the danger to the patient and the greater the ease of removing the appendix.

In a majority of cases, if an operation be performed within forty-eight hours after the onset of the symptoms, the appendix is not yet ruptured and can be removed without pus infection of the peritoneum, an advantage of which even the boldest surgeon is pleased to avail himself. The following case in the

practice of Dr. Hoelscher is a beautiful illustration of this class:

Date of operation, Nov. 10, 1894. Operator, Dr. J. B. Murphy with Dr. J. H. Hoelscher. Diagnosis, appendicitis. Patient, Miss T., aged 16, was perfectly well up to 4:30 p.m., November 9, when she was attacked with pain in the abdomen, which persisted and increased in severity, compelling her to go to bed. She began to vomit at 8:30 p.m., and vomiting and pain continued through the night and up to the time of operation. At 11:30 of that night, when seen by Dr. Hoelscher, temperature was normal; the diagnosis of appendicitis was made. At 8 a.m., November 10, temperature 99.5 degrees and pulse 90; at 11 a.m., time of operation, temperature 100 degrees, pulse 110. Very tender over region of appendix; not sensitive in any other portion of the abdomen; no tympanites; peristalsis absent in close proximity to the appendix; expression good. Dr. Hoelscher is to be congratulated on his early diagnosis.

Operation: Lateral incision. Appendix covered entirely by peritoneum, adherent to the posterior surface of cecum up on to the ascending colon. End enlarged to half an inch in diameter; contained no fecal stones, but was full of pus; gangrene of mucous membrane beginning: lymph flakes in outer wall of appendix. Appendix ligated and removed without rupture; peritoneum sewed over; gauze drainage. Patient made an uneventful recovery.

In the later stage, if the surgeon is unfortunate enough to be called at the time that the peritoneum is flooded with pus and the patient collapsed, it is his duty perform the operation and give the patient the advantage of the small percentage in his favor in this forlorn condition.

*The rule first, last and always should be: Operate in every case of appendicitis, promising or unpromising, at the earliest possible moment.* What operation shall we perform? The incision should be made a little toward the median line from the highest point of induration, parallel to the rectus; the muscular layer should be separated with the handle of the scalpel parallel to the course of the fibers, as advised by McArthur and McBurney, and thus lessen the liability of hernia. The opening must be ample to allow the surgeon to perform the work within with ease.

In the early cases the appendix should be removed, as the adhesions are friable and permit of the appendix being readily separated and drawn into the field. The parallel band of fibers on the cecum, opposite its mesentery, can always be followed to the position of the appendix and is an infallible guide to its location.

If the non-infected portion of the peritoneal cavity be opened before the abscess is reached, as is always desirable in the early stage, a thorough packing of gauze should be made around the induration to prevent the gas from entering the unaffected portion of the peritoneum. This I consider of very great importance, and I make an effort to enter the peritoneal cavity just to the side of the adhesions, so as to open the unaffected portion of the peritoneal cavity before I open the abscess; in that way the adhesions may be located and the packing well placed, so as to thoroughly protect the peritoneum before the adhesions are torn.

In the later cases, that is, from the seventh day on, I consider it advisable to open directly into the abscess where adhesions to abdominal wall are present, drain the abscess, remove the fecal stone, if one be present, and make no effort to remove the appendix. The appendix in the acute cases should be simply ligated with chromicized catgut; no effort should be made to top-sew it or bury it in the cecum. Occasionally there will be a fecal fistula, but that closes in a very few days itself.

In the cases of appendicitis operated on in the intermediate stage *i.e.*, between the attacks, a cuff should be made of the peritoneum of the appendix, peeling the peritoneum back one-half inch or more; the mucous and muscular layers ligated and the cuff drawn back over the stump of mucous membrane and ligated. The pus should be carefully sponged out of the cavity and no water or disinfecting solutions used; do not waterlog the peritoneum as it is sufficiently taxed in taking care of the pus without this additional labor. A glass and gauze drain should both be used in all cases in which pus is present at the time of operation or in which there has been a recent attack of appendicitis. The drain can be removed in eight or ten days as the cavity fills up from the bottom.

This, in short, is an outline of the procedure I follow. All of the minor details can not be mentioned here. There is no operation in the peritoneal cavity where the patient's life is so completely in the hands of the operator, where the errors of doing too much or too little work would be so likely to result fatally as in the operation for appendicitis, with its multi-form and complicated pathologic conditions. The results depend in a very great degree on the extent of the invasion, and the latter upon the period of time that has elapsed since the onset. In speaking of results, I do not mean the results in recurring appendicitis, the simplest and least dangerous variety of all; I mean the results in all classes of cases, from the general suppurative peritonitis as a sequence of appendicitis, to the simplest catarrhal variety.

There is a growing tendency in the profession to shirk the responsibility of operating where the dangers are great, *i.e.*, to defer operation on the most dangerous cases and advocate operation on the obliterated or stenosing recurrent varieties in which there is the least danger to the life of the patient from the disease. We must not swerve from our obligations to our patients, but make every effort to rescue them, regardless of the praise or condemnation bestowed upon us.

In reporting the cases, it is the duty of every operator to classify or mention in detail the important or common symptoms of each individual case in a tabulated form and give an abstract of the history and pathologic conditions, that the analytical mind in reviewing the results obtained by the individual operators may be able to explain the cause of their success or failure when the operator himself is not. Therefore it is the duty of every surgeon, in writing on this subject, to give sufficient details of his cases to enable the reader to judge why they were of the grave or mild variety; whether they were all cases of recurrent, simple, adhesive appendicitis, or whether many of them were of the gangrenous, perforative and malignantly infectious variety with the peritoneum extensively involved.

*(To be continued.)*

**A MEDICINE MAN SLAIN.**—A medicine man of the tribe of Puyallup Indians, named Jim Bonchette, was killed by Jerry Dominic, another Indian belonging to the Muckleshoot Reservation, in the State of Washington, for the reason that the former had failed to cure the sickness of three of the children of the latter.

## ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

*(Continued from page 404.)*

### CHAPTER VII.

#### MICROSCOPIC AND CHEMIC EXAMINATION OF BLOOD.

The color of the venous blood was purplish, between that of arterial and venous blood. When a drop of blood was allowed to fall upon a sheet of white bibulous paper, a central bright red spot remained with a surrounding bright golden aureole of serum, which spread around the central corpuscles by capillary action. The blood coagulated very slowly and formed a large loose coagulum, or clot, which contracted slowly and imperfectly. Thus in the 1,000 grain specific gravity bottle the coagulum filled the whole bottle, and from this amount of blood not more than 150 grains of golden-colored serum could be collected at the end of forty-eight hours. The blood corpuscles tended to rapid dissolution in the serum, and upon long standing the serum changed from this cause to a bright red. The reaction of the blood was most carefully determined as it flowed from the veins, and was found to be slightly alkaline, as is usual in healthy blood. I regarded this observation with interest as in several cases, in which I had abstracted blood from the cavities of the heart, after death, it gave a decided acid reaction; but the present observation would seem to show, that the acid reaction was due to post-mortem changes. Immediately after its abstraction, the blood was subjected to a careful and rigid microscopic examination. Under a magnifying power of one-fifth of an inch (Smith & Bucks, of London, best objective glass), many of the blood corpuscles presented an irregular stellate outline. When viewed under high magnifying powers, as the one-eighteenth inch immersion lens of G. & S. Merz, of Germany, with eye glasses, to magnify 1,050 diameters, the crenated and stellate blood corpuscles were found to be studded upon the surface, with nodular rounded projections. The colored blood corpuscles appeared to be undergoing changes of form, as if nodular transudations of the globulin were forming upon the surface. These changes were most marked and frequent, upon the surface and outer portions of the clots, and resembled in some respects the amœboid movements of the coalescing corpuscles; the nodules were, however, uniformly diffused over the surface of the corpuscles. When the blood was examined, from the interior of the clot, the corpuscles were found conglomerated together forming rolls or piles, adhering together by their flat surfaces, like the rouleaux of the blood of inflammatory diseases and of the horse. The corpuscles which had been joined and agglutinated together by their flat surfaces, were normal in shape, and presented no stellate or nodulated outline as was the case with the corpuscles from the surface of the clot, and from the surrounding golden serum. It appeared as if the nodulated exudation had formed the bond of cement between the opposing flat surfaces. Upon standing twenty-four hours and longer, the colored corpuscles tended to dissolve and lose their outline, and the serum became colored from the escape of the coloring matter of the red globules.

The colored corpuscles appeared to be acted upon and altered by the urea and bile which chemie analysis revealed in considerable amount in the serum. After standing in an open beaker or in porcelain capsules for forty-eight hours, numerous vibrios made their appearance, as in other putrefying animal fluids, as blood, albuminous urine, and serous exudations. But no living animalculæ or vegetable cells or spores or pigment granules were discovered even after the most diligent search with high powers, ranging up to the twenty-thousandth of an inch objective, in the fresh blood. The blood drawn from the arm during life putrefied much more slowly than that taken from the heart and large blood vessels after death. The blood was carefully examined by the best and most reliable chemie methods, and was found to contain a comparatively large amount of this constituent; large and well formed crystals of urea, and of the nitrate of urea, were obtained from comparatively small quantities of blood.

As much urea was obtained from 100 grains of the yellow fever blood as is ordinarily obtained from 7,000 grains of healthy blood. The serum was also carefully tested for bile, and was found to contain all the ingredients of bile. The blood also contained numerous small oil globules and in one of the specimens a distinct oily scum rested upon the surface of the clot. So striking was the oily appearance of the blood that it was noticed by the medical students who assisted during the bleeding. The presence of the urea in increased amount, and of the bile in the blood, were due to the suppression or arrest of the functions of the kidneys and liver. To the presence of these substances in the blood must be attributed in part, at least, the delirium, intoxication and aberrated muscular and nervous action, and to a certain extent the nausea, vomiting, gastro-intestinal irritation and black vomit. The altered shape of many of the colored blood corpuscles was certainly due, in a great measure, to the physical and chemical action of the urea and bile of the serum. Specific gravity of venous blood from the arm of this yellow fever patient, 1055.6. The density of this blood was somewhat below that assigned by physiologists and pathologists as the standard of healthy blood. Thus Becquerel and Rodier give the density of the defibrinated blood of the male as 1060, and of the female as 1057.5.

The specific gravity of the serum of the venous blood from the arm of this yellow fever patient was 1027. The specific gravity of the serum, therefore, did not differ materially from that of health; according to Becquerel and Rodier, the density of the serum of the male being 1028, and of the female 1027.4. The serum was of a deep yellow color, similar to the yellow color of the liver and of the diluted bile from the gall bladder of yellow fever subjects. Clot, soft, large, and without any very great contractile power. After the contraction of the clot the serum was tinged of a red color, from the presence of colored corpuscles and the coloring matters of the blood. The amount of serum forced out of the clot was relatively small and appeared to possess the power of dissolving the colored corpuscles upon standing in contact with the clot, the red color increasing gradually in depth. In these respects the yellow fever blood presented a marked contrast to healthy and inflammatory blood. Only 108 grains of serum could be obtained from a vessel containing 890 grains of blood.

Fibrin in 1,000 parts of venous blood abstracted from the arm of this yellow fever patient, 0.271. The fibrin was greatly diminished, being only one-tenth of the quantity present in the normal blood. The fibrin itself appeared to be of the usual tenacity, and the imperfect contraction of the clot appeared to depend rather upon the small amount of fibrin, than upon any physical or chemical change in the constituents of the blood. In the marked diminution of fibrin, we have a most interesting and important explanation of the cause of the hemorrhagic tendency in yellow fever.

The following are the chief characteristics of the blood in the stage of depression in yellow fever, as established by the preceding chemie analysis:

Specific gravity of blood and serum not specially altered.

Blood coagulated slowly and imperfectly.

Clot voluminous and soft.

Fibrin, quantity deficient and not more than one-tenth the normal amount.

Reaction of blood alkaline.

No deficiency of colored blood corpuscles, the dried blood corpuscles being 130.57, and the moist blood corpuscles 522.28. The organic matters of the moist blood corpuscles are normal in amount, while the fixed saline constituents are diminished, being only 1.78 in the blood corpuscles of 1,000 parts of blood.

The relation of the moist blood corpuscles to the liquor sanguinis, as far as quantity was concerned, was not disturbed, the former standing in relation to the latter in the 1,000 parts, as 522.28 of the blood corpuscles to 477.72 liquor sanguinis.

The albumen of the liquor sanguinis was diminished to a marked degree, being only 53.40 parts in 1,000 parts of blood. The extractive matters of the liquor sanguinis were increased. The extractive matters were complex, and included bile, urea and ammonia. The fixed saline constituents of the liquor sanguinis was not diminished. Without doubt the loss of albumen, as well as the presence of bile, urea and other excrementitious matters in the serum or liquor sanguinis, determine to a certain extent, at least, the character of the capillary circulation and the production of black vomit. The patient died twelve hours after this observation. The kidneys never acted and he appeared to die from the combined action of the febrile poison, bile, urea and other excrementitious matters, and the loss of blood during the slow but persistent hemorrhage from the gastro-intestinal mucous membrane.

Autopsy twelve hours after death: Exterior, superior portions of face, trunk and upper portions of limbs of a deep golden orange color. The lower dependent portions of the face and of the trunk and limbs were of a mottled, purplish, yellow and livid maculated appearance, as if the patient had been beaten with a club. The general appearance of the exterior of the body was horrible. Black vomit had run out of the corners of the mouth, and saturated the winding sheet, and had trickled in a muddy filthy stream along the sides of the face and neck. Features full and somewhat swollen. Belly full and tympanitic. Well formed muscular man, in the full vigor and strength of manhood. Large well developed chest, with full pectoral muscles. Arms full and round, with good muscular development. The left knee appeared to have been injured at some previous time, at least months if not years before the fatal illness.

The patella was displaced downward and outward laterally, and the joint was ankylosed. A small ulcer existed upon the outer aspect of the left knee joint, below the edge of the displaced patella. The left leg was a little shorter and smaller than the right. I had the bones carefully cleaned after death, and found that they had been altered by chronic inflammation, which had been attended with certain changes of the bony structure. This injury was of long standing, and had nothing whatever to do with the present attack, as the patient was able to perform active labor up to the time of his last illness, and the parts in and around the joint presented no swelling or discoloration. The patient appeared to have been suddenly cut off in full vigor and health, and in death resembled one into whose veins a deadly poison had been injected by a venomous reptile, which had not only poisoned, but also enveloped in its powerful coils and strangled its victim.

Head: Dura mater, pia mater and arachnoid membranes congested with blood. The brain was congested with blood, not only in its membranes but also throughout its textures. The brain and its membranes, however, presented no marks of inflammation—no exudation. Membranes of spinal cord congested with blood. The congestion of the blood vessels of the brain appeared to be similar in all respects to that of the capillaries and small blood vessels in the different organs and tissues. The consistency of the brain was normal. Weight of brain, two pounds and fourteen ounces; it was carefully tested for bile and urea. The infusion of the structures of the brain presented a bright golden color, like that of the serum. When carefully tested, the presence of the coloring matters and acids of the bile was conclusively determined in the cerebral structures. When the decoction of the brain was evaporated in a watch-glass and examined under the microscope, numerous beautiful stellate and prismatic crystals of the phosphates of lime, and ammonia and magnesia made their appearance.

When carefully tested for urea, according to the best methods known to chemists, the alcoholic extract obtained from the water extract was found to be literally loaded with the product of the metamorphosis of the tissues, and as large a crop of perfectly formed and characteristic crystals of the nitrate of urea were obtained as from an ordinary specimen of urine of moderate specific gravity. The brain contained more urea than any other organ, the liver not excepted. It was clearly established by this chemic examination that the urea existed in much larger quantity than in the healthy brain, or in the brains of those who die from diseases in which the action of the kidneys is not diminished.

Thorax: The pericardium was congested. As is usual in yellow fever, the capillaries and small blood vessels of the pericardium presented a beautifully arborescent appearance from the accumulation of colored corpuscles. I have in my possession a portion of the pericardium of a yellow fever patient, which I preserved by simply spreading upon a glass slide, and after drying, saturating with Canada balsam and covering with a glass slide. The preparation shows an intense congestion of the blood vessels and capillaries, and so numerous are the colored corpuscles, and so brilliant the colors, that the preparation resembles the best injections with the most brilliant carmine. The pericardial sac contained about two

ounces of bright golden colored transparent serum.

The heart presented a brownish-yellow appearance, resembling the pale flabby heart of scurvy. The textures although softer than in the normal heart, were, however, firmer than in well marked fatty degeneration. The muscular textures of the heart required considerable pounding in the mortar to reduce them to fragments sufficiently small for decoction. The decoction of the heart in distilled water was loaded with golden-colored oil, which floated in a thick scum upon the surface, and it resembled in its rich oily nature the richest soup made from the marrow and fat of the bones of fat well fed animals. The fat was far more abundant than is usual in the heart of malarial fever or other diseases in which there is no fatty degeneration of this organ. The filtered decoction of the heart was of a golden yellow color. The decoction of the heart contained bile in abundance. As the decoction of the heart, after careful filtration, slowly evaporated in a porcelain capsule, a deep orange-colored ring formed around the sides of the vessel. Weight of heart, eight and one-half ounces. Both cavities of the heart contained blood. Several small, ropy, golden-yellow clots were also discovered in the cavities of the heart. The muscular tissue of the heart appeared to have lost its tenacity and to have become relaxed and somewhat softened; and this view was confirmed by microscopic examination. The heart was also carefully tested for urea, and this substance was clearly detected in considerable quantity, but in relatively less amount than in the brain. Under the microscope, oil was found in the form of minute globules, diffused through all the tissues of the heart, and even within the ultimate muscular fibers. The muscular fibers of the heart presented under the microscope, a granular appearance, and the transverse striæ were not as distinct as in normal hearts. The increase of free fat or oil in the structures of the heart was therefore determined by the microscope and by actual experiment. The heart contained therefore in comparatively large amounts, bile, urea, oil.

No animalculæ or vegetable cells or spores were observed under the one-eighteenth inch immersion objective of Merz, either in the blood or textures of the heart.

*To be continued.*

## THE EARLY DIAGNOSIS OF CARCINOMA OF THE STOMACH, WITH THE BACTERIOLOGY OF THE STOMACH CONTENTS.

BY FENTON B. TURCK, M.D.

PROFESSOR OF DISEASES OF THE STOMACH AND INTESTINES, POST-GRADUATE MEDICAL SCHOOL; ATTENDING PHYSICIAN TO THE COOK COUNTY HOSPITAL, CHICAGO.

(Concluded from page 406.)

Abelous (*Revue de Therap. Medico-Chir.*, April 1, 1890) found sixteen species of microorganisms in his own stomach after fasting; ten of these he asserts could form lactic acid. This has not been corroborated by other similar experiments. Abelous makes no control, nor does he prevent contamination from the mouth and esophagus. In Miller's experiments the stomach contents were secured from a patient who could regurgitate the contents at will at any time. After disinfecting the patient's mouth with bichlorid 1 to 1,000, Miller secured the contents of

the stomach. On examination he discovered many microorganisms which he had previously found to be present in the mouth, among these the *bacillus lacticus*.

The esophagus is a perfect culture bed. Its folds form a favorable nidus for microorganisms. Unless this is specially considered, error may arise, since contamination from the esophagus easily takes place.

The lactic acid forming bacilli can be found in the stomach in health, as well as in disease. However, it is doubtful whether the colonization of the *bacillus lacticus* can be demonstrated in the healthy stomach, to such an extent as in carcinoma, and more particularly carcinoma pylori.

#### CHEMIC METHODS.

The presence of lactic acid in the stomach contents is determined by Uffelmann's and Nessler's reagent. The quantity of lactic acid in the stomach contents is estimated by Boas' method. This is as follows: The patient's stomach is washed out with sterilized water in the evening. The patient then takes oatmeal gruel which is prepared by boiling a tablespoonful of oatmeal and a pinch of salt, in 1,000 ccm. of water. In the morning the stomach contents are drawn off and filtered. The filtrate is concentrated upon a water-bath, until a reaction with Congo red paper fails. Barium carbonate is then added which combines with the lactic acid to form a lactate. This is brought to the boiling point, to drive off the CO<sub>2</sub> and volatile substances. The lactate is then treated with phosphoric acid which sets free the lactic acid. This is extracted with ether; the ether evaporated, and lactic acid mixed with alcohol remains. The residue is then treated with an oxidizing agent, to change the lactic acid to acetic aldehyde. It is here where Boas' method is faulty; alcohol when oxidized also forms an aldehyde. To avoid this error, Dr. Wesener made an essential modification: before oxidizing the lactic acid which may also contain alcohol, Wesener treats the residue with barium carbonate, and evaporates nearly to dryness. This drives off the alcohol and does not affect the lactate. The lactate is again treated with phosphoric acid and boiled, to remove the CO<sub>2</sub>. After this, Boas' method is carried out: The solution is diluted with 45 ccm. of water and 5 ccm. of sulphuric acid, and about 30 to 40 grains of black oxid of manganese added. This solution is placed in a 200 ccm. flask which is connected with a Liebig condenser and gently boiled, and distilled until four-fifths of the material has passed over. (The lactic acid has been converted into acetic aldehyde.) The distillate is treated with 20 ccm. of a decinormal solution of iodine, and 20 ccm. of a normal caustic potash solution. At this point iodoform, potassium iodide and iodite are formed; 20 ccm. of HCl, sp. gr. 1.018 is added which liberates all of the iodine not used in the formation of iodoform. Sodium bicarbonate is used to neutralize and a decinormal arsenic solution is added in excess. The excess of arsenic is filtrated back, with a decinormal iodine solution. Starch is used as the indicator. The difference in the number ccm. of decinormal iodine and decinormal arsenic solution is equal to the iodine required to change all of the acetic aldehyde to iodoform. This result is multiplied by .003,388 which equals the lactic acid present in the stomach contents used. Compute to 100 and this represents the percentage of lactic acid.

#### BACTERIOLOGIC METHODS.

For bacteriologic purposes the contents of the stomach are taken:

1. From the fasting stomach.
2. After a test meal according to Ewald.
3. After test meal according to Boas (oatmeal soup at night and withdrawn next morning).
4. The stomach is washed out with sterilized water and the water that remains is aspirated.

The gyromele is introduced according to the method as described in the *Wiener med. Wochenschr.*, Nos. 1 and 2, 1895. To avoid error of contamination, the mouth and esophagus should be cleaned. Microscopic examination is made of the contents. A stain is irrigated through, by placing the stain on one side and a blotter on opposite side of the cover-glass. When any field of interest is presented it can be divided and mounted according to the usual methods.

Drop cultures are made from the stomach contents, using the contents as a nutrient media. The development of bacteria under the microscope may be observed for hours in succession. The observation of the growth of some of the algae is very instructive by this method. Line cultures may be made upon the sterilized mucous membrane of the stomach of pigs.

The mucous coat is dissected from the muscular coat, stretched upon a glass plate and sterilized at 50 to 55 c. four hours each day for one week. The ordinary moist chamber allows contamination to take place. To avoid this I devised the following method: A glass battery jar is placed upon a common dinner plate; a second jar of larger size is inverted so as to cover and inclose the first jar; a solution of 1 to 1,000 bichlorid is poured into the plate to form a water valve; a few folds of filter paper interposed between the inner and outer jar prevents rapid evaporation. Two glass tubes pass from the outer jar to admit air and when plugged with cotton prevent contamination. This moist chamber is sterilized and the culture plate placed in the inner jar, and sterilized by fractional sterilization as before mentioned.

Thus the coagulation of the albumin is prevented. The ordinary sterilized platinum needle is used, dipped into the material derived from the stomach. Line cultures are made by drawing it lightly over the surface of the sterilized mucous membrane used as the culture bed. Five or six strokes or lines are sufficient. The third line will isolate colonies for pure cultures (fished under the microscope fifty diameters). The colonies can be forced without melting the medium, and it furnishes as near a natural culture bed as possible for artificial cultivation.

To favor the development of lactic acid microorganisms, the surface of the culture medium may be sprayed with a thin mixture of starch water. When desired the mucous membrane can be dried like parchment and the colonies preserved *in situ*.

Nutrient gelatin and agar-agar for tube cultures. This is prepared by the usual method, except in place of beef extract, I use the extract from the mucous membrane of the stomach of pigs; 5 to 20 per cent. of gelatin is added, or 1 to 2 per cent. of agar-agar. The addition of sugar to the culture material is often an advantage in the study of stomach bacteria.

*Liquid Media.*—Extract from the mucous membrane is prepared by taking one-half kilogram of finely minced mucous membrane of the stomach of a pig, covered with 1 liter of distilled water and left in

the refrigerator for twenty-four hours. This may be sterilized by fractional sterilization as in the preparation of blood serum. To this may be added starch, grape sugar, milk, or brewers' liquid malt, which must be obtained fresh from the brewery. This is used for the study of fermentation and germs of putrefaction.

In place of the extract of the mucous membrane, I find it an advantage in some cases, to use the sterilized filtered contents of the stomach. This can be prepared and kept for use as desired.

The method of preparing the stomach of living dogs for the study of the growth of bacteria found in the human stomach has been referred to on page 317 of the JOURNAL.

#### CONCLUSIONS.

1. Carcinoma of the stomach early creates a soil for the rapid development of microorganisms.

2. The lactic acid forming germs grow more readily in carcinoma of the stomach than in other diseases of that organ.

3. Lactic acid germs found colonizing in the stomach are of great diagnostic value in carcinoma.

4. The absence of germs does not exclude carcinoma.

5. The determination of lactic acid of fermentation by Boas method, as modified by Wesener, is of diagnostic value.

## SOCIETY PROCEEDINGS.

### American Electro-Therapeutic Association.

Fourth Annual Meeting held in New York Academy of Medicine, New York, Sept. 25, 26, and 27, 1894.

(Continued from page 286.)

WILLIAM J. HERDMAN, M.D., President.

#### AFTERNOON SESSION.

The meeting was called to order by the President at 2:30 P.M.

MR. W. J. JENKS, M.A.I.E.E., of New York City, read a paper on

#### DIRECT CURRENT DISTRIBUTION.

When I was asked to contribute a paper at this time I replied that I had nothing to tell which could be of service to those who used electricity on the spot where it was generated, and applied it without distribution over large areas to purposes of which I have but a vague comprehension. I had expected, in becoming an Associate Fellow, to gradually inhale a medical atmosphere, which like a fresh supply of oxygen from the rarefied air of an unusual altitude, would bring to my own mind and body greater vigor. But I had not counted upon exhaling any ideas which might help to establish a reciprocal relation between the medical and the engineering factors of this Association. If therefore I succeed in doing so, I shall enjoy an unexpected pleasure, and you may credit with whatever useful suggestions I may offer, the account of our good friend the Secretary, by whose courteous invitation I am here.

I hesitate very much to attempt, in the presence of a gathering of trained scientific observers, any re-statement of established truths, and in apology for so doing I offer to you only the assurance that every such repetition makes the principles which underlie electrical action seem clearer to my own mind. I am in a measure reassured by the thought that even to the vision of the most eminent physicists of these closing years of a marvelously fruitful century, many phases of the production and operation of the mysterious servant which we are trying to harness, are still seen only "through a glass darkly."

My knowledge of your science is not sufficient to enable me to do more than suggest, with much diffidence, one or two lessons which my own department of electrical work may possibly teach physicians. If there are others, I am sure your perception of the necessities of your section of the art will promptly recognize and apply them.

Until we know what electricity is, we can not accurately define "electrical distribution." We may conceive of the behavior of electricity as resembling or analogous to that of a liquid stored in reservoirs or flowing in pipes; we may speak of its development and the transmission of power by its aid from point to point as the generation and circulation of a current; we may imagine that we are handling a ponderable substance when we measure the effects produced by its presence or by the expenditure of its energy.

Whether it should be called a tangible though imponderable entity, or an ether-like medium which may be started into vibration or circulation by the expenditure of energy, or simply one of the group of fundamental forces by which all created things are held together and maintained in that state of vibratory change which is the life of the material universe, it is not necessary that we now inquire, and if it were, I should not stand here and attempt to answer. It may be useful for us to recall the definition given by our distinguished Honorary Fellow, Prof. E. J. Houston, in his "Electrical Dictionary":

"Electricity.—The name given to the unknown thing, matter or force, or both, which is the cause of electric phenomena.

It is but fair to state that the author of this paper considers it practically unintelligible without illustrations, which unfortunately, for want of time, must be omitted in this publication.—EDITOR TRANS-ACTIONS.

Electricity, no matter how produced, is believed to be one and the same thing. The terms *frictional-electricity*, *pyro-electricity*, *magneto-electricity*, *voltaic or galvanic-electricity*, *thermo-electricity*, *contact-electricity*, or *animal or vegetable-electricity*, etc., though convenient for distinguishing their origin, have no longer the significance formerly attributed to them as representing different kinds of the electric force."

In this definition we find a foundation for the statement (which is important in considering the limitations of the subject assigned to me) that if we form a clear conception of the comparatively simple phenomena of the distribution of direct currents, (constant in direction), we shall be prepared to appreciate to a greater degree the complicated and involved phenomena which appear when we distribute currents of alternating direction. I have taken the liberty to depart slightly from the letter of my topic as announced, in order to include currents which are always *the same in direction*, irrespective of whether they are "constant" in the sense employed by electrical engineers, that is, of unvarying strength or rate of flow. As a part of the groundwork of this discussion it may be convenient also to remember that such currents may for practical purposes be excited by primary or secondary chemic batteries, magneto or dynamo-electric machines or pyro-magnetic generators, though the last-named source of electrical energy is still in what we may call an experimental stage for the purposes of producing any considerable electro-motive force.

I may perhaps be excused for illustrating some features which attend distribution from either of these sources in the way which makes the results most clear to my own mind. Possibly the method may not appeal as plainly to others.

It is only about fifteen years ago that the electrical engineer was called to deal with the distribution over large areas, of currents representing many mechanical horse-power. The possibility of doing this work commercially was a direct result of the discovery by Faraday of the law of magneto-electric induction, by which for the first time the product electricity was secured at a cost which bore a reasonable relation to that of the power required to excite it. For seventy years the world was in possession of the most brilliant and efficient source of light which man had ever devised, the electric arc, without applying it to the illumination of streets and houses. Such applications suggested themselves to Sir Humphrey Davy in 1810, but there were grave difficulties to be overcome. One of these, the wasting of the carbons, which are in part vaporized and in part dissipated by ordinary combustion, was overcome by the invention of regulators or arc lamps.

The second arises from the operation of that inexorable law which, (in the language of a noted scientist) throughout the material universe demands an eye for an eye and a tooth for a tooth, refusing to yield the faintest glow of heat or glimmer of light without the expenditure of an absolutely equal quantity of some other power. Hence, in practice, the desirability of any transformation must depend upon the value of the product in relation to that of the power expended. The metal zinc can be burned like paper; it might be ignited in a flame, but it is possible to avoid the introduction of all foreign heat and to burn the zinc in air of the temperature of this room. This is done by placing zinc foil at the focus of a concave mirror, which concentrates to a point the divergent electric beam, but which does not warm the air. The zinc burns at the focus with a violet flame, and we could readily determine the amount of heat generated by its combustion. The zinc can be burned not only in air but in liquids. It is thus burned when acidulated water is poured over it; it is also burned in the voltaic battery. Here, however, to obtain the oxygen necessary for its combustion, the zinc has to dislodge the hydrogen with which the oxygen is combined. The consequence is that the heat due to the combustion of the metal in the liquid falls short of that developed by its combustion in air, by the exact quantity necessary to separate the oxygen from the hydrogen. Fully four-fifths of the total heat are used up in this molecular work, only one-fifth remaining to warm the battery. It is upon this residue that we exclusively depend, for it is solely out of it that we manufacture our electricity.

So ruinously expensive is this process of burning zinc when the electrical engineer is called to develop large powers, that the world waited, as I have said, until it was discovered that those other and greater storage batteries, the coal beds, which represent the activity of ages past, might be pitted against the waterfalls, which represent Nature's activity of the present, in a grand competitive effort to provide man with a magic wand in response to which all the mighty forces of the sunlight and the ocean would marshal themselves to do his bidding.

It was some time before the electrical engineer acquired confidence in his own ability to produce and distribute successfully the high pressures demanded by many street lamps in series, and to handle the lower potentials when expended at the rate of hundreds or thousands of volts for each ohm of conductor or translator resistance.

The coming of the electric arc lamp, requiring nearly a horse-power of mechanical energy for each large unit of light, and the softer incandescent or glow lamp which only gave from one hundred and ten to one hundred and twenty-five candles of light for each mechanical horse-power, usually in the form of seven or eight lamps of sixteen candles each, demanded an electric current representing 1,000 horse-power for each 1,000 arc lamps required for the lighting of the streets of a city, or each 7,000 glow lamps for stores and dwellings.

There is perhaps no more impressive example of almost irresistible power than a modern high speed locomotive and its vestibuled limited express train flying at the rate of a mile a minute between the great cities of the United States. The total weight of such a train is from 400 to 500 tons, or from 800,000 to one 1,000,000 pounds, and a speed of seventy-five miles per hour is sometimes attained. The energy of 400 tons moving at that speed is nearly twice as great as that of a 2,000 pound shot fired from a 100 ton Armstrong gun. But these illustrations express a power only about one-half of that which was last year constantly required for the lighting of the art gallery at the World's Columbian Exposition by 16,000 incandescent lamps. Because under ordinary circumstances the electric current speeds along the motionless conductor without causing a quiver or vibration perceptible to our eyes or ears, we are apt to overlook the fact that its power for great usefulness and instantaneous transmission of a variety of manifestations of energy, when properly directed, is equalled by its ability to do serious mischief whenever it escapes from our control.

The possibility of commercially generating electricity on such a scale was only realized when the modern dynamo-electric machine was made practical and by its means the tremendous energy of motion derived from the power of waterfalls and steam boilers was substituted for the feeble combustion of chemic cells. The coils of the armature of the dynamo, being forced by the resistless pressure of steam to revolve between the poles of powerful magnets in the field of magnetic force, and in spite of the attraction with which that force opposes the revolution, develop and send out this marvelous agent which we call electricity, not in transitory sparks like the discharge of the Leyden jar, not in an almost microscopic wave like the pulsations of a telegraph or telephone circuit, but in a maintained succession of powerful throbs following each other in such close intervals of time as to constitute a practically uniform flow of any volume we desire, so that we popularly speak of it, for want of a better analogy, as if it were water or gas and moved in tangible particles from point to point.

The physician who desires to draw suggestions from the experience of the electrical engineer may profitably reflect upon a few primary truths which he may have known in the abstract, but which may never have been presented to him as possessing concrete importance.

1. Electricity is not a source of energy, but only an intermediary agent.

2. It has one fundamental characteristic by which we make it available, namely, *pressure*.

3. All its useful engineering results are accomplished by the expenditure of this pressure.

4. By providing a conducting track or circuit of considerable length, two objects may be secured; 1, transformation of energy; and 2, transference or transmission of energy.

5. The electrical pressure is expended in every part of the circuit (including the mechanism of the generator) in direct proportion to the resistance encountered.

6. It thus becomes possible to transmit and localize the expenditure of the electrical equivalent of the initial mechanical energy with which we start out, at any point or points desired, always considering the inevitable losses which take place in transformation and transmission; and to vary those losses within any limits which conditions of safety and of commercial investment may permit.

Let us discuss each of these statements with some care.

The engineering practitioner does not recognize in electricity a source of energy. He realizes that to obtain it he must expend some initial force that costs him money, and can never expect to recover all of what has been thus spent. He is not able to make electricity available to him as a force

which directly completes any useful operation. Perhaps there may be those here who can tell me whether in the application of electricity to the human mechanism, the mysterious agent is itself directly effective, or whether it can be relied upon only to convey to the proper point a potent energy, so flexible, so obedient to known laws, that the intelligent physician can predict the result of its transformation to heat, to chemic action, or to some other desired manifestation of what may be, for aught we know, a single all-pervading energy.

In the everyday application of electricity to commercial problems of distribution, it is an intermediary agent, having two great features of utility: 1, it transforms or translates one manifestation of Nature's forces into another; 2, it transfers energy (while in the intermediate state which we call electrical action) from point to point instantly. As an intermediary agent it is thus both a skillful magician and a swift-winged messenger. By its action, one manifestation of natural power, as for instance the motion of a waterfall, disappears, and in its stead another and more useful manifestation of heat, light or chemic action is developed, either in the same place or a different place, as we desire. When we wish it to transmit or transfer power, we connect with the source of energy a suitable path in the form of a material which readily conducts electrical impulses, and we find the power appearing at the objective point before we can realize that the transmission has taken place. Wherever, in the path thus provided we wish to do useful work, we place an obstruction which the electricity must overcome, and in the operation of surmounting such an obstacle a part, or practically the whole of its energy may be expended. While we can not tell what electricity is, we can say that for the purposes of practically generating and controlling it, it has but one element, namely, a "pressure," "strain," or "tension," which in systems of electric lighting, for example, is steadily generated by the dynamo, which is the mechanism in which the electrical force first appears, and that it is as steadily expended in the "circuit" or path by which we connect the outgoing and the incoming terminals of the dynamo, and with such instantaneous effect that the moment we connect such a source of power with a conductor forming a complete circuit, the pressure has traversed the entire path and has spent its entire force. At every point in this path, or, more accurately, between any two points, no matter how large or easy this path may be, we find that some fraction of this total pressure has been expended in exact proportion to the opposition it has met, or, in other words, to the resistance it has encountered. As long as the connection with the source of power is kept up, this generation and expenditure may be maintained; the instant we break the connection at any point in the complete circuit all action ceases, because the electrical pressure generated before the break occurred has been instantly used up or transformed into some other form of energy, such as heat, light, magnetism, chemic action or motion. The portion of the initial pressure which is inevitably expended between the point where it is generated and the point where it is made useful in a "translating device" is transformed into heat and disappears, thus being, so far as any useful result is concerned, lost or wasted. Hence the loss of pressure in transmission is often called "drop" in pressure, and the energy thus lost is known as "heat waste." The translating device may be a lamp, a heater, a motor, a plating bath or a magnet; in short, any mechanism within which the energy of electricity may be translated or transformed to some other serviceable form of energy.

Thus the function of all electro-generative apparatus applicable to systems of distribution is to develop or maintain, or both, a useful difference of potential between its terminals. If a direct current is to be interrupted or pulsatory, the potential difference may be momentary or transient; if the current is to be continuous, whether variable or constant in its strength, a useful potential difference must be sustained in spite of the opening of an outlet by the completion of a circuit, and the resulting tendency to a reduction of difference of potential to an equilibrium, with the expenditure of the initial potential.

It is difficult for us to conceive of the rapidity of electrical action. Whether we consider the transformation of chemic action or mechanical force into that form of molecular tension or pressure or strain which we call electro-motive force, or whether we think of its expenditure through a conducting path which forms a complete circuit we have, so far as our senses can discern, instantaneous conversion to electricity, and instantaneous expenditure resulting in heat, light, magnetism, chemic action or motion.

We can not then measure the rate of the expenditure of E. M. F. in time (so many volts per second), but we can measure its rate of expenditure in the resistance of the circuit (so many volts per ohm), and this rate of expending volts in each ohm is what we call the current or ampères.

When we develop electrical potentials we expend a measurable power, but afterward if the potential is not expended (that is if the charged body is perfectly insulated, by surrounding it by material which offers infinite resistance to oppose the pressure), no power is required to maintain it. Hence, in doing useful work it is not the first development of the potential which costs the effort or the money, but the maintenance of the potential when the restraining resistance is lessened and we allow the potential to escape or equalize itself at any rate (per ohm) which we desire.

The result secured in useful power from the expenditure of a maintained E. M. F., varies directly as the rate of expenditure in each unit of resistance, or in other words, directly as the ampères.

Thus the "volts" considered alone do not express the power required for generation, nor the power recovered in some useful result. Doubtless every one here present has often noted the very small power required to develop a frictional spark; yet that spark may represent a voltage far beyond that of any direct current dynamo now operating arc lamps in this city. In order to expend itself it has to overcome an enormous resistance in the form of an air space, and the rate of expenditure of volts per ohm of this great resistance is so minute that we have perhaps no instrument except the telephone which can detect it, and we can not even then measure the infinitesimal rate in ampères.

Nor is it the "ampères" alone which become a measure of the work done. Every member of this Association may have noted the uncertainty of attaining a current of a given number of milliamperes by the application of a given number of cells of battery in the treatment of any given tissue. The battery may be in some cases justly loaded with its share of blame because it may at any moment fail to develop its usual voltage, but you are dealing with an unknown, or only approximately known, or even a variable resistance, and the expending of 10 milli-volts per ohm (which is simply another form of expression for securing a current of 10 milliamperes) gives very little idea of the electrical power which is being expended in that part of the circuit formed by the tissue under treatment.

The rate of expending energy or doing work between any two points in an electrical circuit is known only when the total potential there absorbed or expended is found, and multiplied by the rate of such expenditure in each unit of resistance between the points considered. That is, it is only known when volts are multiplied by ampères, and is expressed by the resultant "watts." Here, in electrical distribution, we have the basis of a measurement of energy necessary to keep up the battery or turn the crank or pulley.

But the watts give only a rate of doing work. To know what aggregate work is done, we must add another factor, time. And so the physician should be able to record the three factors—volts, ampères and seconds, which alone can give the "joules" of energy expended or work accomplished either in heat developed, or chemic action stimulated. The time is at hand when by a single instrument, self-recording, the skilled electrical specialist may read on a tape (with the ease that cable operators now read by the siphon recorder of Lord Kelvin) the record of each application in total potential applied, rate of expenditure of volts in each unit of body resistance, variation of such resistance under the application of the electric energy, and duration of treatment.

In the distribution of electrical energy from a generating source to translating devices, the electrical engineer utilizes the laws to which I have referred by connecting the translators in one of two ways:

1. In series, so that the same current passes successively through all the devices.
2. In multiple arc or parallel, so that the entire current passes simultaneously through all the devices, each of which receives a fraction of the total.

The series or successive arrangement is roughly indicated in the upper diagram of Fig. 1. At the left of this diagram, I have indicated the generator by an upright spiral extending from a zero line at the base of the diagram to a line marked 400 and then bending over to the right and falling to an elevation of 300. By this I design to indicate that in the armature coils of the generator a total E. M. F. of 400 volts is generated, and that under the conditions assumed, 100 volts is expended within the armature itself, leaving 300 volts to be usefully applied to outside distribution. The

line extending to the right from the upper extremity of the spiral (at 300 volts) indicates a conducting wire, and the fall of the wire from the 300 volt line indicates that 50 volts have been expended in this division of the circuit. The two heavy vertical lines with a small space between them indicate the carbons of an arc lamp, and it is assumed that 50 volts additional is expended in this lamp, causing a sudden drop of the potential to 200 volts. Beyond this lamp comes another length of conductor, a second lamp, and a return conductor twice as long as each of the two upper sections of the line, and occasioning twice as much drop, or 100 volts. This brings us back to the zero point or negative terminal of the dynamo, and for convenience of illustration I have shown near this negative brush a current indicator standing at 10 amperes, which is assumed to be the normal current of the circuit here illustrated. The denominators of the several fractions (which are written in black) indicate the number of ohms resistance assumed to exist in the various parts of the circuit, 10 ohms in the armature coils, 5 in each upper division and 10 in the lower division of the line, and 5 in each lamp; 40 ohms in all. As it is assumed also that 10 volts is expended in each ohm (that is, 10 amperes of current flows) the number of volts indicated in red and to which I have already explicitly alluded, is found by multiplying the number of ohms by ten. It will be understood that I am here illustrating the law of series distribution by assuming an exaggerated case. No competent engineer would provide or recommend a dynamo in which would be expended 25 per cent. of the total energy produced; nor a conducting wire which would cause a drop of 50 per cent. of the total E. M. F. generated. It is, however, customary to use for series arc lamp circuits a size of wire which has a resistance per mile of about 5 ohms.

The middle figure of this diagram is intended to illustrate the same system after two or more lamps have been added, and while the dynamo is generating the same total E. M. F. of 400 volts. The only difference in the resistance of the system as thus modified is the additional 10 ohms introduced by the two new lamps, but this modification is sufficient to cause an entirely different distribution of the fall of potential. As the resistance of the entire circuit is now 50 ohms, the total 400 volts must be expended at the rate of 8 volts per ohm, and the ampere meter accordingly indicates 8 amperes. There is 80 volts drop in the armature, 20 volts in each of the four upper divisions of the line wire, 80 in the return and 40 in each lamp, under the assumption that although the current is reduced, the lamps have maintained their original resistance of 5 ohms. This reduction of the current flow causes an abnormally small light in each lamp, and it becomes necessary to take some action to restore the current flow to the normal standard of 10 amperes.

This restoration is accomplished by the process of regulating the generative capacity of the dynamo, or in other words causing it to generate a sufficiently higher total E. M. F. so that the fall of potential through each division of the circuit may be restored to 10 volts per ohm. This result is indicated in the right hand of the three sketches which constitute the upper diagram. The spiral indicating the generating coils is extended upward to show that it now generates 500 volts, of which 100 is absorbed within itself and 400 is expended in the outside circuit at the rate of 10 volts per ohm. The ampere meter again indicates 10 amperes. From this it also appears that the dynamo attendant may be guided, in the operation of a series system, entirely by his ampere indicator, the current being the constant factor in the operation of such a system.

It may be convenient in this connection to summarize the peculiarities of the series method of distribution:

Constant Factors:

1. Expenditure of E. M. F. (amperes).
2. Dynamo resistance.
3. Dynamo internal drop.
4. Line (conductor) resistance.
5. Line drop.

Variable Factors:

1. Number of translators (and hence resistance).
2. Resistance of individual translators.
3. E. M. F. generated.

It will be noticed that in the above summary I have stated that the resistance of individual translators is variable, though in the diagram it has been assumed to be constant in order to simplify the illustration.

The action of a series electrical system may perhaps be better understood by noting the very general analogy which is afforded by a system consisting of a hydraulic pump and

water wheels connected by a closed pipe so as to form a system in which a given quantity of water circulates perpetually. Whenever work is done by turning the pump, and thus producing a difference of pressure between the receiving and the discharging side of the pump, the water will circulate through the pipes, and thus transmit in the form of pressure the power which drives the pump, to the wheels, where the energy of the pressure will be re-converted into useful mechanical motion.

Such a form of apparatus is illustrated in Fig. 2, where the pipes are assumed to be made of glass. Tubes arising from several points in the circulatory system (as for instance from the upper or high pressure side of the pump at *A*, also from the pipe *B* beyond the first wheel, also from a point *C* on the pipe beyond the second wheel, and at *D*, representing the level of the return pipe) will show the water standing at the same level in all the pipes while the apparatus is at rest, as indicated by the line of equilibrium  $L^0$ , in the left hand diagram. When, however, the pump is rotated, the water will stand at different levels in the different tubes, as illustrated in the right hand diagram, ranging from a high level,  $L^1$ , at the high pressure or discharging pipe of the pump *A*, gradually dropping at  $L^2$  and  $L^3$  in the tubes *B* and *C*, as it passes through successive wheels, losing some pressure at each wheel, to a low level (indicated by  $L^4$ ) at the return pipe where the tube *D* is attached, when all or nearly all the pressure due to the action of the pump has been expended.

The difference of level between the highest and lowest points (*A* and *B*) indicating the total drop in pressure (neglecting the small drop in the return pipe), will represent the available pressure for distribution and for useful work, corresponding to the potential difference or voltage in the electrical system of Fig. 1. In case all the wheels were close to the pump, no perceptible loss or drop would occur in transmission from the pump to the first wheel, or between the wheels, or in the return pipe. The product of the difference of pressure between a point above and a point below one of the wheels, multiplied by the volume of flow (which indicates the rate of expenditure of such pressure) is the measure of the energy expended in operating each of these useful devices. Any break in the pipe or interruption of one motor stops the action of the whole system.

Thus illustrated, we conceive of electricity as completely filling the system of generation, distribution and translation, whether it is moving or at rest. We neither create it nor destroy it, any more than we create or destroy the water in the pump system; we simply start the dynamo and thereby disturb the equilibrium of the electricity which we assume pervades the whole system, and we thus give it pressure or head. This pressure results in motion or current (so-called); and this pressure is expended (or as we say, a drop is produced), at every point in the entire circuit in proportion to the resistance which the pressure encounters, some of it being expended in "internal drop," that is, in the generating mechanism, some in "conductor drop," and a large percentage (in a well organized system) in useful "work" by the translators. The same current which starts out from the dynamo returns to it after being deprived of its pressure to receive another charge of energy and start again to repeat its work. The "work" expended in the translators, added to the "conductor drop," is equal to the difference of potential or "voltage" at the terminals of the dynamo, and this voltage multiplied by the "current" or rate of expenditure of the potential in unit resistance, shows the total energy delivered by the generator to the circuit. Any break in the conductor, or any accident to a translator (in the series system, which we are now considering) stops the action of all the devices in the circuit, and may interfere with the action of the generator. The electricity itself costs us nothing; the pressure is all we pay for.

A good illustration of what has proved to be perhaps the best method of effecting the regulation of a series dynamo is afforded by the well-known Thomson-Houston type of generator, shown in Fig. 3. Here the variation of total E. M. F. is effected by an automatic magnetic device which moves the brushes toward the point on the commutator which represents the highest E. M. F., or away from that point in accordance with the increase or decrease of the strength of the main current which circulates through the governing coil. With such a dynamo, capable of operating for example forty arc lamps in series, and thus delivering, a maximum voltage of about two thousand automatic regulation is secured between wide limits, usually from the full number of lamps for which the dynamo is made, down to about the voltage required for ten lamps and the connecting circuit.

The second method of electrical distribution, which I have called the multiple arc or simultaneous method, is accomplished by leading out from the terminals or brushes of the generator to any required distance, two conductors practically parallel with each other, and connecting between them, by parallel cross wires or electrical bridges, two or more translators so that a multiplicity of paths is created for the expenditure of the pressure, and all the translators at any time actively placed in these multiple branches receive simultaneously the proper voltage and a fraction of the total current delivered by the generator. Each translator is therefore independent of all the others.

This is the reverse of the series method, for in the series system (with a varying load) the proper total voltage varies directly as the number of translators and the proper current is constant; while in the multiple arc system (with a varying load) the proper total voltage is the constant, and the current varies directly as the number of translators. In this general statement contrasting the two systems, I have not made mention of the conductor drop, which for the purposes of this statement is an immaterial factor.

In the lower diagram of Fig. 1, a multiple arc system is indicated under three conditions corresponding with those of the series system which forms the upper diagram of the same figure. In the left hand sketch the spiral indicating the generator coils is much shorter than that of the series generator immediately above, illustrating that under ordinary circumstances the standard of voltage delivered by a multiple arc generator is much lower than that of a series generator operating the same number of translators. With two 50-volt lamps I have assumed the total E. M. F. produced by the dynamo to be 110 volts; the resistance of the armature, the outgoing conductor, and the return conductor to be 1 ohm each, while that of the lamps is the same as in the series system, 5 ohms each. But instead of offering a total resistance of 10 ohms, as in the series system, the two lamps in the multiple arc offer only 2.5 ohms; hence, in order that the same percentage of the total E. M. F. may be expended in the distributing conductors, the resistance of these conductors must also be greatly less than those of the series system having the same length. I have illustrated this idea by assuming that these multiple arc conductors have a total resistance of only 2 ohms instead of 20 ohms as in the series system. As each lamp requires 10 ampères, the total current is 20 ampères. Proper action of this system is indicated by a volt meter connected at a point on the circuit near the lamps through pressure wires, and showing to the dynamo operator the normal working conditions.

The middle sketch illustrates the re-adjustment of potential which happens when two more lamps are connected in multiple arc, and the total E. M. F. is not changed. Instead of increasing the resistance of the outside circuit (as was the case in the series system) this addition of lamps decreases it from 2.5 to 1.25 ohms, and consequently this lamp division of the circuit causes a less number of volts of the same total E. M. F. to be expended. The diagram shows that the pressure has dropped from 50 to 32 volts at the lamps, and this change is instantly indicated by the volt meter to the dynamo operator.

Regulation in this system consists in so increasing the total E. M. F. that the lamp voltage shall return to 50, and in the right hand sketch we see the conditions which exist when this result has been accomplished. The current has risen to 40 amperes, which is equivalent to saying that it has been restored to the normal standard of 10 ampères per lamp, but in these multiple arc cases it has not been necessary for the dynamo attendant to concern himself about the ampères delivered, but only regarding the volts supplied to the translators operating in parallel.

We may here summarize some of the peculiarities of the multiple arc method of distribution:

#### Constant Factors.

1. Available E. M. F. at translators.
2. Dynamo resistance.

#### Variable Factors.

1. Number of translators (and hence resistance).
2. Resistance of individual translators.
3. Dynamo internal drop (with varying load).
4. Resistance of line (conductor) with length in use.
5. Conductor drop (with varying load),
6. Current.

Such a parallel system of distribution may be made clearer by a second hydraulic analogue which appears in Fig. 4. Here each water wheel is assumed to require an amount of water equal to that supplied to each wheel in Fig. 2; hence the total volume of flow or current of water is three times

as great in this parallel system as when the same water is used repeatedly by one wheel after another. In Fig. 2 a triple pressure is expended in three equal fractions in but one channel. The mechanical energy necessary in Fig. 4 to maintain a low pressure expended in three different channels is the same as that required in Fig. 2 to maintain three times the pressure expended in one channel. In other words, the product of the three-fold pressure by the unit current required for the series wheels of Fig. 2 is equal to that of the three-fold current by the unit pressure required for the multiple arc wheels of Fig. 4, such pumps and pipes as are necessary for equal economy being assumed.

In the left hand sketch of Fig. 4 the system is shown at rest or in equilibrium, and the water in the various pressure tubes is at the same height  $L^0$ . The right hand sketch illustrates the difference in the height of the water in the pressure tubes  $E, G, F, H$ , when the system is in operation. This difference is partly due to the fall in pressure which occurs between the opposite ends of the same main pipe; for example, the tube  $F$ , at the end of the upper pipe more distant from the pump, shows a lower pressure  $L^2$ , than is shown by the tube  $E$  at the pump terminal,  $L^1$ , and illustrates a fall by friction in the pipe, which is analogous to the fall in the conducting wires of Fig. 3. The difference in the height of the water in the two right hand pressure tubes  $F, G$ , is the result of the fall of pressure from  $L^2$  to  $L^3$ , which occurs in doing the useful work of turning the water wheels. Any one of the wheels may be stopped by shutting its individual valve or gate, which action corresponds to the breaking of a branch wire in the electrical system of the lower diagram of Fig. 1, by which each translator is turned on or off. In case one wheel is disabled or its individual branch pipe is broken, none of the other wheels are affected. The pump is adapted to give a low pressure but to throw a large volume of water through the pipe which is materially larger than that of Fig. 2, and as is the case in the electrical system of Fig. 1, the action of the pump may be modified so that just the proper pressure is delivered to the wheels at all times.

The multiple arc arrangement has been used for many years. It has been said that it was even utilized by Prof. Moses G. Farmer in an experimental plant operated by him at his home in Salem, Mass., thirty years ago or more. So far as I know, the earliest publication which specifically describes this parallel arrangement was a French patent granted to M. de Khotinsky in 1875. Fig. 5 is a reproduction of two of the drawings of that patent, made more clear by the use of red lines for the positive and blue for the negative conductors and by arrows indicating the direction of the current. The incandescent lamps which are described in this patent are here shown as conducting strips connecting the positive and negative branch wires, and it is evident that the main current sent out by the dynamo divides itself between all the lamps or bridges of the system.

The lower diagram of Fig. 5 shows an arrangement evidently supposed by Khotinsky to be the equivalent of a circuit entirely of wire, in which the earth forms the return. Actual practice has shown that while this use of the earth and its connections is practical for such small currents as are necessary in telephone, telegraph and similar work, there are serious difficulties encountered when the larger currents of electric light and power systems are expected to find their way back to the dynamo without continuous metallic conductors.

Following along the history of development of the multiple arc method of distribution, it is interesting to observe what was proposed in connection with incandescent lamps by Mr. Lane-Fox, an English experimenter, and described in two British patents of 1878. Mr. Lane-Fox seems to have clearly appreciated the idea that in order to properly operate incandescent lamps it was desirable to supply them at all times with a practically constant voltage, and to connect them in multiple arc in order that they might be separately controllable. Thus they would avoid one of the difficulties of a series arrangement, which is that when one lamp is put out or fails to operate, it tends to break the entire circuit and thus stop the operation of all the rest. The idea of Mr. Lane-Fox was to arrange a network of positive conductors on the principle shown by Khotinsky in the second of the diagrams I have reproduced, so as to keep up a steady pressure from all points of these conductors to earth, and thus force through each translator connected from line to ground, such a current as its resistance would allow to pass. If he knew of Khotinsky's arrangements he doubtless appreciated the fact that no provision had there been made for reducing the output of current by the dynamo when lamps were extinguished, because Khotinsky set forth a means of intro-

ducing an equivalent resistance into any circuit whenever its lamp went out. Lane-Fox suggested an automatic regulation of the dynamo by a mechanism which governed the throttle valve of the steam engine which rotated its armature. Foreseeing that there would still be a probability of a lack of uniform pressure throughout a large system, by reason of the drop which would occur even in very large conductors, he also proposed to place at different points through the district, storage batteries which should be charged from the central station during times of small load, and discharged when the requirements of the increasing load had reached a predetermined point. By means of this automatic dynamo regulation and this reinforcement by storage batteries he thus attempted to secure constancy of voltage delivered by the dynamo to the circuit, and uniformity of voltage (at one lamp with relation to other lamps) throughout the entire area. While neither of these methods has proved to be desirable in practice, the disclosure of them at the date of his patents showed a remarkable insight into the subject of electrical distribution.

The next material step in advance was made by Mr. Edison and described by him in patents applied for in February, 1880. One of these was granted in Great Britain in August of the same year, and the corresponding United States patent issued in 1887. Fig. 7 gives diagrammatically an illustration of the connection of several dynamos in multiple arc to a single pair of "omnibus wires" from which the main conductors of the distributing system are taken. In this original arrangement preference was given to vitalizing the magnets of the main generating dynamos by means of a special excitor, the field of which was in its turn excited by a battery. Later experiments showed that the main dynamos might with equal success and greater convenience be excited each by its own armature. To the omnibus wires, or to any portion of the distributing conductors, by means of "pressure wires" coming back to the station, was attached a galvanometer, or a test lamp, or some other means of indicating when the pressure delivered to the system was at a proper standard. One of the great steps taken by Mr. Edison in the perfection of this comprehensive plan by which a greater or less number of dynamos might be connected or disconnected in multiple arc, and might supply through outgoing and return metallic conductors large numbers of translators, was a special construction of the dynamos. The cardinal features which made these dynamos successful for this use were the reduction of the armature resistance to an exceedingly low point with relation to the joint resistance of the translators and the distributing conductors; also the construction of massive magnets, excited to a moderate degree by a small amount of electrical energy, and in this condition capable of a marked increase or decrease of their magnetism by a small variation of the exciting current. It is now clearly understood that the combination of these features constitutes one of the essentials in a system of multiple arc distribution, and this combination, the reduction of the internal resistance and the adoption of magnets of great mass, was for some time recognized as one of the wonders of electrical distribution. Such advances quickly become matters of course, in the rapid advance of such an art.

The regulation of a voltage delivered to the translators by the Edison type of dynamo solved the problem of securing constancy of potential which Lane-Fox had seen to be an essential of multiple arc lighting. The question of relative uniformity had occupied Mr. Edison's attention even earlier than the publication of his comprehensive multiple arc plan. It was clearly outlined as a problem and a clear solution was indicated, in a caveat filed in the United States patent office in August, 1879. The method is outlined in Fig. 8, and consisted in the division of the territory to be covered into fractional consumption circuits, each separately supplied from the central station by conductors having no translators directly connected. Thus in a system so large that it would be impracticable to supply it from one end on account of the size of the conductors necessary to carry a large current over a long distance to many lamps, it became feasible to secure the proper standard of pressure at each of several different points distant from the central station, and to make the drop beyond those points from the nearest to the farthest lamp of each fraction of the consumption circuit, so small that each lamp would give practically the same light as every other. It also became possible to cover large areas by economical amounts of wire, because the drop which occurred between the dynamo and the nearest lamps might be made anything that the engineer might desire, without affecting the relative action of the lamps. In this

plan a pair of pressure wires was to be led back from each point or center of distribution and attached to a pressure indicator in the central station.

In this same caveat is disclosed a method of automatic regulation of dynamos for constant potential, which has been found the most reliable and satisfactory for many uses of any system ever proposed. This method consists in equipping each dynamo with two magnet coils, one of which, usually called the primary or initial coil, excites the magnet to a degree merely sufficient to deliver at its brushes the standard of pressure required by the translators before any load is connected to the conductors. This primary coil may be brought from a separate excitor or taken from the brushes of the dynamo itself as a shunt to the outside circuit. The other coil (wound in the same direction) is of coarse wire and connected in series with the translating circuit, so that all the current which is intended for the translators shall pass through it. Thus as a greater amount of current is demanded and sent through this series coil, an increasing magnetism is induced which is sufficient to maintain the voltage practically constant at the translators, by increasing the total E. M. F. to such an extent that the resistance of the armature and of the outside conductors may be overcome and a proper number of volts still be left for normal operation.

(To be continued.)

### Proceedings of the First Meeting of the American Academy of Railway Surgeons.

Held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.

(Continued from page 409.)

#### NOT A CASE OF "RAILWAY SPINE."

BY WEBB J. KELLY, M.D.

GALION, OHIO.

Professor of Surgical Anatomy and Operative Surgery, Ohio Medical University; Member National Association of Railway Surgeons; American Academy of Railway Surgeons; Ohio State Society of Railway Surgeons; American Medical Association; Ohio State Medical Society; North Central Ohio Medical Society; Crawford County Medical Society; Surgeon "Big Four" and Erie Railways, etc., etc.

Railway surgery without the spinal malingering would be like a ship in mid-ocean bereft of her sails and her rudder. It is a question too, if we would not all lose our jobs if he did not exist; although it is claimed that our employment is a matter designated as being for sweet charity's sake, the court records show that the charity part of it is very much similar to the church donation of a candidate for a political office—sort of a "cast your bread upon the waters" affair.

It has been my privilege to examine and assist in the caring for many cases of spinal injury, and I might add, numerous cases of "supposed spinal injury." Out of the list, I wish to call your attention to four cases that have seemed to me to be very interesting, inasmuch, as they pretty well cover the different forms of injury sustained by the spinal column, namely, fracture without displacement, complicated with severe injury to the soft parts, resulting in recovery; apoplexy of the spinal cord, resulting in death; fracture with displacement, resulting in death; fracture and dislocation, resulting in good recovery.

*Case 1.*—S., aged 19; Irish; scrofulous; has had large abscesses on both sides of the neck; no history of syphilis, either hereditary or acquired; not an employee of the company. Please remember this.

In attempting to step on the front end of a moving switch engine, he misjudged the distance and went under the engine, being rolled between the front trucks until the engine could be stopped, which was probably a distance of thirty feet.

Examination a few minutes after the accident occurred revealed a comminuted fracture of the right forearm, about two inches above the wrist; contusion of inside of left foot; dislocation backward of left hip, with fracture of the acetabulum; the spinous processes of the lumbar vertebra were simply crushed flat, with slight curvature of the spine to the right. The soft parts over the lumbar and upper sacral region were badly contused and fairly bagged with coagulated blood. There was no paralysis of the motor or sensory nerves affecting either the limbs, bladder or rectum. The case progressed nicely. The coagulated blood was taken up, and with the exception of the deformity resulting from the hip injury, he is as well as ever. This would have been a typical case of "railway spine" had not the patient been wholly responsible for the accident.

*Case 2.*—H. T., aged 36 years, well developed, strictly temperate. July 3, 1880, his carriage was struck from behind by a runaway team, and he was thrown a distance of thirty feet, alighting on his head and shoulders. In company with my father, Dr. H. R. Kelly, I saw the case one hour after the accident occurred. He was conscious, and had been ever since the accident happened; there was a large scalp wound of the posterior part of the head, but no indentation of the bone; complete paralysis of the lower and partial paralysis of the upper extremities. The paralysis of the lower was of both motion and sensation, and was entire; that of the upper was only partial, and was more marked upon the right than upon the left side. There was also very slight paralysis of the intercostals. Failed to find any fracture or displacement of the vertebræ. However, about the seventh cervical there was some tenderness and a slight amount of ecchymosis. He suffered very little pain, in fact all the pain he had was occasioned when his head was considerable elevated. Diagnosed the case as one of apoplexy of the spinal cord, and the prognosis unfavorable.

Dr. Rosenthal, in his excellent work on "Diseases of the Nervous System," in speaking of apoplexy of the cord says: "Consciousness, speech and the functions of the special senses are frequently unaffected. It is only in abundant hemorrhages of a rapid course, and especially in those of the cervical region, that momentary loss of consciousness occurs. The paraplegic limbs most frequently also lose their sensibility. The anesthesia usually extends upward to the upper half of the back and of the abdominal region. Reflex excitability is preserved or even increased at the beginning, but it rapidly disappears when destruction of the cord occurs in a transverse direction, and especially in the gray matter. The paralysis also involves the sphincters; retention of urine and constipation occur in the beginning, but are soon followed by involuntary evacuations. The muscles which are insensible to mechanical stimulation and to the will, have also lost their electrical contractility. Cline has observed this abolition of muscular excitability upon the very day of the attack. Bed sores and erythema make their appearance. When the fatal termination is delayed, it is caused by progressive extension of the paralysis, by abolition of the vegetative functions, by bed sores, cystitis, pyelitis, and the final febrile exacerbations which accompany these complications. The duration of the disease may be counted by hours, weeks, or even months."

July 4. Found him in about the same condition to-day as yesterday. He has not evacuated his bladder. As he suffered a rupture of the urethra about a year ago, we at once attempted to pass a rubber catheter but failed. We then tried several catheters but were unsuccessful. The stricture had closed down very tightly, and there also seemed to be a curve in the canal through which it was impossible to pass anything. Being afraid of wounding the paralyzed urethra, we desisted and left him until the following morning.

It was now nearly forty-eight hours since his bladder had been emptied, and as we were again unsuccessful in introducing a catheter, we thought it best to resort to aspiration. The needle of a Dieulafoy aspirator was plunged into the bladder about two inches above the symphysis pubis, and about two quarts of urine withdrawn. The operation was an entire success, as not a single bad symptom followed.

We succeeded next day in breaking through the stricture with a No. 8 Van Buren and Keyes' silver sound. After which a catheter was successfully introduced, and his wife, who, I think, was the best nurse I ever saw—was able to catheterize him from this on. Once in a while the parts would become more relaxed, at which time there was a continuous dribbling of the urine, and at these times his sphincter would become very much relaxed. Although we were very careful with his bedding a large bed sore made its appearance over the sacrum. It was surprising with what rapidity these paralyzed parts sloughed out. He remained in this condition until August 13, when he was taken with a severe chill followed by a high fever. His friends were very anxious for counsel and Dr. Hamilton, of Columbus, was sent for. After carefully examining the patient, he was unable to give any hope for recovery. Patient remained in about the same condition until September 23, when he died. On account of the great sloughing, nearly every one of the lumbar vertebræ and the sacrum were exposed to view. Until the second day before his death, there had been no operation of the bowels for sixteen days.

*Necropsy.*—Twelve hours after death, in company with Dr. Ridgeway we examined the vertebral column and his spinal cord with the following result: Beginning at the cervical region extending to the first lumbar, we were unable to

discover any fracture or displacement of the vertebræ. The membranes were found to be in almost normal condition until we came to the eighth dorsal, where they became very much thickened and hardened. When the membranes were divided and the cord itself exposed, a different state of affairs was found to be present. Beginning with the first dorsal and continuing throughout the whole length of the cord, it was found that there had been complete degeneration from the first to the fifth dorsal, the gray more than the white, and more upon the right than the left side. The cord was so soft that we were compelled to be very careful in handling, lest we might not be able to finish the examination. From the fifth dorsal to the terminus it was very hard and when cut open gave that characteristic sound produced by cutting a scirrhus cancer. About the third or fourth, and also at the seventh dorsal vertebræ, were evidences of a hemorrhage. These spots were distinctly marked. As we were not prepared to examine the specimen microscopically, this was all that we were able to learn from the examination.

Although this case, strictly speaking, was not one of railway injury, it was just such a case as might occur at the time of a collision.

*Case 3.*—F. M., aged 36 years; German; switchman; moderately good habits. In attempting to get on back end of switch engine, the hand hold pulled out and he went under the engine. The engine was stopped as soon as possible, when it was found necessary to uncouple the tank from the engine to get him out, as he was wedged in back of the fire box. I saw him a few minutes after the accident occurred and found the following symptoms:

Complete paralysis of both sensation and motion below the dorsal region; complained of sharp pains and tingling sensation extending to soles of feet. Examination of spinal column revealed an apparent separated condition between last dorsal and first lumbar. The first lumbar seemed to have a fracture extending through the body, causing some compression from the left side. I use the term, seemed, for the reason that the fracture was not perfectly plain. The last dorsal was dislocated forward. The space intervening between the vertebræ was the width of the thumb. The case progressed from bad to worse, cystitis in an aggravated form starting up about the third week. The limbs became edematous. Ulcers formed over the sacrum, thighs, calves of legs, and the feet themselves almost separated from the body. The man lived for several months, finally dying from sheer exhaustion, after wasting away to a mere skeleton.

A post-mortem examination was not permitted, as the family desired to bring suit for damages, which they afterwards did, recovering something like four thousand dollars.

*Case 4.*—This case came under our care while I was absent from the city, and I am indebted to Dr. H. R. Kelly for the early history. T. N., aged 23 years; engine-wiper; good habits; formerly farmer. Was down under engine wiping when hostler attempted to move the engine. He was doubled up and wedged under the engine in such a way that it was almost impossible to get him out without jacking up the engine. Examination revealed a dislocation backward of last dorsal vertebræ, the deformity being fully one-half inch. The first lumbar was fractured through the body. There was paralysis of the motors below second lumbar nerve roots, which affected the bladder and rectum to a certain extent. The sensory system seemed to have escaped. It was necessary to use the catheter for about three weeks; very little dribbling of the urine, however, ensued. Great difficulty was experienced in moving the bowels. The knee jerk was present. The case progressed favorably and at the end of several months he was able to get around some. At this time, some ten years since the accident, he is able to work at the carpenter trade. I find pronounced lateral curvature which is so distinct that it is noticeable even when he is dressed for the street. The gait is straddling and labored. The sensations are good, and I am told his only difficulty is in locomotion.

This, gentlemen, is a brief history of four cases that have interested me, and I hope will call forth the experience of many other surgeons. The treatment has been purposely omitted in these cases, as it was the intention to show only the symptoms in certain conditions.

#### DISCUSSION.

DR. MILTON JAY, of Chicago—Any surgeon who has had much to do with railways for any considerable length of time must have had some injuries that involved the spine. To the railway surgeon the name of "railway spine" is a deep term, and I believe it is no longer used, for the reason that

it is made to cover all injuries of the spine up to traumatic neurasthenia. It is easy enough to give a name, but to determine the exact condition of an injury to the spine is frequently exceedingly difficult, and it requires a high order of skill and of scientific attainments to accurately diagnose spinal injuries in the majority of cases. We can have as many different kinds of spinal injuries as of any other organ of the body. We may have injury or involvement of the posterior or lateral columns of the cord. Nowadays a knowledge of physiology and of the pathologic conditions will enable us to determine whether or not the spinal cord is injured. If there be complete paralysis of any part it is positive evidence that the cord is injured, or else there is compression of the cord either by an effusion of hemorrhage, cerebro-spinal fluid or by compression of bone. I believe it is the duty of railway surgeons, when there is anything like paralysis of the spinal cord, to investigate very closely at the seat of injury, provided that injury has been along the spinal column, to know if the compression consists of a depressed portion of the vertebræ. If so, it is good surgery to elevate the depressed portion; I do not care whether it is the lamina, the transverse or spinous processes. If absolute compression exists, the paralysis can not be relieved until the depressed fragments are elevated. If there is an effusion, tap it. If the spinal cord itself is injured, that ends the case. The spinal cord, when severely injured or torn asunder, presents a condition that we can do nothing for.

As railway surgeons, there is nothing that is probably of so much importance as the medico-legal aspect of spinal injuries. Out of twenty cases of lawsuits brought to recover damages from railway injuries, fifteen of them will claim to have sustained injury to the spine, even if the spinal cord has not been touched. In these cases we should make a careful scrutinizing examination, using the battery with a view to testing the presence of the jerks and reflexes, or the absence of any of them. These examinations should be made as early as possible, and the railway surgeon should be prepared when the trial takes place.

DR. REGER—I infer from what has been said that in those cases in which there is paralysis after injury to the spine that they never fully recover their functions. I had a case two years ago of a young man who finding that he was going to fall, jumped off from the top of a rapidly moving train and fell with such force that it necessitated amputation of the right leg. The bones were driven through the soft parts. Paralysis of the lower extremities accompanied it—I mean paralysis of motion, but not of sensation. Any artificial motion would produce the most agonizing pain in his case, yet he did not appear to move a single toe. There was a perpendicular fracture of the first two lumbar vertebræ, and the displacement was almost the fourth of an inch. I could feel it distinctly. He was a very lean subject, and after the amputation of that limb I supposed the case would go on from bad to worse until he died. I applied a couple of narrow padded boards about four inches long to each side of those vertebræ, so that the weight of his body would press the parts together, and applied a plaster bandage over the parts. About four weeks after that was done he began to move the toes of the left foot. He kept on moving the limb, and continued it for over a year, and finally got entirely well. I suppose in this case it was simply an effusion that pressed upon the cord, and that no part of the bone had touched the cord or its membranes.

DR. JAY—Where was the fracture?

DR. REGER—The first and second lumbar vertebræ.

DR. HARNDEN—I have an idea that this subject is pretty well threshed out, and that I can add very little to what has been said, but I wish simply to call attention to one quotation which I made in my paper, that of Dr. Pope, of a collec-

tion and tabulation of 120 cases of spinal injury, in which 99 out of this number, he said, were tinged with the coloring of imposition. I think the subject has been very thoroughly handled of late; it is still engaging the attention of the surgical world, and I believe the more we study this subject the more will it be demonstrated that this element of imposition or fraud is a powerful factor in these cases, and that we should as railway surgeons study to eliminate this element as far as possible. During the war, through some method or process, I know not what, we killed off and buried out of sight the whole element called general debility. We have not heard of it in recent years, and I think now through an evolutionary process we are going to kill off the neurosis called "railway spine." Probably Erichsen never did a more foolish thing, or one which will dim the luster of his renown in the ages to come, so much as the one thing of inventing the term "railway spine." No physician uses it by itself today. I think, beyond any question, that the railways will be greatly benefited through the efforts that have been made by railway surgeons during the past three or four years to illuminate this mysterious subject. I think it is the common experience of the medical gentlemen present to meet with this bugbear in their private practice. A man or woman falls down on a slippery sidewalk, and has prospective damages in view against the corporation of the city. Immediately follow the symptoms, which are developed as a general thing by auto- or hypnotic suggestion or otherwise. The patient will complain of pain in the back, which is the primary symptom usually met with, and although he does not strain the ligamentous attachments of the spinal column or at any rate, the muscles of the back, the lumbar muscles, or otherwise, yet that symptom is of importance, developing into something tangible. It is our duty in railway injuries, especially as surgeons in attendance upon these cases, to be on the alert, to be cautious and quick to detect the incipient symptoms of this "spook."

DR. SCOTT—This paper should have brought out, I think, more discussion in regard to genuine injuries of the spine, and I only wish I were better prepared to discuss it. We must not lose sight of the fact that we do have genuine injuries and serious ones of the spine; that many of them are fatal within a short time. Many of them produce permanent injury, and the Doctor has given us reports of some cases of that character. I have found in my State among railway surgeons that there is a tendency, whenever they run across an injury of the spine, to throw it off and class it among those cases which have been under discussion so much in railway organizations during recent years, and in many instances overlook actual injury to the spinal column or to the spinal cord. We must remember that injuries to the bones of the spinal column, injuries to the ligaments, muscles and membrane are not uncommon, and I think that we should certainly give them due attention. I remember a case in point that I had a little over a year ago, of a man who was struck in the spine in the center of the dorsal region by the drive rod of an engine. The engine was running backward at the time. I thought from appearances he was suffering from a contusion, but shortly after paralysis developed, very much as that described in some cases of concussion of the spine. I was inclined to think, on account of some remarks the man had made, that he was assuming these symptoms of paralysis, but I afterward found that he was not doing so. He finally developed spondylitis. I was fully convinced that here was a genuine injury. I believe such a mistake is not uncommon among railway surgeons. We should remember that in these genuine injuries of the spine the prognosis is not always grave. A man will recover every now and then from a fracture of the vertebræ. They not infrequently recover from the effects of hemorrhage within the spinal canal provided the hemorrhage is not within the spinal cord itself. I do not believe there are any authenticated reports of cases of hemorrhage within the spinal cord where recovery has followed, that is, where it is within the tissues of the spinal cord; but from hemorrhage and effusions within the spinal canal between any of the membranes, we have every reason to believe that recovery takes place and it is not infrequent. I can recall two or three instances of complete paraplegia where recovery resulted, and where I had reason to think the paralysis was due either to hemorrhage or to effusion.

Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE . . . . . \$5.00

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MARCH 23, 1895.

AMERICAN MEDICAL ASSOCIATION.

In an organization like the AMERICAN MEDICAL ASSOCIATION, some one is always disturbed. A certain number find great fault with the JOURNAL, others are alarmed at what they call the political ring rule, and others think the ASSOCIATION ethics is a most serious rock of offense. Personal criticism of its officers and managers, is common ground for the display of disappointments and all the various slights and offenses, real and imaginary, that may appear. This is the friction that is a part of all organized movements, and indicates growth and progress which is always very promising for the future. The mutual admiration societies who never differ, who have no conflict of opinions on any questions, rarely accomplish anything for scientific medicine. Societies in which there is no struggle to become leaders or to direct its interests have not much influence in the world. In all live aggressive organizations there is a struggle, a restless movement and constant conflict, in which personalities clash and differ widely, but such differences are simply different points of view, which vary incessantly. This is no reflection on the honesty of the men who may be on opposite sides at different times, but evidence of their independence in thought and act.

To refuse to join the AMERICAN MEDICAL ASSOCIATION because of its ethics or want of ethics, or politics, or rings, or dislike of some one prominent in its management is childishness. The ASSOCIATION is not the product of any ring, or political or ethical standard of faith; it is the representation of American medical science; and of its progress and development. This is not to be measured and marked off from year to year, but to be estimated as the results

of years of history. The apparent ring rule of one year disappears the next, the battle over some question of ethics or rule of organization dies out the year following, or appears in some other question and so on, year after year, growing less and less personal, and more and more as a display of restless pent up energies.

The ASSOCIATION goes steadily on, and the solid conservative rank and file keep along undisturbed. Revolutions and sharp innovations are voted down, until the time comes for their free acceptance and indorsement, as the full consensus of opinion by the profession at large. Ambitious men may form rings for their personal advancement, but the soil is unfertile, and the yearly changes of the ASSOCIATION meetings bring new surroundings and new circumstances that are fatal to long success.

This is common every-day history of many other associations and organizations, and even of the church. To refuse to join an association because its members differ with each other in minor matters is weakness, To join and take active part, and defend convictions on all matters where differences exist, is manly and scientific. The science of medicine is not advanced and the great truths of nature evolved, by pharisaic criticism and refusal to take part in the struggle that every live society is passing through.

The AMERICAN MEDICAL ASSOCIATION is *National*, and belongs to the entire profession over all the country. If it is faulty in its management, its members are the real sinners. They are the powers who can control; they can unite and regulate any wrong that may exist; the officers and managers are but servants doing their bidding. Sneers and criticisms and refusals to join the ASSOCIATION because of this or that, are absurd and unreasonable.

The ASSOCIATION will go on, and its JOURNAL will appear regularly, entirely irrespective of the opinion or life of any individual. It is organized for the benefit of every medical man, and through its JOURNAL to bring him in touch with every advance of science, and with the work of the great teachers of the world. Its work and influence belongs to all alike; the practical country doctor, and the theoretical professor meet on the same level, and have equal voice in the control of the ASSOCIATION. It should be a source of pride to every physician that he belongs to the NATIONAL ASSOCIATION, and has a part in the growth and progress of American medicine which is destined at a not very distant period to lead all the world. It should be both a pleasure and duty to attend the meetings, and take part in the many questions which are presented in both the sections and general meetings. The larger and more widely extended its membership the more valuable its meetings become. It is from the opinions of physicians from widely differing sections of the country, that

great truths are evolved. The discussions which follow the reading of papers often contain far more truth and practical suggestion than elaborate textbook chapters. Many of the papers read are the most advanced studies of original workers, far beyond the teachings of the last book.

This ASSOCIATION was not established for any one class of men; it is for all, and its central purpose is to gather and organize the active workers in every department of medicine, and to create interest and sympathy in every new advance of science. It can not represent the views of any one man; it must reflect the opinions of the entire profession. It is a tribunal to which any member may bring his opinions for test and comparison, and may sit in judgment on the views of others. It is literally the final court of resort for medical men, and should be most enthusiastically supported by every practical student of medicine.

#### SUNLIGHT AND FRESH AIR.

So much attention is just now being paid to the prevention and restriction of tuberculosis, and so sweeping and radical are the measures advocated by those who would "stamp out" the disease at once, that it may be well to pause and try to find out "where we are at." The application of the tuberculin test to every bull, steer, cow, calf and heifer between the Atlantic and the Pacific oceans, as is urged by some enthusiasts, may prove to be no more necessary than the proposed notification of every case of tuberculosis and its suppressive or preventive treatment, as though it were as bad as leprosy or smallpox or worse than syphilis. Indeed it is questionable, as has already been intimated in these columns,<sup>1</sup> whether the wholesale tuberculin test may not be as mischievous in its results as the evil it serves to develop—whether it may not fan into flame a general tuberculosis from a latent spark which otherwise might have remained harmless.

Much good, however, is undoubtedly resulting from the attention given to the etiology of the disease and its infectious character, and among the most interesting and important of recent results, from a practical standpoint, are those accruing from the researches of DRs. SHERIDAN DELAPIN and ARTHUR RANSOME of Owens College, Manchester, Eng., the former Professor of Pathology, the latter Professor of Public Health in that institution. These gentlemen have for some time been pursuing an inquiry into the value of the municipal methods employed for disinfecting rooms in which tuberculous patients have lived, as well as into other methods of disinfection and the influence of certain natural agents on the virulence of the *B. tuberculosis hominis*. One of their reports was presented to the Scientific Grants

Committee of the British Medical Association shortly before the last annual meeting of the Association, but has only recently been published. It embraces fifteen elaborate tables, with illustrations, diagrams and text, dealing with the virulence of fresh human tuberculous sputum, the virulence of recent cultivations of the human and avian tubercle bacilli, the effect of drying on the virulence of pure cultures of the same, the action of euehlorin on tuberculous sputum and on cultures of the bacillus, the effect of sulphurous acid, of the soluble products of combustion, of chlorinated lime solutions, of ventilation and of sunlight on the same.<sup>2</sup>

Aside from the numerous experiments which have been made for the purpose of testing the virulence of the tuberculous products used in the experiments, and the influence of collateral factors, such as dryness, ventilation, heat, etc., the investigators conclude that:

1. The disinfection of rooms which have been contaminated with tuberculous products can not be obtained by means of the fumigation methods such as are generally used at present. Sulphurous acid, chlorin and euehlorin, as used under supervision by experienced municipal disinfectors, have proved practically useless. This only confirms the results obtained by KOCH and his pupils in the case of a number of other organisms.

2. The only other method of disinfection which seemed to promise more satisfactory results was the direct application of a solution of chlorinated lime to the walls to be disinfected. This method has given so far satisfactory results, but is attended with discomfort on the part of those who have to carry out the disinfection. It must be remembered that the experiments of SCHILL and FISCHER are unfavorable to the use of perchlorid of mercury.

3. Light is, in the case of the tubercle bacillus, as it has been proved by several observers to be in the case of other organisms, the most important natural disinfecting agent.

The bases of this last conclusion are to be found in Tables XIII—"Effect of Sunlight on the Virulence of Tuberculous Sputum," and XIV—"Effect of Sunlight on Pure Cultivations of the *Bacillus Tuberculosis Hominis*." In the former are given the results of specimens of four different sputa used in experiments on nine guinea pigs, from one-eighth to one c.cm., being injected subcutaneously into the tissue of the leg and into the peritoneum; all the sputa were proved to be infectious in control experiments; the specimens injected were previously exposed to sunlight and air for varying periods—the maximum being during "three bright afternoons"; one of the animals was killed and examined on the fourth, two on the seventh, two on the twenty-second, one on the thirty-seventh, one on the forty-sixth, one on the eightieth and one on the eighty-sixth day after injection. In none was any trace of tuberculosis found. Table XIV gives the results of similar experiments with a pure culture of the

<sup>1</sup> JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, p. 335.

<sup>2</sup> For these tables, etc., see British Medical Journal, Feb. 16, 1895.

bacillus—four guinea pigs being inoculated each with one-half c.mm., of a culture proved to be virulent by control experiments; the culture injected had been previously exposed to sunlight for a maximum period of eighteen and a half radiant hours; the first pig was killed and examined on the forty-third day after inoculation, the remaining ones on the seventy-eighth, one hundred and fortieth and one hundred and fiftieth days. In none was any trace of tuberculosis found.

Do not the results of these painstaking and elaborate investigations tend to show that the radical measures of chemic disinfection, of segregation, of branding and labeling the unfortunate tuberculous are wholly uncalled for or worse? Do they not again demonstrate the sufficiency of the great natural agents of disinfection—sunlight and fresh air? And may not all necessary prophylactic measures in the family of a consumptive patient be safely left to the attending physician, without the intervention of the health officer or municipal disinfecter?

#### A PITFALL FOR THE PROFESSION.

One of the most largely attended meetings of the New York County Medical Society was held last week at the Academy of Medicine in New York city in response to the following call:

WHEREAS, A number of instances have occurred in this city where reputable members of this Society have been arrested for complicity in malpractice cases without even the shadow of a reason for such action on the part of the police; therefore, we, the undersigned, respectfully request you to call a special meeting of the Society for the purpose of ascertaining the rights and privileges of physicians who may be called to attend cases of abortion, etc.

The immediate occasion of this call was the recent arrest of two reputable physicians, members of the Society, who had been summoned to a patient in the house of a midwife, and to whom the patient represented that she was a widow and denied absolutely that any operation had been performed on her or any medicine given to her. The physicians ordered her taken to a hospital, having previously sent for a coroner, who could not be found before it was necessary to remove the woman. She died in the hospital after making a full confession, incriminating the midwife and completely exonerating the physicians; notwithstanding which they were arrested by the police and taken before the coroner, who refused to hear them, and was about to hold them in \$5,000 bail each when, on the intervention of a coroner's physician who knew them, they were released on their own recognizances. The jury, made up of medical men, returned a verdict that the attending physicians had acted in every respect in accordance with their duty.

DR. E. H. GRANDIN, President of the Society, on calling the meeting to order, said:

"An indignity has been imposed upon the medical profession by the police, and their action in a recent case, which may form a precedent unless a protest is made. We find ourselves between the horns of a dilemma. When called to the bedside of a dying woman, if we do not respond we lay ourselves open to the imputation of inhumanity. If we do respond and find the woman in danger from what appears to be the result of a criminal operation, we must take one of two courses: Either report the matter to the police and subject ourselves to the possibility of a libel suit, or keep it secret and, in the event of the death of the patient, run the risk of arrest. We are here to protest against the idea that the presence of a medical man at the bedside of a woman suffering from miscarriage is *ipso facto* evidence that he has committed a crime in the matter. It is the midwives and notorious abortionists who, under the guise of specialists, commit these crimes, for which they are so often indicted but so seldom punished. This crime is on the increase. Are the officers of the law, by their laxity where they should be most active, responsible for this state of affairs? This city should be made too hot to hold abortionists."

In the discussion which followed, Drs. JACOB, MARKS, REED, IRWIN, VAN RANDOHR, TUTTLE, HART and others, including the coroner himself, a Dr. HOEBER, participated—the latter gentleman announcing and attempting to defend the startling proposition that a physician is bound to reveal the secrets of the sick room where he may suspect crime has been committed. After a somewhat exciting session, a resolution was adopted instructing the counsel of the Society to furnish an opinion on the subject-matter of the call as therein recited, and a resolution, offered by DR. MICHAELMAS, denouncing the arrest of the physicians as unjustifiable, declaring that abortion is on the increase, and calling for legislation making it a criminal offense for any person but an M.D. to practice midwifery, was referred to a committee.

It is to be hoped that the Society will not let the matter rest in this stage. It is notorious that criminal abortion is rife in every large city; that the premises of too many midwives are simply slaughter-houses; and that it is the common practice of these hell-hags to shunt their dying victims off on to the nearest physician whenever it can be done. No general practitioner who does obstetric work in any large city of the country is safe in taking an emergency case without pursuing such inquiry as to make him subject to the charge of being inhuman and cold-blooded. The practice of midwifery should be, as DR. MICHAELMAS suggests, confined by criminal statute to regularly graduated physicians, and the abortionist-midwife be made an outlaw.

THE forty-sixth annual session of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

### THE NOMENCLATURE AND CLASSIFICATION OF DISEASES.

SURGEON-GENERAL STERNBERG has issued a revision of the nomenclature and classification of diseases in use in the Medical Department of the Army. Up to this time the official classification was practically that of the College of Physicians of England, and included many divisions and subdivisions such as zymotic, miasmatic, enthetic, zoögenous, etc., that belong to a past era in the progress of medical knowledge. The new classification is therefore a step in advance taken at the instance of clinical as well as etiologic considerations. The nomenclature used is simple and as free as possible from technicalities. Developmental diseases and the refractive errors of the eye find no place on the new list, as men with such disabilities should not be accepted for service. The dietetic class, which included alcoholism and results, delirium tremens, drug habit and scorbutus has been broken up, and scurvy placed among the general diseases of nutrition with acute alcoholism, chronic alcoholism, delirium tremens and chronic narcotic poisoning among diseases of the nervous system. The class of parasitic diseases is also omitted, scabies being placed among local infections of the skin, and trichinosis among infections. Rheumatic fever, carcinoma and sarcoma appear among the general infections. Their right to this position has not been established satisfactorily, but it is strongly indicated by the tendencies of recent etiologic studies. In order not to dislocate certain local infections too abruptly from their old associations they are entered under "structural and functional diseases of organs," as well as under "infections," so that in consolidating the statistics they may be thrown in either direction as desired by the statistician. Among many minor changes, hernia is placed with accidents and injuries where it properly belongs, instead of being included, as heretofore, among diseases of the digestive system. We will print the circular containing the list in this issue of the JOURNAL.

### DECISION REGARDING THE QUARANTINING POWERS OF BOARDS OF HEALTH.

The Health Commissioner of Brooklyn, Dr. Z. T. EMERY, has obtained through counsel an important reversal of a former decision that had the effect of abrogating the powers of health officers to practice quarantine for the purpose of stamping out smallpox and the like. This reversed decision is a virtually unanimous opinion of the three judges sitting in general term of the Supreme Court of New York, and can not fail to be far-reaching in its influence in all States where the legal system resembles that of New York. This probably includes not less than one-half of the United States. The judges sitting in this term

were JUDGES DYKMAN, PRATT and CULLEN. The decision was signed by the former two; the last named did not sign, for he was not present at all the hearings.

The reversal asserts that the Commissioner of Health has the right to order that persons may be quarantined for the protection of the health of the community, where a proclamation has been duly made that the public health is endangered by reason of impending pestilential disease, that it is the duty of the Board of Health to exercise a proper and vigilant control of persons and things which, from any cause, are liable to communicate contagion. The question of compulsory vaccination was not at issue in this case, and the reversal does not affirm or deny the right to compel that procedure in a direct way. The following are the closing paragraphs of the decision, freed from the technical legal references to authorities, enactments, etc.:

"These relators fell under the control of the Board of Health; they came to the city from infected places, and they were liable to communicate contagion; they were, therefore, proper subjects for isolation and they were quarantined and detained in their premises. That isolation and detention was clearly within the scope and powers and duties of the Board, and that is all it did. The Board did not require the relators to be vaccinated, and that seems to be the error into which the relators have fallen. They seem to assume that the Board of Health intended to compel them to be vaccinated, but the acts of the Board admit of no such construction. There was neither coercion nor compulsion. They were isolated and deprived of their freedom because they had been exposed to smallpox and were liable to be seized therewith, and by communication with others, to spread the disease. That was a legitimate exercise of the power and authority vested in the Board by statute, and it was unnecessary to prescribe any conditions upon which the relators could terminate their isolation; that was done entirely for their benefit and for no other purpose. If they availed themselves of the privileges tendered to them, their acceptance would terminate their quarantine, and their refusal would leave them in isolation until July 1, 1894, the time mentioned in the mayor's proclamation. They refused the condition and instituted this proceeding. The prevention of smallpox is of such paramount importance as to justify all reasonable means for its accomplishment. In the age of the world we live in, security is gained from the awful pestilence of smallpox by reason of the practice of vaccination as a preventive. Its efficacy has been recognized by physicians of all schools for nearly a century. Dr. JENNER, its discoverer, was immortalized by its introduction. Vaccination was accepted and practiced by the entire civilized world within six years from the time of its first discovery, and it has been in universal use from that time until the present. It is stated in the return, and the statement is uncontradicted, that it is a well established scientific fact that vaccination is a preventive of smallpox in the person vaccinated, and it has been for many years demonstrated that thorough vaccination of persons in crowded centers is indispensable to the prevention of epidemic smallpox.

"This statement, as we have narrated, is in accord with the advanced thought of the age in which we live, and it receives our concurrence. We have decided at the present term of this court that vaccination may be required as a condition precedent to the admission of children to the common schools of the City of Brooklyn.

"The propriety and wisdom of the course pursued by the Board is beyond criticism. Its acts have all been within the lines of statutory authority, and they have been discreet and in evident good faith in the presence of an impending pestilential danger."

**The Forty-sixth Annual Session** of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

## THE AMERICAN LANCET.

After twenty-four years' service in medical journalism, the veteran editor of the *American Lancet*, Dr. LEARTUS CONNOR has retired from responsible editorship, and the publisher announces that the publication will cease from and after the issue of the March number.

Under the guidance of Dr. CONNOR, the *Lancet* has been clean, bright, scholarly and fearless, and the tribute paid him by Mr. GEORGE S. DAVIS, the publisher, is only a just tribute to his worth and merit. In his valedictory the editor says:

"The *American Lancet* has done what it could to promote the advancement of the profession along the highest lines coincidentally with the marvelous changes in and out of the profession of medicine during the past twenty-four years. It has encouraged young men to acquire the art of writing, and old men to continue in the practice of this art, to the end that more facts and experiences of value might be placed upon the written record of the profession. It has encouraged medical society work and sought to multiply medical society workers. It has never neglected to encourage every effort for sound medical education along such lines as experience has shown to be the wisest. To repress the false and develop the true in all directions of the science and art of medicine and among medical workers, has been its constant aim."

## CORRESPONDENCE.

WILMORE, CAMBRIA CO., PA., March 19, 1895.

To the Editor:—Can any of the readers of the JOURNAL inform me of the name of the town in the State of Maine where Professor Usher Parsons was born (he being the first Vice-President of the AMERICAN MEDICAL ASSOCIATION), and if he was a descendant from Joseph (4th) Parsons and Elizabeth (Usher) Parsons, of Braintree, Mass?

There have been many of the Parsons family who have received the given name of Usher. Perhaps the youngest may be Dr. Usher Irving Parsons, of Council Bluffs, Iowa, who is now Professor of Physiology in the medical school of that city.

And can any one inform me about Dr. Hall Jackson, of Portsmouth, N. H., who must have been in practice during the latter part of the last century?

IRVING C. BLAISDELL, M.D.

ANSWER:—Dr. Usher Parsons was born in Alfred, York County, Maine, in 1788. For a notice of Dr. Parsons see Trans. Am. Med. Asso., Vol. XXI, p. 430. There is no notice of him in Thatcher, Williams, Gross, Atkinson or Stone.

## PUBLIC HEALTH.

**Praiseworthy Action of a Railway Company.**—A diphtheria corpse was recently shipped from Hammond, Ind., to Lima, Ohio, and thence to Spencerville, Ohio, where the body was interred. The matter was brought to the attention of the Chicago & Lake Erie Railway Company, over which line the shipment was made, and on a report from the health authorities the superintendent suspended the conductor, train and station baggage-masters who assisted in handling the body. It was found that the

shipment had been made as indicated and the rules of the State Board of Health and of the company violated, because the father of the child was connected in some way with the road.

**Demography of San Luis Potosi.**—The JOURNAL is in receipt of the current series of weekly bulletins, *Demografico-Meteorologico*, of the city of San Luis Potosi, Mexico, compiled under the direction of the Inspector General, Dr. J. E. Monjaras. The population of the city, by the census of December, 1891, is 68,401, composed of 31,919 males, 36,482 females; under 15 years of age, 24,855, between 15 and 60 years 41,444, over 60 years, 2,102. The deaths during the first seven weeks of 1895 were 373—an annual mortality rate of 40.5 per 1000. The *Boletin* makes no comment upon this high death rate which is in excess of the natality rate for the same period, during which only 362 births were reported—an annual rate of 39.2 per 1000.

**Sterilization of Milk.**—Rodet thus reviews in the *Bulletin Medical de Paris* the three principal methods of sterilizing milk by heat: 1, sterilization, properly so called, by a temperature of 110 to 120 degrees C.; this is the only way to kill all the germs and keep the milk for a long time; 2, pasteurization, or heating to the minimum of 75 to 80 degrees, which, while not affecting the most resistant microbic forms, nevertheless inhibits their pathogenic activity and retards the fermentation of milk; 3, the method between these two, of employing about 100 degrees of heat, is the one commonly used and its power of sterilization depends on the length of time it is carried on. Ebullition of the milk, even if short, acts powerfully against the pathogenic microbes and against the acid ferments. Among the drawbacks to sterilization is the brown color which some milk assumes and which offends the eye of the consumer, as well as changes its taste. These changes are of little importance compared with the pellicle which forms on the surface of milk boiled while exposed to the air. This imprisons a certain quantity of cream and hence affects the nutritive value of the milk. Its formation may be nearly entirely avoided by boiling in bottles in steam or boiling water, as in Soxhlet's method. According to M.M. Budin and Rodet the milk prepared according to the latter method possesses a value for nurslings at least equal to raw milk. For milk consumed in cities, the boiled or sterilized method possesses a greater superiority. Contrary to the opinion of certain authors, who attribute a less degree of nutritive value to boiled or sterilized milk on account of its greater digestibility, Rodet thinks that the difference, if any exists, is very slight.

**Prevailing Morbidity.**—The equable temperature of the past week, although below the normal in some regions, has favorably affected the seasonal diseases. Diphtheria in the larger cities has undergone a notable diminution in prevalence, but, as is common, its ravages in the rural districts and smaller towns are reported to be quite severe. The enthusiastic advocates of the antitoxin treatment still continue to attribute the decline to the new remedy; Dr. Herman Biggs, of the New York City Board of Health, is quoted as ascribing a reduction of 40 per cent. in the diphtheria mortality in that city to this cause.—The smallpox situation is substantially as reported in last week's issue of the JOURNAL. Sporadic cases continue to occur in many of the Northern States—St. Paul, Minn.; New Haven, Conn.—among the Yale students—at some points in Ohio and elsewhere; but its increase is mainly in the region south of the Ohio River. The reports are conflicting and, like the "fever and ague" of early days, there is none in the town making the report but in the neighboring town or some other locality, the disease is "raging." Quarantines continue to impede travel throughout the Valley States. Dr. Wingate, Secretary of the Wisconsin State Board of Health, reports, March 18, total number of cases on hand in Milwaukee, 18; in hospital 7, in homes 11; he also reports 5 cases at Sparta, in Monroe County. In Chicago, the Health Commissioner, Dr. Reynolds, is congratulating the community on its escape from the usual second year of the epidemic—citing the following comparative figures: In the last epidemic, 1881-83, there were 1,180 deaths during its first year out of a population of 540,000; in 1894, the first year of this epidemic, there were 1,033 deaths among three times the population; in January,

1882, there were 345 deaths; January, 1895, 55 deaths; February, 1882, 281 deaths; February, 1895, 30 deaths; first twenty days of March, 1882, 171 deaths; first twenty days of March, 1895, 19 deaths. He claims that the outbreak is substantially at an end.—Influenza fails to make any appreciable impress on the general death rate in this country, although its influence on acute lung diseases is quite marked.—What is probably an outbreak of epidemic cerebro-spinal meningitis is reported to be prevailing as a "fearful pestilence" in Floyd County, Kentucky, some fifty deaths being already reported among its sparse population. Dr. B. M. Smack, of Oakland, Ky., has been sent into the region to investigate, and his preliminary report to Dr. McCormack, Secretary of the State Board of Health, confirms the diagnosis.

In Europe, influenza continues to attract attention; the disease does not subside so rapidly as was anticipated, and the official figures of the last week show an increase in London, where the number of deaths from the malady for the first half of the month was 769; this exceeds the total for the entire year of 1894. The death rate of the city for this period reached 41 in the thousand—one of the highest points ever known. In Scotland the death rate in February was 45 per cent. higher than any previous February rate since records were kept. A special cable dispatch to the *New York Sun* says that "the influenza is peculiarly malignant in certain places. Three sisters died of the disease at Rochester this week, and it was necessary to postpone the funeral because all the mourners were prostrated by the same malady." From Berlin, reports indicate no decrease in the spread of the epidemic; there have been since January 1, 730 deaths from this cause in Berlin alone.—An outbreak of what is, apparently, the human form of the foot-and-mouth disease of cattle has appeared among the inhabitants of Schönberg, a suburb of Berlin, and physicians are said to be apprehensive of its spread throughout Europe. Dr. Thorne Thorne was the first to establish the transmissibility of this zöogenous disease to the human family through the milk of diseased cows and its transmissibility by direct contact is well-known to veterinary surgeons. It is hardly possible, however, that the cattle of Europe are so generally affected with the disease as to cause any wide spread of it in human beings. Professor Virchow and a committee of the Berlin Medical Society are investigating the local outbreak.

**Health Reports.**—The Supervising Surgeon-General of the Marine-Hospital Service has received the following health reports:

#### SMALLPOX—UNITED STATES.

Arkansas: Little Rock, February 1 to March 8, 82 cases; 14 deaths; Hollywood, Clark County, March 8, 1 case, 1 death.

Louisiana: New Orleans, March 2 to 9, 2 cases.

Michigan: March 1 to 9, smallpox reported at Detroit, Grand Rapids, Highland Park and Three Rivers; one case of suspected smallpox at Ypsilanti.

Ohio: Cincinnati, March 8, 12 cases, March 8 to 15, 3 cases, 1 death; Lima, March 1 to 8, 1 case, 1 death.

Illinois: Cairo, March 11, 1 case.

Tennessee: Memphis, March 13, 1 case, 1 suspected case.

Texas: Fort Worth, March 2 to 9, 4 cases; Marshall, March 13, 1 case.

Wisconsin: Dover, March 2 to 9, 4 cases; Milwaukee, March 2 to 9, 7 cases, 2 deaths.

#### SMALLPOX—FOREIGN.

(Reported by U. S. Consuls).

Arabia: Aden, January 26 to February 9, 2 cases.

Belgium: Brussels, February 16 to 23, 1 death.

Holland: Rotterdam, February 23 to March 2, 13 cases, 3 deaths.

Ireland: Dublin, February 16 to March 2, 166 cases, 11 deaths.

Gibraltar: February 17 to 24, 1 case.

India: Calcutta, January 26 to February 2, 43 deaths.

Italy: Naples, February 16 to 23, 2 cases, 2 deaths.

England: Leeds, February 23 to March 2, 1 case; Liverpool, February 23 to March 2, 3 cases 1 death; London, February 16 to 23, 75 cases, 1 death.

Russia: Moscow, February 9 to 16, 2 cases 2 deaths.

Scotland: Edinburgh, February 16 to 23, 1 case, 2 deaths; Glasgow, February 16 to 23, 40 cases.

#### CHOLERA.

Ceylon: Colombo, January 26 to February 2, 8 cases, 8 deaths.

India: Calcutta, January 26 to February 2, 28 deaths; Madras, February 2 to 8, 4 deaths.

Austria-Hungary: Galicia, (4 political districts) February 4 to 10, 11 cases, 7 deaths.

Russia: Petrikov Gov't., January 13 to 19, 2 cases, no deaths; Radow Gov't., January 6 to 19, 5 cases, 4 deaths; Suwalki Gov't., January 13 to 19, 8 cases, 7 deaths; Kurland Gov't., December 30 to January 12, 27 cases, 14 deaths; Podolia Gov't., January 13 to 19, 69 cases 37 deaths; Taurien Gov't., January 6 to 12, 26 cases, 19 deaths; Minsk Gov't., January 6 to 12, 5 cases, 3 deaths; Kursk Gov't., January 6 to 12, 3 cases, 3 deaths; Saratov Gov't., January 6 to 12, 3 cases, 1 death.

Turkey: Constantinople, January 29 to February 4, 46 cases, 22 deaths.

#### YELLOW FEVER.

Ecuador: Guayaquil, February 15 to 22, 2 deaths. The Consul-General at Guayaquil writes that "of the seven or eight men of ships' crews dying within the last ten days, none are reported as having died of yellow fever, while the common apprehension is that they all died of that pest. The ports of Peru are quarantined against Guayaquil."

Cuba: Havana, month of February, 4 deaths; March 1 to 7, 5 cases.

Under date of Jan. 18, 1895, the United States Consul at Amoy, China, reports the following relative to the existence of the plague in Amoy: "Several times last summer during the prevalence of the plague in Hong Kong and Canton, rumors came to me that isolated cases were occurring in Amoy. In every instance, however, prompt inquiry of the medical officers of the port, Dr. MacDougall and his assistant, Dr. Wingate, elicited the assurance that no cases of the plague were encountered by them, either in their general practice or in their Chinese hospital, and besides they had kept out a standing offer of a considerable reward for any such diagnosed by a foreign surgeon. But on January 5, I received official notification of the existence of the plague in Amoy, a limited number of cases having occurred. Some of these cases speedily terminated fatally; but the arrival of a Cantonese doctor was followed by good results in saving a large proportion of the patients; and in fact it is now said there are now no cases left in the town. I understand that the disease has made its appearance in the interior towns and villages to the north and west of this port, but of this I am wholly without reliable information."

The following letter has been received from Acting Assistant Surgeon L. P. Gibson, M.-H. S., at Little Rock, relative to smallpox at Hot Springs and vicinity:

"I have the honor to report as follows concerning smallpox in this State: At Hot Springs, the Secretary of the State Board of Health reports that there have been 115 cases and 26 deaths up to date. At Malvern, 4 cases, no deaths; at Donaldson, 4 cases, no deaths; At Hollywood, 1 case, no deaths. The disease has appeared at Brinkly, Ark., the crossing of the L. R. & Memphis with the St. Louis & Northwestern R'y. There are 4 cases with no deaths thus far. The large increase of cases at Hot Springs for the week does not represent the actual number of new cases for that period. A number of them are cases that existed before, but were not discovered. All the cases in this State are traceable to the same source of contagion, Hot Springs.

"Little Rock, Ark., March 16, 1895."

#### ADDITIONAL REPORT OF SMALLPOX.

England: London, February 23 to March 2, 68 cases, 1 death.

Scotland: Edinburgh, February 23 to March 2, 9 cases, 2 deaths.

Russia: St. Petersburg, February 9 to 16, 9 cases, 3 deaths.

#### ADDITIONAL REPORT OF SMALLPOX IN UNITED STATES.

Ohio: Columbus, March 9 to 16, 1 case.

## BOOK NOTICES.

**Suggestions to Hospital and Asylum Visitors.** By JOHN S. BILLINGS, M.D., and HENRY M. HURD, M.D., with an introduction by S. WEIR MITCHELL, M.D. Philadelphia: J. B. Lippincott Co. 1895. Price 50c.

An excellent book of conundrums which hospital visitors should propound to themselves on visiting hospitals, the answers to which are to be found in the conditions as they exist. Notwithstanding that the book has been compressed

into 48 pages, it seems to cover all the points necessary for hospital inspection. The book should be read by hospital stewards, hospital matrons, nurses, and internes, as well as by hospital visitors.

**A Manual of Bandaging**, adapted for self-instruction. By C. HENRI LEONARD, A.M., M.D. Professor of the Medical and Surgical Diseases of Women, and Clinical Gynecology in the Detroit College of Medicine. Sixth edition, with 139 engravings. Cloth, octavo, 189 pages. Detroit, Mich.: The Illustrated Medical Journal Co., Publishers. Price, \$1.50.

This is the sixth edition of this book, and is well worth examination and a place in one's library. The explanatory cuts are numerous, and the text lucid.

**The Anatomy of the Nasal Cavity and its Accessory Sinuses.** An Atlas for Practitioners and Students. By DR. A. ONODI. Translated from the Second Edition by ST. CLAIR THOMPSON, M.D., London, F.R.C.S. London: H. K. Lewis. 1895. Small quarto.

This book consists of a set of plates which show the topographical relations of the nasal cavity and its accessory sinuses. They represent sections made in different directions and photographic reproductions. The anatomic preparations were made in the laboratories of Mibalkovics and von Thanoffner in Buda-Pesth. The plates from 1 to 14 are extremely valuable. The rhinologists can scarcely afford to be without a copy of these exquisite plates. They are very instructive for general practitioners and students, as well as for specialists. We can not speak for plates Nos. 15 and 16, as by some inadvertence they have been omitted from the copy sent to the reviewer.

**A New Surgical Work.** A System of Surgery, edited by FREDERIC S. DENNIS, M.D., and JOHN S. BILLINGS, M.D.

This work is announced by Lea Brothers & Co. as shortly to appear, in three imperial octavo volumes. The list of contributors embraces the names of W. T. Bull, Charles McBurney, and Robert F. Weir, of New York; Councilman, Porter, Richardson, and Warren, of Harvard; Carmalt, of Yale; Keen, White, Roberts, and Wharton, of Philadelphia; Welch, of Baltimore; Park, of Buffalo; Conner, of Cincinnati; Mudd, of St. Louis; and Senn, of Chicago.

**Edwards' Hygiene with Anatomy and Physiology**, Being an Amplification of Edwards' Catechism. By JOSEPH F. EDWARDS, A.M., M.D. Intended for Schools and General Reading. Published by Edward B. Slavin, New York. No date.

It is a great pity that in a book designed for public schools the illustrations should not be more accurate than is the case with most of those in this book. The perspective of the picture on page 8, showing the disposal of organic matter, is bad; and the triangular liver, three-cornered heart and variously shaped intestines in another place would cause the ghosts of Vesalius and Gray to rise from their environment. Extremely ludicrous is the picture of a pugilistic encounter on page 45. Some of the schemes and diagrams are much better, but there certainly can be no excuse for the one on page 121. The text of the book is interesting, if somewhat allegorical and after the manner of fables wherein the good children are always rewarded and the bad are horribly punished. As a work of hygiene we have no hesitancy in recommending the general principles it teaches; as a work of art it is a lamentable failure, and we sincerely trust if the book reaches the dignity of a second edition the author will induce the publisher to have it more appropriately illustrated.

**Text-Book of Chemistry.** Intended for the Use of Pharmaceutical and Medical Students. By SAMUEL P. SADTLER, Ph.D., F.C.S., and HENRY TRIMBLE, Ph.M. Philadelphia: J. B. Lippincott Company. Pages, 950 octavo. 1895. Price \$5.

This book is of a much higher order of chemistry than is usually supplied to students and seems to be well calculated

for the uses and purposes of practical chemists. As a text-book for the use of medical students, it would perhaps be more convenient if the questions had been added as in some of the other works on chemistry, in order that the student might be able to grasp the full meaning and purport of the technical propositions contained in the text. Part I gives a brief outline of elementary physics. Parts II and III describe the elements as divided into non-metals and metals. Part IV deals with organic chemistry. Part V gives a brief outline of qualitative and quantitative analysis, and here original methods are described. A number of assays of the U. S. Pharmacopœia are also added. This book is one of the highest practical character, and while there is a good deal in it that the student of medicine will not particularly need in after life, yet it is well to have once known the methods of mineralogical analysis, even if it shall only serve as convenient pegs of memory on which to hang correlated scientific theories. For pharmacy students and chemists it leaves nothing to be desired.

**Elements of Pathologic Histology with Especial Reference to Practical Methods.** By DR. ANTOINE WEICHELBAUM, Professor of Pathologic Anatomy and Director of the Institute of Pathologic Anatomy in the University of Vienna. Translated by W. R. DAWSON, M.D., Demonstrator of Pathology in the Royal College of Surgeons, Ireland, etc., with 8 plates and a large number of illustrations in the text, some of which are colored. London: Longmans, Green & Company. 1895.

This book has been divided into chapters, English fashion, by the translators, and we find thirteen of them as follows: Chapter I follows an introduction of nine lines, and is devoted to histologic methods of investigation. Chapter II is divided into bacteriologic methods of investigation. Chapter I is divided into three parts, and Part II into six chapters covering the general pathologic histology as follows: 1, Retrograde Changes in Tissues; 2, Progressive Tissue Changes, Inflammation, Infective Granulation Tissue, Tumors; 3 and 4, Tumors or new Formations; 5, Parasites, which includes vegetable parasites, under which heading the Bacteria are included. Chapter VI, Animal Parasites, which includes the protozoa, sporozoa, infusoria, cystoides, trematoides, pneumatoides and arthropoda. Part III, Special Pathologic Histology, divided into thirteen chapters: I, The Blood; II, Circulatory Apparatus; III, The Spleen, Lymphatic and Thyroid Glands and Suprarenal Capsule; IV, Digestive Apparatus; V, Liver, Bile Ducts and Pancreas; VI, Respiratory Apparatus; VII, Urinary Apparatus; VIII, Generative Apparatus; IX, Nervous System; X, Organs of Locomotion; XI, Skin; XII, Eye; XIII, Ear.

The book is beautifully printed; the paper is excellent; the illustrations all that could be desired. The book contains the latest investigations on the subject of which it treats and will repay the most careful study. The photographs of various bacteria, which are shown at the end of the volume, are extremely handsome.

**Manual of Chemistry.** A Guide to Lectures and Laboratory work for Beginners in Chemistry. A Text-book specially adapted for Students of Pharmacy and Medicine. By W. SIMON, Ph.D., M.D., Professor of Chemistry and Toxicology, College of Physicians and Surgeons, Baltimore; Professor of Chemistry in the Maryland College of Pharmacy. New (fifth) edition. In one octavo volume of 502 pages, with 44 engravings and 8 colored plates illustrating 64 of the most important chemie tests. Philadelphia: Lea Brothers & Co. 1895. Cloth, \$3.25.

The fifth edition of this well-known text-book has been prepared with great care, and the changes and additions made were necessitated by the desire of the author to bring the work into close relation with the new Pharmacopœia. The author has not altogether followed the orthography recommended by the Chemie Section of the American Association for the Advancement of Science because, as he states:

"Neither the leading chemical journals nor the U. S. Pharmacopœia have used the spelling." The first part of the work considers the fundamental properties of matter. The second treats of the theories of atomic constitution. The third and fourth, of the consideration of non-metallic and metallic elements and their compounds. The fifth is devoted to analytical chemistry and is also intended to serve the student as a guide to laboratory work. The sixth treats of organic chemistry. The seventh and last parts are devoted to physiologic chemistry. We note with pleasure that the decimal system has been strictly adhered to in all weights and measures, and that the degrees of temperature are expressed in the same system. There are eight colored plates showing the compounds of various metals, benzene derivatives, reactions of the alkaloids, the urine and test for its constituents. The colorings have been very accurately represented and add very greatly to the value of the work. We commend this book to our readers.

**Suggestive Therapeutics in Psychopathia Sexualis**; with Especial Reference to Contrary Sexual Instinct. By DR. A. VON SCHRENCK-NOTZING (Munich, Germany). Authorized translation from the German by CHARLES GILBERT CHADDOCK, M.D., Professor of Diseases of the Nervous System, Marion-Sims College of Medicine, St. Louis; member of the American Medico-Psychological Association; Attending Neurologist to the Rebekah Hospital, St. Louis, Mo., etc., etc. One volume, royal octavo, 325 pages. Extra cloth, \$2.50 net; sheep \$3.50 net. Sold only by subscription to the medical profession exclusively. Philadelphia: The F. A. Davis Co.

The translator says the favorable reception given Von Kraft-Ebing's "Psychopathia Sexualis" induced him to undertake an English version of the work by Dr. A. Von Schrenck-Notzing. The views for which the latter contends are able and are in striking contrast with those held by Kraft-Ebing, and for that reason deserve to be placed in English by the side of Psychopathia Sexualis. The author is a firm believer in the efficacy of suggestive therapeutics and hypnotic treatment in the cases of sexual pervers, paræsthesia and impotence. The author on page 302 gives a summary of results in thirty-two cases, which may be arranged as follows:

Failures . . . . .	5	=	15.625	percent.
Slightly improved . . . . .	4	=	12.5	" "
Essentially improved . . . . .	11	=	34.375	" "
Cured { with later report . . . . .	15	}	12 = 37.5	" "
{ without later report . . . . .	2			
Total . . . . .	32		100	" "

Of twenty-three patients, five were not amenable to hypnosis; eight passed into somnambulism, thirteen into hypotaxis, and three became only somnolent. In three cases the degree of susceptibility is not given by the authors. More than one-third of the cases were completely cured, and in ten of these it was possible to determine by later observation that the cure was persistent. In several cases the period of observation extended over a year; indeed Kraft-Ebing observed one case for two years, and I had the opportunity of watching a discharged patient two years and seven months. Four other patients were kept under observation more than a year, and a somewhat larger number longer than six months.

There is added to this book an appendix which was prepared for the English edition October, 1894, and which has been translated from this manuscript by Dr. Chaddock. In this appendix the facts are confirmed and the theories of the author seem to be well sustained.

The publisher deserves commendation for confining the sale of this book exclusively to the members of the medical profession.

**Transactions of the Royal Academy of Medicine in Ireland.** Edited by WM. THOMPSON, M.A., F.R.C.S., General Secretary. Dublin: Fannin & Company. 1894.

These transactions contain the usual arrangement of the

general rules of the Academy, list of officers, members, student associates, annual reports, and the like. It is then divided into six sections. Section of Medicine, which contains eleven papers. Section of Surgery, containing ten papers. Section of Obstetrics, eight papers. Section of Pathology, seven papers. Section of State Medicine, two papers, and Section of Anatomy and Physiology, seven papers. These last papers are followed by reports of collective investigations in the anatomic department of Trinity Medical College and in the anatomic department of Catholic University Medical School.

These collective investigations are anatomic, and the first is on the point of bifurcation of the abdominal aorta. The following results were given at Trinity College: 74.5 per cent. of the total number bifurcated at the fourth lumbar vertebra; the next place of frequency was on the intervertebral disc between the fourth and fifth lumbar vertebrae, the percentage being 19.2, while in 4.2 per cent the aorta bifurcated on the fifth lumbar vertebra, only 2.1 per cent. on the intervertebral disc, between the third and fourth lumbar vertebrae.

In males the taller the subject, the greater the tendency of bifurcation at the lower level; but in females the tendency, if any, is in the opposite direction.

At the Catholic University Medical School, out of twenty-two subjects examined, the aorta divided in fourteen on the body of the fourth lumbar vertebra, slightly to the left of the median line. Of the remaining eight, seven were opposite the intervertebral disc between the fourth and fifth lumbar vertebrae, and one between the third and fourth.

Another collective investigation was taken as to the level of termination of the spinal cord, and considered regardless of sex, the Trinity Medical School found that in 65 per cent. of all subjects, the cord terminated at some point on the first lumbar vertebra. In the separate examination of sexes, it was found that in males by far the greater number of cords ended on the first lumbar vertebra, while in females the cord has a distinct tendency to encroach on the second lumbar vertebra. In 52 per cent. of the female subjects the cord ended on the second lumbar vertebra, and in 48 per cent. on the first.

Mr. Roughlan, at the Catholic University Medical School, reports having examined nine subjects, in four of which the cord ended at the disc between the first and second lumbar vertebrae, in two at the junction of the middle and lower third of the first lumbar vertebra, in two at the junction of the middle and lower third of the second lumbar vertebra, and in one case at the lower end of the second lumbar vertebra.

Another investigation was made of the presence of the palmaris longus, plantaris and pyramidalis muscles, and the Trinity School found, in examining seventy-eight arms, the palmaris longus in 88.45 per cent. In 11.34 per cent. it was not represented. Considering right arms, it was present in 92 per cent.; absent in 7.9; whereas in left arms it was found in 86 per cent., and wanting in 15 per cent. from which, says the reporter, "it would seem to be more frequently absent on the left side." The plantaris was investigated in seventy-three legs, and found to be present in 93.15 per cent. No preference was shown for either side. In 7 per cent. there was scarcely any muscular belly. In one leg the tendo Achillis was three inches above the insertion. The pyramidalis abdominis was examined in forty-three subjects and found to be equally developed on the right and left sides. It was present in 60.47 per cent., and absent in 39.53 per cent. On the other hand, in females it was only present in 58.4 per cent., and absent in 41.5 per cent. The whole tendon shows the muscle is becoming extinct, this being more marked in the female sex.

It is curious to note the close correspondence of the examinations made in the Catholic University Medical School, which may be fairly said to be the "control" experiment. In thirty-four arms examined, the palmaris was present in 88.82 per cent. As will be seen above, this varies 42 per

cent. from the Trinity Medical School observations. In thirty-four legs examined, the plantaris was present in 97 per cent. The pyramidalis abdominis was present on both sides in 85.7 per cent.; present on one side in 7.2 per cent., and absent on both sides in 7.2 per cent. of the cases. Present on both sides in nine males. In five females it was absent once, and absent on one side once.

There are very many interesting papers in this volume, and the book will well repay careful study. The paper of Dr. Flynn, D.P.H., on "Recent Developments in the Study of Medicine" is worthy of careful perusal. It has especial reference to State inspection of industries and unhealthy areas, and in connection with notification of registration he quotes our Dr. Hewitt, of Minnesota, with approval.

**The Aseptic Treatment of Wounds.** By DR. C. SCHIMMELBUSCH, with a preface by PROFESSOR BERGMANN; translated from the second German edition by ALFRED THEODORE RAKE, M.B. Crown 8vo., pages 266. London: H.K. Lewis. 1894. Price \$1.25.

Dr. Schimmelbusch is the assistant of Dr. Von Bergmann at Berlin, and during the Tenth International Medical Congress many of our readers will remember the appliances for the sterilization of dressings which were there exhibited by Dr. Schimmelbusch under the direction of Professor Bergmann. There are sixteen chapters in the book, divided as follows: I, The Importance of the Aseptic Treatment of Wounds; II, Infection by the Air and by Contact; III, The Material Causes of Wound Infection; IV, Disinfection; V, Disinfection of the Surface of the Body; VI, Sterilization of Metal Instruments; VII, Aseptic Dressings; VIII, Aseptic Sutures and Ligatures; IX, Aseptic Drainage of Wounds; X, Aseptic Sponges; XI, Aseptic Use of Hypodermic and Aspirating Needles; XII, Aseptic Principles Applied to the Passage of Catheters and Bougies; XIII, Sterilization of Fluids for Washing and Irrigation; XIV, Operating in Sick Rooms; XV, Aseptic Operations and Wound Treatment; XVI, Improvisation of Aseptic Dressings for Emergencies and Treatment of Injuries. A rather extensive bibliography and a copious index conclude the volume.

With reference to the sterilization of catgut ligatures, the author says (page 119): "Von Bergmann has catgut treated with a 1 per cent. solution of perchlorid of mercury in 80 per cent. alcohol. The treatment lasts at least forty-eight hours and preferably longer. Catgut is placed in a mixture of sublimate and alcohol, which at first becomes cloudy and must be changed until it remains quite clear; it is afterward kept in ordinary alcohol. Experiments have lately been made with a view to making use of the high disinfectant powers of heat in the disinfection of catgut. For this purpose, steam and boiling water are quite out of the question, for in a few minutes under either, catgut swells up into a formless tangle and is converted into glue. The addition of strongly corrosive substances to the water, such as sublimate, chromic, or carbolic acid makes no difference as the author's experiments show. On the other hand, hot air can be used for sterilizing catgut. . . The catgut is heated for three hours up to 140 C. in a well-regulated, hot air sterilizer; in spite of the great heat the gut keeps its elasticity and firmness." The author thinks, however, that to obtain good results from hot air alone, it is necessary that a temperature of 140 C. should be reached very gradually, and it takes some hours. Moreover, the water must be extracted from the gut by previous immersion in alcohol. If the gut be placed in xylol, it can be brought to 140 much easier. The author gives numerous experiments and concludes by saying that, "in the Royal Clinic at Berlin, the old method of treating catgut with sublimate has been retained."

The details are as follows: 1, a glass receptacle is sterilized for three-quarters of an hour in steam; 2, the threads of catgut are wound upon glass reels or plates, as the case may be; 3, if the gut contains fat, the fat is removed by allowing it to lie in ether for twenty-four hours; 4, after the

ether has been poured off the gut is allowed to lie in an alcoholic solution of sublimate of the following composition:

Sublimate . . . . .	10
Absolute alcohol . . . . .	8
Distilled water . . . . .	200;

5, the solutions are renewed every twenty-four hours, and again every forty-eight hours. This part of the process must last not less than forty-eight hours; 6, the gut is removed from the sublimate solution and placed in alcohol, which should be absolute if but stiff gut is required, or diluted with not more than 20 per cent. of glycerin for a softer form of gut. Sublimate may be added as in the fourth stage of the process if desired; the vessels must be kept well closed. This method is easy to carry out even on a small scale."

This book is destined to meet with a warm reception in the United States, and we are sure that there is need for a handbook of this character at this time.

#### Periodicals.

**MEDICINE.**—A new medical journal will be started in Chicago within a few days. It will succeed the *Western Medical Reporter* which is to be suspended. The journal is to be a high class monthly entitled *Medicine*, under the editorial management of Dr. Harold N. Moyer, and a competent staff of assistants. Mr. George S. Davis, of Detroit, is the publisher. The new enterprise was launched on March 20 at an excellent dinner given by Dr. Moyer and Mr. Henry G. Furber to Mr. Davis. There were present the representatives of the medical press of Chicago, the members of the editorial staff of *Medicine* and the editor of this JOURNAL. All present wished the new venture success.

**ANNALES D'OCULISTIQUE.**—This interesting periodical founded by Florent Cunier, fifty-eight years ago, continued by Worlomont, and at present edited in Paris by Dr. E. Valude and Dr. D. E. Sulzer, (French edition) now has an American edition edited by Dr. George I. Stevens, which is an exact reproduction of the French edition published in Paris.

**THE PETERSON MAGAZINE.** New York: Penfield Publishing Co.—This magazine for March is one of the most profusely illustrated periodicals that finds its way to our sanctum. The physician's reception room table can have no more entertaining magazine than the *March Peterson*.

## NECROLOGY.

**MATTHEW DICKINSON FIELD, M.D.**, of New York city, died March 8, aged 42 years. He was a member of the famous family of Fields, hailing from western Massachusetts, he being nephew to both Cyrus W., and David Dudley, of that name; his own father was a civil engineer. He was educated in arts at Williams College, in medicine at Bellevue Hospital Medical College and then served as an interne. Three years after graduating, in 1882, he was appointed an expert in lunacy at the insane pavilion of that hospital, and in that capacity he had thousands of warped minds and suspects pass under his examination. He was early attached to the surgical staff of the Manhattan Elevated system, and later became the chief surgeon of the railway. He was a frequent expert witness in the courts, in cases where the for a time fashionable plea of insanity was in vogue for the liberation of criminals, as well as in the damage cases against corporations. He was married to Lucy Atwater about ten years ago, and she with two children survive him. He was a member of the Medico-Legal Society, of the Academy of Medicine, of the Society of Medical Jurisprudence, of the Alumni Society of the Bellevue Hospital Medical College, of the Neurological Society and of the County Medical Association. He was also a lecturer at the Bellevue Hospital Medical College. His final ill-health and demise were referable to renal disease, with cardiac complications, that had incapacitated him for professional work since last October. Interment took place at Stockbridge, Mass.

**G. W. SAMPSON, SR., M.D.**, pioneer of the Sandusky Valley, died at Tiffin, Ohio, at the age of 93 years. He practiced

for sixty years, and was president of the first medical convention in Ohio.

A. A. COLLIER, M.D., of Trenton, Mo., March 14, aged 65 years.—James T. Hester, M.D., of Athens, Ga., March 12, aged 53.—R. O. DuBois, M.D., of New York, March 9, aged 36.—John H. Ellis, M.D., of Chillicothe, Mo., March 10.—Mary Jane Lane, M.D., of Webberville, Mich., March 10.—Thomas Gann, M.D., a prominent physician of Jamestown, Ky., March 15.

## SOCIETY NEWS.

**Chicago Ophthalmological and Otological Society.**—The regular meeting was held at the Saratoga Hotel, Feb. 12, 1895, Dr. GRADLE in the chair. There were twenty-eight members in attendance.

The minutes of the last meeting were read and approved.

DR. WILLIAMS reported nine cases of cataract operated on from 1879 to 1888, in which a stitch was taken through the conjunctiva in order to close the corneal wound. These cases demonstrated that the eye is very tolerant of such sutures. In every case the results were good.

DR. BETTMAN said that Fuchs had tried them but had given them up. Their use is now being advocated in France in simple extraction, in order to prevent prolapse of iris and astigmatism, the stitches being put through the corneal tissue.

DR. COLEMAN had tried them and would always advocate them to prevent prolapse of vitreous.

DR. MEYER read an essay on "The Evidence for the Localization of the Visual Centers."

Society adjourned by limitation. C. P. PINCKARD, Secretary.

**The American Climatological Association** will hold its next meeting at Hot Springs, Va., June 13, 14 and 15, 1895. This time was chosen to accommodate members of the Laryngological Association, which meets in Rochester the beginning of the following week. Members desiring to read papers on this occasion will please send the titles as soon as possible to the President, Dr. S. E. Solly, Colorado Springs, or to the Secretary.

J. B. WALKER.

1617 Green Street, Philadelphia.

**The Ohio State Medical Society** will hold its fiftieth annual convention at Columbus, Ohio, May 15-17. It is intended to organize a special committee on medical legislation based upon county representation. The program is one of high scientific value, and a large attendance is expected. The officers are as follow: President, D. N. Kinsman; Secretary, Thos. Hubbard, Toledo; Treasurer, J. A. Duncan.

## MISCELLANY.

**A Theme for Mr. Ernest Hart.**—There were seventy-eight suicides in the city of Chicago during the first seventy-eight days of the present year. The JOURNAL is prepared for the inevitable "wishy-washy everlasting flood" of moralizing and predictions of rapid depopulation of what Mr. Ernest Hart is pleased to style "Porkopolis."

**Pean's Work in Abdominal Surgery.**—During the years 1889 and 1890, 2,200 patients were treated by Professor Pean in his service at the Hospital St. Louis, and more than a thousand were operated on. The number of deaths directly attributable to the operations was seven. From 1864 to January 1, 1892, M. Pean removed 2,100 tumors of the abdomen and pelvis. Of the 585 new operations performed, 47 alone were unsuccessful.

**Yellow Fever Martyrs.**—Dr. H. R. Stout, of Jacksonville, Fla., asks to correct a statement recently made in a New York journal, to the effect that a certain physician of the former

place was the only one who remained during the yellow fever epidemic of 1888. Dr. Stout says: "All the physicians of the city, with one exception, remained here, and not only that, but most of us had the disease, and four of our number laid down their lives serving their fellow men."

**The Profession in England.**—According to the Medical Directory for 1895 there are 26,790 physicians in the United Kingdom, of whom 21,055 are in England, 3,224 in Scotland and 2,511 in Ireland, or a mean of one doctor for 1,240, 1,280 and 1,875 of population respectively. If we add the members of the profession in the Army, Navy and Indian Medical Services we have a total of over 32,000. London has 5,742 practitioners, or one to every 830 inhabitants, while in Paris the number is only 2,237, one to every 1,100 inhabitants.

**Action of Iron on the Organism.**—Rosendahl (*Eira*) has often observed that subcutaneous injections of iron salts in frogs causes gastro-enteritis. The results of his experiments seem to show that the iron salts of the pharmacopoeia are not assimilated by the alimentary canal of man or mammals if this tube is in a normal condition. After their administration by the mouth they can not serve as material for the elaboration of hemoglobin, nor directly influence it. For the treatment of chlorosis homol, homogallol or ferratin are much superior to the preparations of iron in use at present. These new remedies may be destined to replace the latter, for the principal object of treatment of chlorosis is to increase the strength of the blood in hemoglobin.

**Liability of Railways for Surgeon's Malpractice.**—A comparatively new question which the courts are having to settle is that with regard to the extent to which a railway company that maintains a "medical department" is liable for the negligence of its physicians and surgeons. In a recent case where this question was raised, it did not appear that the company was under any obligation by contract to furnish surgical and hospital accommodations for its injured employees, and so far as was shown, its doing so was wholly voluntary. Nor were its employees under any obligation to avail themselves of the facilities for treatment offered, and paid nothing for them when accepted. That the company maintained its medical department for its own advantage and not for charitable purposes only, the Supreme Court of Iowa holds (*Eighmy v. Union Pacific R'y Co.*, decided Jan. 28, 1895, 61 N. W. Rep. 1056) might be presumed, but that did not alter what appeared to be the fact, that it was not maintained to discharge any statutory or contractual obligations. Its duty, under the circumstances, was to select a reasonably competent man for surgeon, and it was liable only for a neglect of that duty and not for any negligence or malpractice of the latter. And in performing such duty, it was bound only to the exercise of reasonable care and diligence.

**Some Things a Physician can Testify To.**—A physician was permitted in a personal injury case, to describe the condition in which he found the plaintiff, giving both subjective and objective symptoms at the time when the latter became his patient, a year and a half after the accident happened. This was objected to. But the Supreme Court of Wisconsin holds, (*Block v. Milwaukee St. R'y Co.*, decided Feb. 5, 1895, 61 N. W. Rep. 1101) that so far as his testimony related to the seriousness of the injury, this was competent. Nor was it liable to the objection that it was hearsay. So far as the knowledge of plaintiff's condition was derived from plaintiff's statements to him as a medical man for the purpose of receiving advice and treatment, the testimony was not incompetent for that reason. It was also stated as an error that the doctor was permitted to testify that plaintiff's condition, as he found it, could have been produced by contact with a wire heavily charged with electricity. And again the court holds that the testimony was both relevant and competent. The doctor was also permitted to give his opinion of the "reasonable probability" of the plaintiff's ultimate recovery from

his injuries. Of this the court says that while it was true that the whole testimony must establish, in the minds of the jury, more than a mere "reasonable probability," and must amount to proof to a "reasonable certainty," this ultimate fact was susceptible of proof by items of testimony which did not, separately, fully establish it. The phrase "reasonable probability" was equivocal. It was for the jury to give force to the doctor's testimony in accordance with the intention of the words used, rather than with a strict or technical definition of the words. This was not error.

**Prophylaxis of Ophthalmia Neonatorum.**—In a recent communication to the Obstetrical and Gynecological Society of Paris, Budin recommends the use of a solution of argentic nitrate, 1 to 150, for the prophylaxis of the ophthalmia of the new-born.—*L'Union Medicale*. He divides the disease into two categories from a clinical point of view—primary and secondary. The former occurs on the second or third day after birth; it is very grave if not attended to immediately. The secondary ophthalmia, occurring from the tenth to the twelfth day after birth, is less grave. Primary ophthalmia is most often due to the gonococcus or the bacillus of Weeks; secondary ophthalmia, to the streptococcus, staphylococcus or pneumococcus. Prophylactic measures are of two sorts: First, hygienic surroundings and exclusion of all contagious diseases—erysipelas, whitlow, conjunctivitis, etc.; second, the washing of the child's eyes as soon as possible after birth with an antiseptic. Crede's method—nitrate of silver, 1 to 50—is the best known. Other solutions used are sublimate—1 to 5,000, carbolic acid, 2 per cent., lemon juice, iodoform, etc. M. Budin, having noticed that Crede's solution often caused swelling of the eyelids and excessive lachrymation during the first few days, employed a solution diluted to one-third—1 to 150. Of 2,004 children treated thus, 2 had cases of primitive ophthalmia. The author recommends that midwives should be compelled to use this means, which entails little trouble.

**Medico-Literary Items.**—The author of the much quoted sketch "The Country Practitioner," has hitherto borne the pen-name of Ian MacLaren. His real name is Watson, the Rev. John MacLaren Watson. He is an eloquent preacher, a hard worker and a genuine Scotsman. He has published a volume of short stories under the title "Beside the Bonnie Brier Bush."

Ginn & Company, New York, will soon publish Daniel De Foe's *Journal of the Plague Year*, or as it is sometimes called, "The History of the Plague of London."

Dr. William H. Thomson will publish through the house of Harpers a religious work "The Parables and their Home: The Parable by the Lake."

Dr. Conan Doyle has been engaged to write a series of historical stories for the *London Strand*. He has chosen the title, "The Adventures of Brigadier Gerard," he being the modern presentment of a cavalry officer of the Old Guard of Napoleon. The last book issued by Dr. Doyle bears the title "Round the Red Lamp, being Facts and Fancies of Medical Life." These stories have not received the same favorable comment from the reviewers that was won by several of his earlier books. One critic says of the later stories that they are always morbid, pessimistic, and that when they happen to be optimistic, they are not exciting.

The number of new books on medical science and hygiene produced in 1894 was 140, new editions 21; this being a smaller number of new books than for 1893. Of this number, 161, there were 145 written by American authors. Fourteen were by English authors, imported in sheets and bound in the United States.

James R. Cooke, of Boston, an Eclectic medicine man, has published a book of nearly four hundred pages on "Hypnotism," claiming to have hypnotized 1,300 persons.

A recent book by Dr. S. Wier Mitchell, "When all the Woods are Green," tells the story of a party of pleasant folk who went salmon-fishing on one of the Canadian rivers.

Dr. Arabella Kenely of London, the author of a medical fiction called "Dr. Janet of Harley Street," has a new work, "Some Men are Such Gentlemen."

It is not generally known that the late Lieut. Frederick

Schwatka, U. S. A., was a medical man as well as explorer, author and lecturer. But such was the fact, he having graduated from Bellevue Hospital Medical College in 1876.

The Appletons have produced Quatrefage's second volume in his Anthropological Series, "The Pygmies." The translation is by Professor Frederick Starr. The author has here gathered all the latest facts regarding the small black races of Africa.

**The Bacteriologic Laboratory of the Harvard Medical School.**—(Prof. H. C. Ernst in *Harvard Graduates Magazine*, March, 1895.) Believed to be the first of its kind in this country in connection with undergraduate instruction, yet it is only nine years since the first lectures were given in it to medical students. Since then no year has passed without an enlargement, either of the laboratory or the scope of its instruction. Its primary function is to teach medical students. In the latter part of the first year there is a required course of lectures and laboratory work, and an examination follows. This course is brief, practical and covers rudiments needed for every practitioner. In the fourth year there is an elective course extending over half the year, and this is more extensive. A second function of the laboratory is the training of specialists giving advanced instruction, and encouraging original investigation. This function is fulfilled by a summer course of six weeks for practitioners and by two courses for graduates during the winter. The third function is the guidance of measures which affect the general public in connection with boards of health. The best example of this is the proved necessity for a bacteriologic diagnosis of diphtheria. The methods for this are simple but require special training and a well-equipped laboratory. The most promising and important research thus far carried on in the laboratory is that of the late Dr. S. C. Martin, whose death arrested his work at its most critical stage. It was an effort to isolate and cultivate the contagium vivum of cowpox with the intent of substituting this for the ordinary vaccine virus. This work was left at such a point that it seems as if money alone were needed for its accomplishment. Important original work is now being carried on by several investigators. It is probable that at least 12,000 examinations for diphtheria will be made during the present year. The Board of Health of Boston has appointed the head of this laboratory to take charge of the work of production of the antitoxin for diphtheria and to be responsible for the efficiency and accuracy of the work.

#### Society Notes.

**THE MEDICAL ASSOCIATION OF GEORGIA** meets in Savannah, Ga., on April 17, 18 and 19, 1895; officers elected are: President, W. F. Westmoreland, Atlanta, Ga.; Vice-Presidents, R. H. Taylor, Griffin, Ga.; W. Tate, Tate, Ga.; Treasurer, E. C. Goodrich, Augusta, Ga.; Secretary, D. H. Howell, Atlanta, Ga.

**THE ILLINOIS STATE MEDICAL SOCIETY.**—The annual meeting will be held the third Tuesday in May, 21 to 23. The annual dinner will be an interesting feature of the occasion. Although this is the forty-fifth meeting of the society, it is the first attempt to gather together the members at an annual feast. The well-known custom of the Massachusetts Medical Society is intended to be followed. Railroad rates have been applied for.

#### Hospital Notes.

At a meeting of the executive committee of the Johns Hopkins Hospital held in Baltimore, March 12, Dr. H. C. Parsons was appointed assistant resident physician, and Dr. Theobald Coleman, assistant resident surgeon.—The cornerstone of the Lamar Hospital at Augusta, Ga., was laid March 12.—The city council of Worcester, Mass., have voted to appropriate \$30,000 for the construction of a new ward at the City Hospital.—The Hygeia Sanitarium at Kalamazoo, Mich., was destroyed by fire March 14. Loss estimated at \$8,000.

### Louisville Notes.

**KENTUCKY SCHOOL OF MEDICINE.**—This institution has sustained a great loss in the death of the President of its Board of Trustees, Rev. John A. Broaddus, D.P., LL.D. Dr. Broaddus was a man of great worth, a prominent educator, a prolific writer, and a great scholar, and there is no man in the United States whose death could cause more widespread sorrow in Louisville than the death of Dr. Broaddus. He was born in Culpepper County, Virginia, Jan. 27, 1824, and died in this city March 16, 1895. As was chronicled in these columns recently, Dr. Broaddus made an address at the opening of the Kentucky School of Medicine and Hospital, and dedicated it to the cause of science, and for the use of the sick poor.

**DEATH REPORT.**—For the past week there were 86 deaths reported. Of these 23 were caused by pneumonia, 7 from bronchitis, 8 from consumption, organic disease of the heart 4, la grippe 2, cerebral meningitis 5, and there were 3 stillbirths. There were 53 males, 33 females; 57 white, 29 colored, 53 single, 33 married. Nine deaths occurred at the City Hospital.

**MATTHEWS.**—Dr. Jos. M. Mathews made the address before the Marion-Sims Medical College of St. Louis, Mo., on the 19th inst., at their regular commencement.

### St. Louis Notes.

**THE ST. LOUIS MEDICAL SOCIETY.**—At the meeting on March 16 the society discussed a resolution introduced by Dr. William Johnston at a previous meeting which urged the Legislature to pass the bill now pending for regulating the practice of medicine. The bill provides that no one shall enter into practice who has not previously obtained a certificate issued by a State Board of Examiners, to consist of seven members, four of whom are to be regular practitioners, three homeopaths and one eclectic. The society rejected the resolution, thus refusing to indorse the measure. Under the scientific program, perishable specimens were submitted by Dr. L. H. Laidley and by Dr. Carson; Drs. Frey and Pollak discussed the special features of the cases. A paper on Ainhum, with a specimen, was presented by Dr. A. H. Ohmann-Dumesnil, and Dr. H. H. Summa reported an operation, illustrated with a specimen. No reference was made to the proceedings of the Committee on Ethics in the Loftus-Marks case. It is understood, however, that all the evidence has been heard, and that the committee is ready to prepare its final report.

**THE BEAUMONT HOSPITAL MEDICAL COLLEGE** held its annual commencement exercises Thursday evening, March 14, at which seventeen graduates were granted the degree of M.D.

**THE BARNES MEDICAL COLLEGE** held its third annual commencement March 14, graduating a class of sixty-four.

**THE MISSOURI MEDICAL COLLEGE** graduated a class of seventy on March 19.

**THE MARION-SIMS COLLEGE OF MEDICINE** held its annual graduating exercises on March 18, conferring degrees on a class of fifty-four. Dr. J. M. Mathews, of Louisville, addressed the graduates of the Marion-Sims College on the evening of March 18.

**JUDGE RASSIEUR**, of the Probate Court, on March 16, denied an application for an inquiry into the mental condition of Arthur Duestrow, on the ground that this question was pending in a criminal court. The application was made at the instance of Dr. A. C. Bernays, who sought in this way to hasten the settlement of a bill for over \$15,000 for services rendered in attempting to save the life of the paranoiac's wife, for whose death Duestrow is now under indictment. The question of the prisoner's insanity is still undetermined in the courts.

**THE PRESENT MISSOURI LEGISLATURE** has passed the following bills relating to medical interests: Making it a felony to detain a person alleged to be insane without examination by reputable physicians; raising the age of consent to 18 years; to prohibit the practice or teaching of osteopathy without diploma; admitting oculists, aurists and dentists to the class of "practitioners of medicine," within the meaning of the statute exempting persons in these classes from jury service, fire department duty, etc; providing for examination of candidates for license as pharmacists by the State Board of Pharmacy.

The following bills have been defeated: Turning Fulton Asylum over to the homeopaths; exempting medical practitioners of all kinds from jury, fire department and military service; to compel labeling of packages of food and drugs with name of all ingredients—a pure food bill; making it a misdemeanor for a druggist to substitute some other article than that named in the physician's prescription without formal permission.

### Washington Notes.

**MEDICAL SOCIETY OF THE DISTRICT.**—At the meeting of the society held on the 13th inst., Dr. Fry reported a case of Caesarian section, both mother and child saved; and a case of symphysiotomy, child saved and mother made a prompt recovery without any alteration in natural gait. Both subjects brought out a full and interesting discussion. Dr. Glazebrook presented some interesting specimens which he had collected in the coroner's department, viz., stab wound of heart, severe wound of kidney from fractured rib, primary ulcer of stomach with perforation and fatal peritonitis, gunshot wound of spinal cord, endothelial sarcoma of vermiform appendix; and gave the histories of each. An interesting discussion followed.

**THE WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.**—The two hundred and twenty-fifth meeting of the society was held on the 15th inst. Dr. Adams read the paper of the evening, the report of a case of croupous pneumonia complicating scarlet fever. Dr. Sprigg reported a case of nephritis.

**THE BENEFIT FOR THE WOMAN'S CLINIC.**—The directors and friends of the Woman's Clinic gave a very pleasant musical entertainment for the benefit of the Clinic on the 11th inst. The friends of the hospital were out in full force and a good sum was realized. This hospital and dispensary is conducted almost entirely by women physicians and is doing excellent work.

**SMALLPOX IN THE DISTRICT.**—There were two new cases of smallpox discovered last week. Both were children in the same family. They were promptly removed to the hospital and are doing well.

**THE NEW SMALLPOX HOSPITAL.**—The work on the new smallpox hospital will very shortly be begun. The reduction in the appropriation from \$30,000 to \$18,000 will cause considerable delay and possibly some alteration from the original plans. The Commissioners are considering the advisability of, following the original plan as far as the appropriation will go, and asking Congress next year for sufficient funds to carry out the original designs.

**REPORT ON SEWERS IN THE DISTRICT.**—In compliance with a Senate resolution of February 22 last, the Commissioners have had prepared considerable interesting data relating to the paving of streets, the laying of sewer and water mains, etc., in the limits of Washington and Georgetown. A list of streets showing the number of linear feet of each, wholly or partially supplied with sewer facilities, has been prepared by Captain Beach. There are 102,300 feet of unsewered streets running east and west, and 72,250 feet partially sewered. Of streets running north and south, including Georgetown, there are unsewered 108,350 feet, and partially sewered 51,450 feet. In Georgetown there are 5,200 feet of unsewered

## ADDRESSES.

### AN ADDRESS

To the Graduating Class of the College of Physicians and Surgeons of Keokuk, Iowa, at the Opera House, March 5, 1895.

BY HON. W. W. DODGE,  
OF THE BURLINGTON, IOWA, BAR.

On an occasion such as this, are we not forcibly reminded of those beautiful words of Longfellow, in his "Psalm of Life:"

"Lives of great men all remind us  
We can make our lives sublime,  
And, departing, leave behind us  
Footprints on the sands of time;

"Footprints that perhaps another  
Sailing o'er life's solemn main,  
A forlorn and shipwrecked brother  
Seeing shall take heart again."

This evening with pleasurable interest we have witnessed the President of the College of Physicians and Surgeons present to the graduates of the class of 1895, their diplomas. One can scarcely appreciate the heart throbbings of a graduate who receives this "letter of recommendation," this "honor," this "distinction" from the faculty of the college that has been the scene of his hours, days and years of study and now like a fond parent witnesses the coronation of his successful labor. The graduate who worthily receives a diploma, which as its very meaning signifies, "is a letter of recommendation," should esteem the event as one of the proudest and happiest of his life.

To the graduate, the young doctor, may I suggest that you guard with jealous care this precious parchment. Frame it, hang it on your office wall, there to remain as a pleasant reminder of the labor and toil of your school days. Treasure it as an incentive to industry, ambition, and the use of your God given talents, so that in the autumn of your days, after you have witnessed the "leaves fall over the roots of the tree of life," your fellow graduates may not only proudly point to you as a credit to your alma mater, but the rising generation may find so much that is noble, sublime and grand in your "Footprints on the sands of time," as to emulate you as an exemplar.

When I received an invitation a short time since from the faculty of this college to address you this evening, I felt that I had been particularly honored, especially as I am not a member of the medical fraternity, but only an humble disciple of Blackstone. Therefore in the course of my remarks, confined to the time limit of thirty minutes, if I should inadvertently use the words "injunction," "mandamus," *et al*, referring to the medical method of the prevention of disease, instead of prophylactic or some pharmacopœia or materia medica term, I crave you give me the benefit of all "reasonable doubt" as to the honesty of my purpose.

From recent statistics I learn that there are in the United States about 725 medical colleges now in operation,

and that there are about 105,183 practicing physicians. In the State of Iowa it is said that we have some 3,618 physicians in active practice. There are seven medical colleges in Iowa; the oldest of these, if I am not in error, is the College of Physicians and Surgeons of Keokuk, and to-night we celebrate the fifty-fourth commencement exercises of this famous institution. It is the source of much gratification and pride, not only to the faculty of this college, but to the city of Keokuk, that the number in the class for this past year is 225, being an increase of nearly 100 per cent., and it is the largest class that has been here for twelve years. The past year shows an attendance of ladies twenty-one in number, two of whom have the honor of graduating in the class of 1895. The alumni of this college now numbers nearly three thousand. The high character of the members of the faculty of this college for learning and ability; the splendid and comprehensive course of study; a thorough equipment in all the essentials of its various departments; the past and present reputation for being one of the foremost and best colleges in the country, is what has given a name to the College of Physicians and Surgeons of this city to attract to it the magnificent attendance of this year, and to warrant a large increase in the years to come.

When one searches the labyrinths of the past for the fountain source of the science of the "healing art," he is led into the realms of tradition, the temples of the gods, and the wonderland of heathen mythology. The more one searches for the morning light, on the early struggles of this mystic art, the more he becomes impressed with the grandeur, the beauty, the beneficent purposes of the blessed science of medicine.

Away back in the dark ages of ignorance and superstition, it seems that the power of God lighted but few of the intellects of those days, and even those favored ones of Him who could heal those that touched but the hem of His garment were regarded by many as sorcerers, or possessed of the evil spirit.

To appreciate the curative methods of the modern physician, it is but for us to consider the means adopted by the ancient doctors of medicine in their mode of treatment of the afflicted. The priests who were the medicine men in those days, would establish themselves near thermal springs, or fountains, and among groves. Here would come the afflicted from every quarter seeking health. These places were nothing more or less than ancient health resorts, without the brass band and Wednesday evening ball of the present day health resorts. The healers of the sick would prescribe bleeding, purgatives, friction, and mineral waters. In many instances there would be recovery and benefit to health by reason of temperate habits, pure air and bathing. It seems that aversion with the ancient physician, as well as the modern,

I am sorry to say, played an important part. If the complaint was obstinate in yielding to the ordinary methods of treatment the fees would not only be increased, but the patient would be taken into a temple, there to be deluded into the belief that he must be purified by prayer, sacrifice and offering to the gods, before relief would come. The imagination of the patient played an important part, and if the ordinary treatment was slow in producing healthful results the priests would resort to the use of snakes and non-poisonous serpents that had been tamed for the occasion, and these horrible creatures were made to play an important part in the healing art, by causing dreams and impressions upon the minds of the deluded and ignorant patients.

As we turn the searchlight of investigation into the perspective of the remote ages of antiquity, seeking for truth and knowledge as to the early beginning of the science of medicine, we find helpful authority in the Bible, as also in heathen mythology. Do we not recall the words of Job, spoken to his tormentors: "Ye are forgers of lies; ye are all physicians of no value." And there is Jeremiah the prophet, lamenting over the condition of his people, and exclaiming: "Is there no balm in Gilead; is there no physician there? why, then, is not the health of the daughter of my people recovered?" We read in the Scriptures that Joseph commanded his servants and physicians to embalm him, this being about 1700 years B. C. Thus it is shown that the Egyptians possessed men who practiced the healing art and embalmed the dead, both of which must have required a crude idea of general anatomy.

It is to Greece, the land of art, that much of the ancient history of medicine can be traced, just as she furnishes every other art with the same historical advantages. Of the early physicians, Æsculapius is the most famous. By some he was considered the son of Apollo. A number of the cities of Greece contended for the honor of his birthplace as they did for that of Homer. Æsculapius, owing to his learning and wide knowledge of the science of medicine was given the title of the "God of Medicine." And there was Hippocrates, a great physician and philosopher, who was born in the year 460 B. C., and it is said lived a century. Because of his great learning and his wonderful discoveries in the field of medicine, and the fact that it is said that surgery was first practiced by him, he has been crowned the "Father of Medicine."

Galen was the most eminent physician during the second century, and the people had such great faith in his teachings that they were as a guiding star to the healers of the sick for a thousand years following. The creeds of Hippocrates and Galen were accepted by the medical profession down to the time of that bold "Prince of Empirics," Paracelsus, born in Switzerland in the year 1493. He was highly educated and made a Professor of the School of Medicine at Basel, and while occupying this place, with great solemnity burned the books of Galen, declaring at that time that he had discovered the "elixir vitæ," by which life might be prolonged indefinitely. He was nothing more or less than a charlatan, practiced the vilest arts, and being dissipated in his habits died at the age of 48 years.

Of more modern physicians, William Harvey will be recalled as the one, who, in 1616, demonstrated the circulation of the blood. There is John Hunter,

the famous anatomist; Edward Jenner, an English physician who made himself celebrated by the discovery of vaccination as a preventive for that dreadful disease, smallpox. This discovery was made by Jenner in 1776 while in the Alps watching the maids milking the cows. On the cows' udders were sores, likewise on the hands of the maids, and while the smallpox was raging in the neighborhood, the milkmaids were free of the disease. Jenner reasoned that the women had been inoculated with the "cowpox" which proved a prevention to the more terrible disease, smallpox. Pasteur, the great French scientist, gave to the world in recent years a preventive and cure for hydrophobia. Koch, the renowned German physician, discovered a "lymph" or tuberculin for the cure of tuberculosis. Americans point with pride to Dr. Samuel D. Gross, the "Nestor of American surgery." There is Dr. Behring, a German physician and student of Dr. Koch, who is credited with giving suffering humanity the "serum" or "antitoxin," as a prevention and cure for diphtheria. This discovery occurred but a few months since. Thus I could continue to name the illustrious descendants of Æsculapius who adorn the pages of ancient and modern medical history.

If, when Paracelsus proclaimed to the world his discovery of the "elixir vitæ," he had not in fact given to mankind a nostrous humbug, but a blessed boon, for indefinite continuity of good health and life, we should have but little use for the physician of to-day. It seems that the Almighty, in His inscrutable wisdom did not intend to confer upon a human being a power, divine in its character and effect. While such a blessing as an "elixir of life" has not come to us through human instrumentalities, let us not rail against the Divine will. While we consider the wonderful advancement in the sciences of medicine and surgery, the thousand and one discoveries for the amelioration of suffering humanity, it is as little as we can do to offer a thankful prayer to the Giver of All, for these rich blessings to mankind.

How true are the words of that Latin maxim: "*Mens sana in corpore sano*," "a sound mind in a sound body." While the stability and maintenance of government depends upon the intelligence and virtue of its people, it must not be forgotten that the health, strength and physical development of the coming generations must be as jealously guarded. In the early days the Romans were so ambitious to have only the finest specimens of manhood that the strictest laws were enacted relative to marriage; the weak and ill-formed were absolutely prohibited from entering into the marriage state, and only those possessing perfect health and strength were allowed to become the fathers and mothers of the warriors, statesmen and philosophers of those times.

In our day, while no such marital restrictions surround the people, all nations are taking advanced steps in the direction of prevention of disease, as far as possible. This is exemplified in the laws of quarantine at our seaports, the establishment of State boards of health, city sanitation, the power given to the health officer and local authorities to destroy buildings, fill up ponds or do such other acts as may be necessary to stamp out the hotbed of disease, and thus prevent the spread of a pestilence. It is by such heroic means that an epidemic, which if unchecked, would carry death and destruction throughout the land, is

prevented. It is to the intelligent physician, aided by the enforcement of sanitary laws, that the community is largely indebted for its good or poor health. It is to the physician that we must look in municipal bodies, to point out the sore spots that breed disease. Imperfect drainage, impure water, poor ventilation, densely populated tenement houses where squalor, dirt and filth exist, are as dangerous to the health and life of the people as a dog with the hydrophobia upon the streets of a city. Is it not true that physicians are the keepers of the public health and that by reason of their medical knowledge, their intelligence, and the knowledge that it is their duty to prevent, as well as to cure disease they can enthuse the people, give a cry of warning, erect bulwarks of defense, and determine the best methods to prevent an invasion of a dread disease? All honor, I say, to the educated, intelligent physician!

To speak of the "family doctor" is, as it were, to allude to a member of the family circle. He is near and dear to every one in the household. When dread disease or accident has suddenly stricken down a loved one, how anxiously we await his welcome footsteps, how, with trustful hearts, we listen to his cheering words, how he inspires us with the hope of a speedy recovery, how uncomplainingly do we follow his advice, and with hopeful smile we take the most detestable medicine he prescribes. His position in the family circle is one of sacred confidence. The secrets of a home are often imparted to him, while the happiness, love, and the all between man and wife are exposed to his honor or his treachery. He comes to the bedside of the suffering mother, when in her hour of untold agony and indescribable torture—when two lives are trembling in the hand of fate—to help with tender care in bringing into this bright and beautiful world of love, sunshine and happiness, a new life to gladden the home. It is from the cradle to the grave, at beck and call, the family physician comes to us in sunshine or storm, in daylight or darkness, like a ministering angel to soothe, comfort and cure. Do I not utter the sincerest of benedictions which come from the heart of mankind when I say, "God bless the dear, kind-hearted doctor?"

Members of the graduating class, I fully appreciate that I can add but little to the wholesome advice and timely suggestions of your instructors during your collegiate course of study; however, I beg the indulgence of a word. Remember, that the world owes no man a living, and that he who eats of the bread of idleness can not hope to succeed. That professional advancement and aggrandizement depends on individual effort. If you desire to reach the goal of fame and riches, remember that ambition, honor, and the use of your God-given powers will do more to aid you, than to pray to Hercules to strangle the serpent of competition. If you do not prosper, do not blame the rest of mankind. The Philosopher Hobbes, of Malmesbury, once said that, "the natural state of man is war." Your professional education has equipped you for the battle of life; from this night on it will be your duty to fight. Whether you will rise above the well-filled ranks of mediocrity depends on your own self, your willingness to continue the irksome search after knowledge, a persistent determination to surmount all obstacles, to keep your eyes toward the summit of professional eminence, where inscribed in living light are the immortal

names of the illustrious members of your profession, May heaven's choicest blessings be in store for you; may you live to enjoy a long, useful and happy life; may the hand of Fate bestow on you fame, wealth and happiness, and in the yielding stone of time may your fondest dream be carved.

### LECTURES ON INTRACRANIAL SURGERY.

#### II—CEREBRAL HEMORRHAGE AND ITS SURGICAL TREATMENT.

BY EMORY LANPHEAR, M.D., PH.D.

ST. LOUIS, MO.

By the expression "cerebral hemorrhage," is meant bleeding in the substance of the brain or into the cavity of the ventricles. Until very recently such cases have been regarded as beyond the pale of surgical interference. Indeed, only a few years ago Jacobson declared he could find but ten cases recorded as having been operated upon, and even Horsley—one of the boldest of cerebral operators—as late as July, 1890, advised tying the common carotid in every case of bad cerebral hemorrhage seen within four hours after the attack. But recently quite a number of operations have been reported with improvement in most cases, and surgeons are beginning to realize the brilliant possibilities of certain classes of hemorrhages, viz., cortical or surface hemorrhages, subcortical and ingravescant or progressive apoplexy.

Most authorities have, until lately, advised against operation for the reason (as expressed by Starr, of New York) that "when a hemorrhage has occurred within the cerebral hemisphere, lacerating the tracts and destroying the tissue, operative interference is out of the question, for tissue once destroyed in the brain is not repaired by Nature, and even if repair were possible the surgeon could not reach and remove the clot without further laceration of very important cerebral structures or serious cerebral hemorrhage." Experience has shown, however, that if the clot be removed early and be not too large, serious permanent injury may sometimes be averted; furthermore the brain may be freely incised in certain directions without marked harm, especially if over a clot which has already destroyed the communicating fibers; and the competent surgeon can usually control any bleeding he may cause in the brain or elsewhere.

Unfortunately it is not always an easy matter to make a differential diagnosis between a hemorrhage which may be safely reached by the surgeon's knife and one which is of basal or nuclear origin; nay, more—it is often a matter of some difficulty to find the bleeding point or even the blood clot after trephining. As a consequence the operator sometimes is compelled to adopt the advice of Krönlein:<sup>1</sup> "In cases where the surgeon is reasonably certain that the symptoms of compression are due to hemorrhage, exploratory trephining is to be continued until the hematoma is found." If not located and removed, at least relief from pressure is afforded by cutting a large opening in the skull, provided the bleeding has already ceased.

In the "ingravescant form"—that in which the symptoms are slight at the outset but gradually become more intensified—trephining should be done

before the blood reaches the ventricles; bleeding into the lateral ventricle may proceed from rupture of a vessel of the choroid plexus or the velum interpositum, but only in rare instances as the usual source is some artery in the brain substance, the blood simply breaking into the ventricles after a considerable clot has formed; so it is rarely necessary to open them, if operation be done early.

According to Edes, the most common form of intracranial hemorrhage has its seat in the white substance of the brain which is consequently more or less lacerated; such a clot may vary in size from a mere point to many ounces, filling a cavity nearly as large as the hemisphere. The vessel which most frequently bleeds is that which is given off from the middle cerebral and runs along the outer side of the nucleus lenticularis where it is covered by the external capsule, hence the large number of clots found in the white substance of the internal capsule. Therefore when the hemorrhage is not found as a meningeal or subcortical lesion as anticipated, this is the point to be sought if the symptoms indicate the middle fossa; if the clot be located outside the internal capsule it may be removed with comparative safety through a large opening in the skull—three or four inches by one and a half or two.

Hemorrhages in the thalamus opticus usually originate in the posterior communicating artery or the posterior cerebral and are too deep to be reached.

#### DIAGNOSIS.

No attempt at surgical diagnosis should be made while the patient is in deep coma. After the severer apoplectic symptoms have disappeared, embolism must be carefully excluded as trephining would be wholly inexcusable in the latter disease. The points of differential diagnosis can be found in all good text-books on neurology; they are foreign to our theme and are therefore not considered. It is well also, in determining the character of the disease to exclude hemiplegic forms of intracranial syphilis, and tumors which may be suddenly manifested; though since gummata, if accessible, should be removed as should curable forms of tumor, the differential diagnosis is not so important. The following rules will be found useful in deciding whether or not operation is justifiable when the diagnosis of cerebral hemorrhage is clearly established:

1. When there has been a blow upon the head, and hemiplegia, aphasia or hemianopsia follows, there is nearly always a hemorrhage which may be cured by opening the cranium at the point indicated by cerebral localization.

2. A slight premonitory attack, affecting speech temporarily or producing a heaviness of the hand or foot (or both) for a few minutes, if followed by hemiplegia may be taken as a good point in favor of operation, as the bleeding vessel is probably on the surface or very superficial.

3. When the case presents a history of moderate loss of power or even complete hemiplegia without loss of consciousness, followed in a few hours by the sudden appearance of coma, a marked fall of temperature succeeded by some fever—a hemorrhage has broken into the ventricles or just beneath the meninges, is still progressing and indicates immediate trephining; a day or two afterward will be too late—so if done at all it should be performed within a few hours, if possible.

4. Bilateral hemianopsia (blindness of correspond-

ing sides of both eyes) appearing suddenly is apt to be due to a hemorrhage in the occipital lobe of the opposite side, sufficiently large to be easily found, and justifies exploratory operation.

5. Vomiting, severe occipital headache and vertigo, with or without distinct paralysis, with ocular symptoms of nystagmus or strabismus, appearing suddenly, render a diagnosis of cerebellar hemorrhage probable and indicate exploratory trephining.

6. Paralysis of the third, fourth or sixth pairs of nerves indicates a lesion of the pons and contra-indicates operation.

7. Paralysis of very limited extent, especially if complete, are not often due to hemorrhage, being local palsies rather than the peripheral symptoms indicative of cerebral disease.

8. A very severe headache, followed by gradual but persistently deepening coma, with hemiplegia becoming more and more nearly complete, means a hemorrhage into the great basal ganglia—beyond surgical help.

9. Very sudden and complete hemiplegia and coma (coming on as if the patient were struck with a hammer) contra-indicate operation, particularly if the patient be under 50 years of age; the disease is probably embolism; heart lesions, endoarteritis, a septic process and syphilis strengthen the probability.

10. Profound coma and relaxation without hemiplegia usually depends upon injury of the pons and decide against operation.

11. According to Hughlings Jackson, convulsions, early rigidity and conjugate deviation of the eyes of a spastic form are conclusive evidences of superficial hemorrhage. But convulsions always accompany cerebral hemorrhage in young persons, regardless of location.

12. As an assistance in locating the clot, Durand-Fardel's figures may be quoted. Of 177 cases the hemorrhages were: in the ventricles sixty-six times; in the meninges thirty-one; in the corpus striatum and thalamus opticus twenty-two; in the white substance of the middle lobe eighteen; in the corpus striatum alone thirteen; in the corpus striatum and hemisphere twelve; in the anterior lobes eleven; in the posterior lobes eleven. From which we see that a considerable proportion may be regarded as within the reach of the surgeon.

#### OPERATION.

The surgical treatment of cerebral hemorrhage consists of: 1, ligation of the ruptured vessel; 2, pressure-stoppage of the bleeding if tying is impossible; or 3, arrest of the carotid stream by ligation—all for checking further bleeding; and removal of a mischief-producing clot after cessation of the hemorrhage, for many distressing symptoms may frequently be relieved by the operation.

Of the first: the probable location of the lesion having been decided, the head is shaved and cleaned by thorough scrubbing and washing with sulphuric ether or alcohol, and sublimate solution 1 to 1000, and a large flap of skin and pericranium laid back. A trephine is applied and the "button" removed, when the opening is enlarged to the size of two by three inches over the area involved. The dura is then incised and turned back and search made for superficial bleeding; if found, the clots are cleaned out and the vessel tied if still active, a small thread of catgut being passed around it by a curved needle and gently tied—it not being best to use much force lest

the fragile artery be cut in two. If not found upon exposing the brain an incision is made near the middle of the particular center indicated; this cut must be vertical to the ganglia, *i.e.*, parallel to the fibers of the corona radiata. The knife must be put more than an inch into the brain at the first stroke and the cut ought not to be more than an inch and a half long. The margins of this incision are gently pulled apart (with broad dissecting forceps or two flat blades) and the white substance inspected for the clot. When the clot is not found in the meninges or as a subcortical hemorrhage in the region indicated by cerebral localization, attention must be directed to the lenticulo-striate artery. This vessel (described by Gray as the largest of the antero-lateral ganglionic branches of the middle cerebral) is called by Charcot the "artery of cerebral hemorrhage" from the frequency of rupture. The point at which it most frequently gives way may be reached by cutting about one inch in the direction of the lateral ventricle just behind the lower end of the Rolandic fissure or in the temporo-sphenoidal convolutions at the upper margin. If not found here further exploration is scarcely advisable, though personally I should extend the cut first made so as to open the lateral ventricle, as in Case 4 presently to be related.

The clot being found, the cavity made by it is thoroughly cleaned out with the finger and irrigated with sterilized water at a temperature of 105 degrees. Any bleeding vessel must be caught (if possible) and tied with catgut as elsewhere in the body. When the cavity has been washed out a few strands of catgut are inserted through the cut in the brain, left long enough to protrude through the dura and scalp; or if the ventricles have been opened a very small drainage tube may be put in as advised by Keen. The dura is now closed by a continuous catgut suture—except at the point of drainage—and the scalp also in a similar manner. An abundance of iodoform gauze is placed around and over the opening, with much bichlorid gauze and cotton over all, properly held in place by bandages.

Of the second: when the bleeding point is found but for any reason can not be caught and tied, to check the flow one must first irrigate carefully and then pack the wound tightly enough to stop the hemorrhage. This method of treatment is not satisfactory because the gauze causes as much intracranial pressure as the clot and so the bad symptoms continue; but the packing need not remain more than thirty-six hours and may be very gently removed at the end of twenty-four hours if specially irritating. Improvement will be noted at once. (Even hemorrhage from the superior longitudinal or lateral sinuses may be controlled in the same manner, but the gauze must be left as long as forty-eight hours in such cases.)

Of the third: Victor Horsley first demonstrated, by experimental work on monkeys, that ligation of the common carotid upon the affected side checks the flow of blood in a ruptured lenticulo-striate artery as well as in the middle cerebral, the collateral circulation through the circle of Willis being at first very slight. The temporary cessation of the flow thus secured allows the bleeding to stop, and subsequent collateral circulation does not give rise to secondary hemorrhage. As ligation of the carotid can be done easily and as if careful antiseptic precautions be observed primary union may be obtained, the

operation is perhaps justifiable if performed inside of three or four hours, since by arrest of the carotid stream the clot may not become as large as might be the case if the vessel were left to bleed indefinitely; and so permanent hemiplegia, softening, etc., may be prevented in some cases. But it is not permissible to do this later than six or eight hours after the onset of coma.

#### CASES.

That the first rule laid down as favorable to operation is not without its exceptions is shown by the following case:

*Case 1.*—Thomas L., patient of Dr. J. E. Moses, of Rosedale, Kansas, received a blow upon the head which was followed by symptoms which pointed to hemorrhage in the lower Rolandic area and temporo-sphenoidal region of the left hemisphere, without evidence of fracture. I opened the skull low in the temporal region and removed a large clot from beneath the pia, which came from a rupture of the parieto-sphenoidal branch of the middle cerebral artery. The patient stood the operation well, all the symptoms of compression disappeared and we began to hope for speedy recovery. We were sure there was no possibility of contamination during the operation and the same care was observed at the first dressing when the drainage was removed. So we were greatly surprised when a meningitis arose soon after operation; which proved fatal six days after the injury. The autopsy showed a fracture of the base communicating with the middle ear—hence the meningitis and death.

Here is a case that doubtless might have been cured had there been no complicating fracture of the petrous portion of the temporal bone through which a meningitis from infection sprang. A peculiar feature was that there was not, from first to last, a single symptom—save the meningitis—which indicated fracture of the base.

A case illustrating the second rule was reported by myself some two years ago in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. The points of interest may be briefly summarized thus:

*Case 2.*—Dr. W. C. B., in June, 1891, consulted me about an attack of temporary aphasia and paresis of the right hand, arm, foot and leg; this passed away in a short time, leaving him entirely well but anxious. I diagnosticated a slight surface hemorrhage, and prescribed potassium iodid for possible tertiary trouble. Oct. 10, 1891, I was called to Carthage, Mo., by his physician Dr. R. T. Scott. He had had (about ten days before) a return of the aphasia and partial paralysis which passed away after a few minutes. He started for home some little time afterward but fell, totally unconscious and hemiplegic. In the interval between the "stroke" and my visit he never entirely regained consciousness; the hemiplegia was complete and though he could be aroused to a sufficient degree to understand simple things he could speak no word. During the few days immediately before my examination he had been failing very fast as indicated by rapid emaciation, paralysis of the bladder, dysphagia and fever (temp. 100 to 101 degrees F.) with terrible headache and insomnia; strength failing very rapidly. I therefore decided that the patient would die and that he should have the benefit of operation. I opened the skull over the motor and speech centers and found no pulsation of the dura which bulged into my large opening. Upon incising the dura the brain presented a discolored appearance and softening of the arm and speech centers seemed to have begun. The clot underlaid that portion of the cortex which presides over speech and motion of the face and extremities of the right side, and had exerted so much pressure upon other parts of the hemisphere as to render them blanched. The area of the clot is represented approximately in the accompanying diagram.

After removing the softening mass, including a part of the arm center, I irrigated with hot bichlorid solution, 1 to 6000, put in catgut drainage and closed the wound, replacing a part of the bony tissue removed. The duration of the operation was one hour and thirty-five minutes—some time having been lost on account of difficulty with the anesthetic. At one time we thought the patient would die upon the table, but he was put to bed in good shape. After closing

the scalp it was discovered that normal brain pulsation had returned at the opening in the skull. He slept nicely all night—quite a contrast to the moaning and tossing of two or three previous nights of insomnia for which sulfonyl and morphin (gr.  $\frac{1}{4}$ ) had given no relief. At 9 A.M. next day he appeared much brighter and nodded and smiled when asked if he felt better; the headache was gone; considerable motion in foot was obtainable upon requesting him to move. Improvement continued from that time on—the temperature being normal, and primary union being obtained. He sat up on the fifth day and on the twentieth day after operation rode more than two hundred miles. The subsequent history is one of restoration to health with ability to walk and care for himself; but the use of the hand has never been regained, nor has his speech.

From the fact that this patient seemed almost in *articulo mortis*, I am satisfied that the operation saved his life and probably had much to do in preventing permanent paralysis of the leg. Sometimes it is possible to give some relief even after a considerable time has elapsed, as is shown in a case almost precisely similar to the one just mentioned, the interesting features of which I will relate:

*Case 3.*—I. M., of Oklahoma, age 54, came under my care in June, 1892, affected by complete hemiplegia and aphasia due to a cerebral hemorrhage which occurred more than three months before. He complained of much headache upon the left side, insomnia, and general ill health; at times homicidal and suicidal tendencies had been noted following periods of sleeplessness and great irritability. I sent him to the hospital and with the assistance of Drs. T. B. Thrush and J. C. Maxson operated. I removed three one-inch buttons over the leg, arm and speech centers, and joined these openings with bone forceps, placing the fragments in hot bichlorid solution, 1 to 4000. On opening the dura no evidence of hemorrhage was to be seen except a white infiltrate over the speech and lower part of the arm centers. Believing there had been a rupture of the lenticulo-striate artery I cut through the brain to the region of the internal capsule. A large quantity of broken-down brain substance immediately oozed out; so I extended the incision upward and introduced my finger into the cavity, removing two fragments of the clot, each about an inch in length, together with a lot of *débris*. I then irrigated the cavity with sterilized normal salt solution, established drainage with several strands of catgut, stitched the dura and replaced the pieces of skull in a kind of mosaic, carefully suturing the scalp and applying a gauze compress so as to hold them in place; with the usual dressings.

Convalescence was speedy and uneventful. For three days there was a little fever (100 degrees F.) and no improvement was to be seen. But at the end of that time the temperature became normal, all the distressing head symptoms disappeared and then motion began to return slowly in the affected side. In a few weeks the patient was walking around by the aid of a cane with but little difficulty. Motor power has never returned in the hand, but the arm and forearm now have some motion. Speech was not restored. The bladder irritation and obstinate constipation—so prominent before the operation—entirely vanished, the mental symptoms never recurred and the patient regards himself as vastly improved.

The only case upon which I have operated which comes under my third rule was this:

*Case 4.*—J. P. E., male, age 52, a patient of Dr. Kistler, of Kansas City, I first saw at 4 P.M., on March 31, 1893. I found a hemiplegia of the left side which came on thirty-two hours before, while he was straining at stool; for some hours previously he had complained of vertigo, and had mentioned a "bad feeling" in the head and a heaviness of the left hand and foot two days before, at which time he went to bed with some vomiting—asccribed to biliousness, and for which a cathartic was administered; from this came the straining which caused the bleeding. He had a temperature of 100 degrees F. His mind was not much affected until more than twenty-four hours after the attack, but for eight hours there had been wild delirium and at the time of examination he suddenly became comatose. A severe convulsion would occasionally appear upon the paralyzed side, from which I expected to find a hemorrhage just beneath the membranes. I therefore ordered him to be carried to the German Hospital.

At 9 P.M., coma was complete, so without any anesthetic I opened the scalp and removed a piece of skull two inches by four inches over the motor area. The dura was very tense and pulseless and upon cutting the dura the brain protruded prominently into the opening; at which relief of pressure the patient began to show such signs of returning consciousness as to require a little chloroform. There were no surface indications of hemorrhage, so I cut inward through the parietal convolutions until the greatly distended ventricle was reached. Here there was a large quantity of semi-fluid blood, and broken-down brain tissue, which I removed as gently as possible and then irrigated with hot normal salt solution. As oozing into the ventricle continued persistently a little iodoform gauze was gently packed in the wound and the ventricle and allowed to protrude through the dura. Bulging of the brain was far less marked and after the dura was sutured around the gauze packing, cerebral pulsation was found to have returned. The usual dressings were applied.

At 10 A.M., April 1 the patient died—the attending physician said from "shock." Owing to my departure from the city no autopsy was held, so the source of hemorrhage was never determined.<sup>1</sup>

## ORIGINAL ARTICLES.

### SEVEN CASES OF CEREBRAL SURGERY.

BY C. E. RUTH, M.D.

PROFESSOR OF DESCRIPTIVE AND SURGICAL ANATOMY, KEOKUK MEDICAL COLLEGE; PROFESSOR OF CLINICAL SURGERY AT ST. JOSEPH'S HOSPITAL, KEOKUK, IOWA.

Believing that cerebral lesions not accompanied by fracture or even trauma represent a large proportion of the cerebral cases requiring relief at the hands of the surgeon, I present the following cases in support of that view:

*Case 1.*—May 9, 1891, was called to see L. G., age 5 years, who had four days previously sustained an injury by falling fifteen and one-half feet, striking her head on a plank sidewalk. No evidence of fracture of the skull was found at that time or subsequently. She slept eighteen hours in twenty-four, temperature 99.5, pulse 72. Sensation and muscular coördination normal. Appetite was good and bowels regular. Slight mental hebetude. Right side of head and face greatly swollen and discolored. Extravasation of blood under the ocular and palpebral conjunctiva. Left pupil responded to light readily. Swelling prevented inspection of the right pupil. A small swelling was found to the left and slightly behind the bregma.

Diagnosis, intracranial clot. Operation was made as soon as possible, the small swelling to the left of the bregma was cut down upon and a clot turned out

<sup>1</sup> I believe this man would have been saved if the operation had been made a few hours earlier, before the blood broke into the ventricles. That my patient died is no objection to the rule I have given, as a number of cases of progressive hemorrhage have been treated surgically by other operators with brilliant results.

which had formed between the bone and pericranium. Removal of a small disc from the center of this pericranial denudation brought another clot into view, which had formed over the anterior branch of the middle meningeal artery between the dura and anterior border of the parietal bone. Recovery was complete in two weeks without event.

*Case 2.*—C. B., age 71 years was struck Feb. 22, 1892, by the limb of a tree weighing eighty-five pounds which had fallen forty feet. The blow was received slightly to the right of the median line and in front of the fronto-parietal suture. The scalp wound indicated that the blow glanced slightly backward. I did not see the patient for several days after the injury, at which time the scalp wound had healed. Muscular incoördination marked and memory *nil*. Left patellar tendon reflex was abolished. Owing to dangerous cerebral compression symptoms, and noting no improvement in his mental condition on March 10, 1892, I trephined his right parietal bone beginning at the posterior part of the old scalp wound and extending backward three inches. On opening the dura a large amount of subarachnoid fluid was discharged. No clot was found. There was no laceration of cerebral tissue but arterial and especially venous engorgement was marked. Recovery took place without incident and was complete in three weeks. This patient was entirely relieved from former severe headaches which had occurred every two weeks for many years.

*Case 3.*—Jan. 18, 1893, I was requested to be present at an autopsy made by Dr. Kinnaman on J. T., aged 9 years, colored, who had died suddenly at his home under suspicious circumstances. Removal of the scalp showed contusion of its under surface, one and one-half inches in diameter, behind the fronto-parietal suture and to the left of the bregma. Removal of the skull cap showed an immense blood clot which extended from vertex to base and covered almost the entire left hemisphere of the cerebrum. The cause was evidently a blow on the vertex at the site of the scalp contusion and probably produced almost instant death. The skull in this case was very thin and possessed great elasticity. No fracture of the skull.

*Case 4.*—This case I place here out of order in point of time because it is traumatic in origin. Oct. 10, 1895, Peter V., aged 9 years was brought to me with a history of injury received in September, 1894, while in a wagon drawn by a badly frightened horse in a runaway. The nose was broken and driven backward and when I saw the case four months after injury, I found a scar crossing the nose at lower end of nasal bones, well out upon the left cheek, and about an inch to the left of the median line a small sinus discharged pus in considerable quantities. Pus was also being freely discharged from both the lachrymal sacs. The parents said that his nose though raised considerably at the primary dressing, was not its usual height. He was unconscious twenty-four hours after the injury, then appeared to recover completely save the discharge of pus previously mentioned which had been continuous since three weeks following the injury. Within four weeks he begun vomiting in the morning about 4 o'clock and then vomiting occurred at irregular intervals during the day up to the present. Parents noticed that for the past month he has not been as bright intellectually as normal, could not say some words he formerly spoke well, did

not see well, could not grasp anything firmly with the right hand and dragged the right foot. Would fall if he was not steadied when he attempted to walk. Pupils responded pretty well to light but a little sluggishly; convergence was impossible. Eye movements otherwise normal. Temperature normal, pulse 70. Diagnosed cerebral traumatism, with secondary degenerative changes in the left frontal lobe extending well backward near the middle line and towards Brocha's convolution. Trephined the left supra-orbital region. The pulsating dura bulged strongly into the opening. All the membranes were adherent from former inflammatory changes and the cerebral tissue greatly softened. With a cataract knife and small trocar I explored the major part of the anterior left frontal lobe, but found no fluid accumulation of any kind. Some broken-down cerebral tissue was removed, one-half inch opening was left in the dura and large gauze drain introduced. I could find no fracture of the horizontal plate of the frontal bone. Drainage was maintained for three weeks and at least calculation three drachms of broken-down cerebral tissue and old clot was discharged. Improvement in his mental condition was prompt, soon appeared normal, and he was able to speak any word that he had formerly known. He was able to walk without aid of any kind within one week after the operation. Great swelling occurred of the palpebral tissues with eversion of the conjunctiva. At the end of the second week tears were discharged at the old drainage points in the forehead but are now closed. Though the wound was dressed daily no suppuration has taken place.

It is too soon to make a positive declaration of the results in this case. The remnant of an old blood clot which seemed to be the basis of the bond of union between the membranes was almost certainly produced by the original injury, and forces one to the conclusion that early operation would almost surely have saved this boy much of the danger through which he has passed with better prospect of perfect recovery. In each of these cases there was no fracture, and the ages were from 5 to 71 years, yet in each there was a serious if not a fatal lesion. The only rational treatment must be that of removal of the products of trauma, whether that be blood clots, increased accumulations of cerebro-spinal fluid, abscess, or devitalized cerebral tissue. By early operation we may hope to give the damaged brain a chance of restoration by improvement in its circulatory possibilities before permanent impairment of function, paresis, paralysis, epilepsy, idiocy or death of the individual. In Case 3 death was probably instantaneous. In Cases 1 and 2 operated upon, one in four days, the other three weeks, recovery was perfect.

We have no hesitation in saying that all cases of cerebral trauma not accompanied by fracture in which symptoms of compression, dangerous, pronounced and persistent motor or mental disturbance

occur should be operated upon. No age is exempt from traumatic intracranial lesions without fracture, as is shown by my three cases in children and one in a man of 71, as well as a case reported to me by Dr. Gaston of a man 50 years of age who received a blow on the occiput which produced rupture of the middle meningeal artery under the anterior part of the parietal bone which was fatal from secondary inflammatory trouble about the clot. No fracture. The site of the application of the trauma or the course of the branches of the middle meningeal artery will indicate the points to be explored in the absence of localization symptoms. We can see the necessity for a guarded prognosis and can not pronounce our patients positively well till the lapse of many weeks or months, and should keep them under observation so as to detect the first evidence of danger.

*Case 5.*—E. B., age 36. Epileptic since 14 years of age. Memory and general intelligence greatly impaired. Nystagmus pronounced. General health good. Paretic on left side from infancy, with very little use of the left hand and drags the left foot. Convulsions started in the left side to which they were confined until they became general ten years ago. No history of injury or marked assymetry of the skull. Jan. 14, 1894, I removed three inches of bone over the fissure of Rolando, and identified the arm and leg centers with brain electrode. Convulsions were defective in development, pale, and widely separated by broad and shallow sulci. Recovery was prompt and apparently complete in two weeks and the relatives thought they noted marked mental improvement but that is to be taken with considerable allowance. He contracted double pneumonia from which he died at the end of one month from the operation. This case was operated upon in the hope that it might lessen the frequency and mitigate the severity of his epileptic attacks and thus, if possible, save what intellect he had.

*Case 6.*—W. W., age 38. Steamboat raftsman. Well and exceptionally strong till Oct. 18, 1893, at which time he became suddenly and completely paralyzed in the left arm and leg. He was infected with syphilis eighteen months previously. April 14, 1894, six months after the onset of the paralysis, I diagnosed the cause of the paralysis to be embolic obstruction of the ascending parietal and frontal arteries to the motor area of the right side, and removed three and one-half square inches of bone along the fissure of Rolando. Brain was anemic, pulseless, did not bulge into the opening, and no muscular response could be obtained by the electrodes beyond a general tremor. No abnormal resistance could be detected. Recovery was complete from the operation in three weeks and at the end of six weeks he was able to walk by the aid of a chair, but the gain that was at first promised in the arm was not maintained. His skull was scant one-half inch thick and composed almost entirely of dense compact tissue. He left the city at the end of seven weeks but returned in October, 1894. Nov. 17, 1894, I did a secondary operation on him before the Eastern Iowa District Medical Society, in which I nearly doubled the space from which the bone was removed, being mainly extensions backward from the upper, and forward from the lower end of the Rolandic fissure. Improvement following the secondary operation has not been as marked as that following the first one, and is probably due largely to the lapse of time since the primary lesion and

teaches us another lesson in promptness. He can now walk by the aid of a cane.

This case would seem to indicate that reduction of the cerebral tension to below normal by removal of bone and establishment of drainage, may bring about considerable restoration of function in portions of brain supposed to be damaged beyond the possibility of repair, from embolic obstruction of a terminal artery. At the secondary operation in this case, I learned that the edges of the old opening were beautifully beveled, equally from the outer and inner tables, and that the pericranium and dura were blended to the opposite side, so that the actual gain in cerebral space is represented by one-half the thickness of the bone, less the normal convexity of the part, for the membrane will pass directly across from the bony attachment at one side to that of the other, if it is not carried outward by intracranial pressure. From this, it will be seen that the gain in cerebral space, by removal of the skull, will be relatively greater with a small opening. In this case it was nearly one-fourth inch, for the thickness of the skull was scant one-half inch. This relief of tension may also enable neighboring parts of the brain to take up part of the work of a destroyed or crippled center, as is the case where a center is excised.

*Case 7.*—Nellie P., age 5 years. Was well until after a fall at the age of 1 year, at which time she could walk and talk some. Following this fall she had nine convulsions in three weeks. Three weeks later she had spasmodic contractions of the entire left side for twelve hours, followed by complete paralysis of the left arm and leg. Twenty days later she had an intense fever accompanied by general convulsions for eight hours, closing with movements only of the left side. She has never spoken since the attack and could not walk again until one year ago. Drags the left leg and does not use the left arm. Now has frequent general epileptic seizures and is idiotic. May 23 did right-sided craniectomy and removed three inches of bone over the fissure of Rolando. Found defective development of the cerebral convolutions. There was no assymetry of the skull and no evidence of fracture. Though I am convinced that this patient sustained a cerebral injury from the early fall, which prompt and intelligent surgery might have readily recognized and removed, the time for such procedures had gone by. She took the anesthetic badly and died in eight hours.

Early signs of collapse in this case prevented application of electrical tests for the motor centers, and the ultimate result has not lessened my skepticism regarding the justifiability of craniectomy operations in cases of idiocy, even if due to traumatism when there is no assymetry of the skull, and the history of injury dates back to early life and has been of several years' standing. In the adult we can hardly expect marked improvement in motor disturbances after the lapse of one year with or without operation. In Case 6, paralysis of the arm occurred twelve hours before that of the leg, and would indicate that the ascending frontal and parietal arteries arise by a common trunk from the middle cerebral; the ascending frontal was first plugged and the embolism, probably specific in origin, developed backward so as to involve the ascending parietal in twelve hours and thus produce complete paralysis of the motor area of the opposite side.

## WHEN SHOULD CONGENITAL CLEFT PALATE RECEIVE SURGICAL TREATMENT?

Read before the Chicago Dental Society.

BY C. S. CASE, M.D., D.D.S.

CHICAGO.

This is a subject upon which there is a decided difference of opinion among eminent specialists who pursue distinct methods of treatment. I believe this to be mainly due to the fact that in the two general classes of treatment for congenital cleft palate, that which relies upon artificial means for its success is performed by the dental profession, while the other, or surgical operation, is confined almost entirely to the medical profession. And as in other instances, when these two professions are called upon to treat the same character of disease or deformity, there has never been in either profession an intimate knowledge of the method of treatment peculiar to the other, or an appreciation of its inestimable advantages in certain conditions. Were the relations of the two professions of a more intimate nature, these things might become so adjusted ethically as to render interference at times by one or the other inexcusable and, possibly, subject to the law of malpractice.

Dr. Norman Kingsley, of the dental profession, who has doubtless had the largest experience in the treatment of congenital cleft palate by the artificial method, has published the following radical opinions in reference to treatment in this deformity: "The only cases in which surgical interference is justified are those rare ones of slight separation and with an abundance of tissue where the division of the muscles would not be essential to success. Of the hundreds of cases that might seek surgical aid, very few would come under this exception; and although the practice has been tested in a thousand cases by the most eminent surgeons of their time, it has resulted in such a uniformity of failure, considered as a beneficent operation, that it should have been utterly abandoned long ago."

Although this never could have been written with a full knowledge of the success of surgery when employed during babyhood, or at a time, I claim, when surgical interference should be considered as imperative as the operation for lacerated perineum and other conditions which are discovered and demand surgical treatment as early as advisable after birth; yet most unfortunately it is true, that almost every professor of surgery in medical colleges, who has had more or less experience in operating for congenital cleft palate, will perform this operation before his class upon every patient who presents for treatment, of whatever age or condition of cleft, or tissues.

I can understand how there may be an occasional case of cleft palate with sufficient redundancy of tissue to warrant a skillful surgeon in attempting an operation for a patient after the age of 5, 10, or even 15 years, and with every probability of obtaining a natural palate that will meet all the requirements of speech. But successes of this kind are so very rare they prove nothing, neither do they justify the wholesale attempts that are made where there is no possibility of doing more than to surgically unite the borders of the cleft. And far too often, as Dr. Kingsley says: "When the only apparent object was to gain *éclat* by the skillful use of the knife in a difficult case before an admiring audience, and with

no possible hope of even a union or surgical success."

Surgical success in these operations consists apparently in a permanent closure of the fissure by uniting the tissue along the border of the cleft. But this is not success, unless the only real object that is worthy of consideration under the circumstances can be attained, *i.e.*, a palate which in conjunction with the pharyngeal muscles will enable the patient among other things to completely close the naso-pharyngeal passage. This is absolutely necessary for perfect speech; not only to obtain the proper quality of tone, but to enable them at times to forcibly expel all the air, which is the vehicle of voice, through the mouth, and often through a narrowed opening with intensified force,—as in speaking the words hiss, hush, etc. And again, in those vocal interruptions which can only be perfectly produced by a complete closure of every avenue of escape of an accumulated pressure of air, with the production of a sudden vocal explosion at the lips, or between the tongue and different locations along the roof of the mouth or palate, as in pronouncing the letters B, T, K, etc.

I have been told recently by an eminent surgeon that even after a staphyloplastic operation, the velum palati could be surgically extended to any desired length. This is a claim which I believe is not justified by anything which has yet been accomplished. If so, a practical proof would be hailed with joy and go further towards establishing this very doubtful claim than the bare assertion of any man however eminent.

It has been my intention for some time to bring the subject of this paper prominently before the surgical profession for general discussion, with the hope that it might lead to a careful comparison of the advantages of artificial vela and obturators, with the surgical operation known as staphyloplasty in congenital cleft palate.

In presenting this paper to the Chicago Dental Society, I feel very much like apologizing for occupying your valuable time with a subject relative to which so few dentists are actively interested; and yet it has seemed to me eminently proper that a question relative to an operation which in all its branches belongs distinctively to dental and oral surgery should emanate from a dental society, whatever larger influence I may hope for it in other quarters where only one branch of the operation is so unhesitatingly practiced under all conditions, and where little is really known of the other from a practical standpoint.

I shall not go into the causes and differential conditions of cleft palate, or attempt a detailed description of any particular method of treatment; but will endeavor to treat the subject from a popular standpoint, taking it for granted that my hearers of the dental profession are sufficiently well informed in every branch of this subject for the purposes of this paper.

What is the principal object of the patient, or friends of the patient, in submitting to an operation of this kind? It is almost invariably for the purpose only of perfecting or benefiting articulate speech, which is often so impaired in tone and vocal articulation as to destroy every hope and possibility of a life that otherwise would be an ornament to society and successful in every undertaking.

At the close of last year's term of school, I received a letter from a young man who had come to me two

years before with speech so imperfect as to be understood with the greatest difficulty, and for whom at that time I inserted an artificial palate. Accompanying the letter was a program of the graduating exercises of the High School of Manistee, Michigan, in which he was down for the "Salutatory," having been given the highest honor of his class not only, but a position which could not be properly filled by a person with indistinct or imperfect utterance of the English language. The following is a part of his letter: "I have sent you under separate cover an announcement of the graduating exercises of the class of '94, of which I am a member, thinking you would like to see the part you have played in the exercises. For I owe it to you that I am to take part." He has since written me from the University of Michigan, where he is taking the classical course with high anticipations of the future because, as he says, his friends now tell him that he speaks with perfect articulation.

This is only one of many similar instances in my practice and the practice of other specialists, showing the perfect success of artificial palates that have been inserted after the age of 15.

For the purpose of bringing before you unquestionable evidence of the value of the artificial method of treatment in congenital cleft palate, I have selected from my *clientele* two patients who are with us this evening, whose experience as regards time in wearing an artificial palate is widely different. The one gentleman, now 30 years of age, began about 15 years ago, while the other, a young man 19 years of age, will be remembered as coming before this society a year and a half ago, two weeks after the insertion of his first artificial palate. At that time he was presented by me merely to show the improvement principally in the quality of his tone, and in certain enunciations that were previously impossible. When you hear these gentlemen speak, as they have kindly consented to, after the reading of my paper, you will be convinced, I think, that were you to meet either one in private conversation—where the opportunity of using a lower tone than is possible in this hall would be greatly to their advantage—that nothing in the character of their speech would suggest the deformity under which they labor.

The treatment for congenital cleft palate of whatever character, is usually the crowning event of a patient's whole life; for upon its success in enabling him to speak distinctly depends his future. It is often the one event for which they have been saving and looking forward to for years; and what is of a far more serious nature in throwing the responsibility of a being's future upon the operator who attempts the correction, it is usually the only operation they will undergo, whatever its final result. By this I do not mean they will not allow the operator to perfect or improve his first operation; but that after they have first investigated the subject of treatment, choosing the method which seems to promise the greatest benefit, and the operator upon whose skill so much depends, they usually will forever abide by the consequences. In some instances their means will not permit a second outlay of money, to say nothing of other things, for a second or different operation, the success of which they have much reason to doubt. In other instances, if the operation is a surgical one, which is successful only as to the perfect union of the fissure without material improvement in speech, or

with an improvement which is not equal to that which certainly could have been obtained by a skillfully adjusted artificial palate, the latter operation is rendered impossible, unless the cleft is disunited for the proper insertion of the artificial velum, an undertaking that will rarely be submitted to, even if it were possible for results equal to those which might have been obtained in this way at first.

Of the hundreds that are yearly added in private and hospital practice to the list of patients having a partial or complete disunion of a once surgically united cleft palate, few ever apply for a second operation of any kind for various reasons. It is doubtful if many of these patients could acquire the ability to successfully use an artificial palate with the muscles of the natural velum and uvula stiffened and contracted by the cicatricial tissue of the operation, when so much depends upon the mobility and sensitive activity of the natural muscles in acquiring the power to properly use an artificial velum as an adjunct of speech; just the same as the muscles of the hand acquire the ability to use an instrument of any kind in the accomplishment of an object which could not be attained without that particular instrument skillfully fashioned for the purpose and made to do the bidding of muscle and brain in the production of beautiful music or the restoration of a decayed tooth. If the muscles have lost the possibilities of their natural cunning, either by disease or by a surgical operation, the most perfect brain and instrument are powerless to accomplish more than indifferent success.

When patients have come to me from time to time with a surgically united cleft, realizing the inadequacy of their operation and with the hope of improvement by artificial means, it has been my custom to tell them that nothing could be done without first opening the suture, at least through the soft palate, and then with no promise of success beyond the probability of an improvement in their speech.

I have one patient who is at present the Auditor of the Toledo & Ann Arbor R'y, who underwent surgical treatment for congenital cleft palate when quite a boy at the hands of those eminent surgeons, Drs. Agnew and Garretson. I found the soft palate perfectly united, but anterior to this in the hard palate there was an ovoid fissure about the width of a cent. This was covered by a plate with a flexible extension made by Dr. Patterson, of Kansas City. When I first met this patient, about six years ago at Jackson, Mich., he was very skeptical as to the benefits of any mode of treatment. He was accompanied by his sister who had brought her daughter, who was suffering from the same deformity, for consultation, or rather for investigation of my method of treatment. When I heard his strongly expressed doubts as to my ability to render a service that would enable his niece to speak perfectly, I privately sent for one of my cleft palate patients, whom I introduced to them with no explanation. After quite an animated conversation, in which my patient did most of the talking, I told them that the young man was wearing one of my palates. At this they were greatly surprised and could hardly believe it until they had examined the palate and saw the cleft which was very large and apparently quite difficult to treat. It is needless to say that this decided the operation for his niece, which proved so successful that later—about three years ago—he insisted upon my making the attempt

to construct an artificial palate for him without opening the suture in his soft palate. I found upon trial with a certain form of flexible rubber palate that the requisite posterior extension or veil of the palate could be rolled up and thus thrust through the fissure, where it was firmly buttoned in place by a lingual extension of the rubber. When in place, the artificial velum now unrolls to the proper width and extends fully three-fourths of an inch beyond the posterior border of the surgically united palate, without even then coming in contact with the posterior pharyngeal wall, until raised by the muscles in the act of closing the passage to the nose, on the principle of a valve, the same as all artificial vela are successfully worked. This instrument he has used quite successfully, and, as he writes, "with marked improvement in his speech; especially in using the telephone which had previously given him much trouble."

We have with us this evening a gentleman about 30 years of age, who was also operated upon surgically when a boy with the usual result to speech, so far as I can learn, of all operations performed after 5 or 10 years of age. When he came to me about six months ago I found the fissure perfectly closed, but with the velum palati so rigid and short that it could not be made to reach within a half inch of the posterior pharyngeal wall, in consequence of which his speech was quite imperfect, especially in quality of tone and in those vocal enunciations which require a complete closure of the naso-pharyngeal passage. After weeks of consideration, he finally consented to have the suture opened through the soft palate for the introduction of an artificial velum, which you will find has brought about an improvement in his speech that is not often possible in so short a time under the most favorable circumstances for patients at his age.

The next patient I wish to present to this society is a woman upon whom as perfect a staphyloplastic operation has been performed as is possible. You will find upon careful examination of this case that the operator has taken advantage of the most approved and modern method of cutting those tense palatal muscles on either side which have so often been the cause of ultimate disunion of the suture on the one hand, and, on the other, when union has been permanent, in a tenseness, immobility and shortening of the velum that aborted its every possibility of becoming a useful adjunct of speech. I do not wish to be understood as exhibiting this patient—who now speaks so imperfectly as to be understood with the greatest difficulty—as a fair sample of the invariable result in speech arising from a staphyloplastic operation, for I have met with a number whose vocal articulation was far more perfect. On the same principle also, this is true of many with open clefts who have received no treatment whatever. My main object in presenting this case is to show a condition which may follow the most skillful and successful operation—considered from a surgical standpoint—performed during adult life with every advantage of an abundance of palatal tissue, and one which I have good reason to believe is a fair sample of the relative improvement to speech in a large proportion of all staphyloplastic operations that have been performed later than infancy, or very early childhood. I also present this case as an illustration of what many skillful surgeons are willing to attempt for patients

even older than 40, with no probability of success considered as a beneficent operation, and with nothing in fact but the bare possibility of surgically closing a fissure that has never given them trouble beyond the disadvantage of imperfect speech, which their operation can not remedy. It is a sad commentary upon surgery when its most skillful operators are willing to subject some poor human being to an operation that causes great suffering, with loss of time and money; and worse than all, places him beyond the pale of possibilities that might result from other hands.

Unfortunately, these instances are not confined alone to the medical profession, but have arisen from the ambition or cupidity of skillful dental oral surgeons whose education should give them a perfect knowledge of the advantages of the artificial method. Why would it not be far more commendable for these gentlemen to allow, and even advise, such patients to first try the artificial method, and then if that fails, the surgical operation could be performed as well—a thing which can not be said of the artificial method if the operations are reversed as to time.

To recapitulate the claims of my paper, the first point I have attempted to make and conclusively prove is that the artificial method of treating congenital cleft palate for patients under 15 or 18 years of age can be relied upon when skillfully performed, as furnishing a sure means by which may be attained perfect vocal articulation, free from the undesirable nasal tone which is characteristic of this deformity. And while the same success can not always be promised at a more advanced age, a decided improvement in speech has invariably resulted in all cases where I have been allowed an opportunity to properly develop the artificial palate according to the needs and possibilities of the muscles; and, on their part, there has been a proper persistency in training the voice to speak distinctly. There are many instances where patients have begun wearing artificial palates as late as 30 years of age whose speech in ordinary conversation would not produce a suspicion of their deformity, as instanced by one of the patients whom I shall present at this meeting.

2. With the surgical method of treating cleft palate, when performed later than infancy or very early childhood nothing like the above results have been attained, with perhaps an exception in a few isolated cases. Certainly nothing to warrant the most skillful surgeon in operating, as they commonly do, for patients older than 20, or even 10, where the cleft extends partly through the hard palate, and with the tissues of the soft palate comparatively scant from non-use during the age of its growth and development.

3. When should congenital cleft palate receive surgical treatment? I answer most emphatically, as soon after birth as safety to life will warrant. But after 5 years of age and even earlier, be the cleft great or small, the operation should be performed only in those rare instances which promise an unquestionable assurance of resulting in the desired length and mobility of the united velum palati.

The following is taken from the approved minutes of the January meeting of the Chicago Dental Society at which the above paper was presented:

"The several patients to whom Dr. Case made reference in his paper were presented to the society, and through the medium of short extemporaneous speeches demonstrated the fact that in every instance

their power of speech was fully in accord with his claims.

"One young man gave a remarkable exhibition of his ability to whistle, which was a surprise to all who knew the impossibility of performing this function with a cleft of the palate, unaided by surgical or artificial means."

A. H. PECK, Secretary Chicago Dental Society.

## SLEEP THE RESULT OF DIFFERENTIATION.

BY GUIDO BELL, M.D.

INDIANAPOLIS, IND.

### SYLLABUS.

There are no atypical cells in the organisms; for this reason and others there must be something guiding all biologic processes—species in action is identical with vitality.

The fundamental functions are assimilation and proliferation; differentiation is the tendency of bringing assimilation and proliferation in contact with the outer world under most favorable conditions.

These influences are either food and air or disengaged (cosmic) energy. Food is preeminently chemic change and is carried on a neutral road through the body; cosmic influences are carried in an electrical form also on neutral roads. Blood and nerves are neutral in consequence of their metaplastic nature as hair and nails are.

All biologic phenomena are subject to the law of conservation of energy but controlled by species.

Trypsinogen and inogen are transformed by a specific irritation into trypsin, or mechanical force, respectively. Similar to this, we have to assume a product in the cerebral cell which, on irritation, becomes an "imprint" consuming oxygen. The nerve cell puts itself asleep.

It is proper and correct that "experimental science ought to vigorously forbid itself all research relative to first causes." But excluding such a research as not pertaining to experimental science we have taken our aim too short in physiology.

Within the last fifty years, since medical sciences have been conceived from the standpoint of induction and taught so in regular schools, it became evident that medical practice did not make equal progress as science did, and that American medical practitioners with less schooling can well compete with their European colleagues.

The cause of this seems to rest in the fact that the young practitioner can not translate easily the language of science into that of practical life. It is difficult for him to get the essentials of a phenomenon by abstraction and to compare them with his doctrine. He learns using terms without a clear conception; he speaks of constitution, temperament, vitality and so on and refers to them in his judgment and action.

It seems to be just and commendable to draw forth these terms from indistinctness, and to lay down the "known" and the "knowable" but not yet known.

My endeavor is to plead in this article on sleep for the term, vitality. I choose an object to be concise and clear, and I select sleep because she, a natural healer, offers the best opportunity of viewing nature's workshop.

I define vitality as the metaphysical principle active in the development of the individual and in procreation. Both changes and disorders, inherited and acquired in life, must be included in a given case. Vitality is identical with species or type. I will try to show that the law of conservation of energy can not be understood in biology if not placed under the control of species. Only such forms of energy are disengaged in the cell, and so much of each as are in accord with its design.

Sleep is a normal condition of the human body; it is periodical rest with a higher or less degree of unconsciousness due to inactivity of the nervous system. Not only the avenues by which we receive

impressions are closed, but also the mechanism through which our various relations with the outer world are maintained and regulated, is cut off.

But not all organs sleep; some find other means to be equal to their duties. This variation is explained by the laws of differentiation.

All biologic functions must be studied in the simplest forms of life—the cells. The cell consists of a cell wall, plasm and a nucleus. But some living matter has been observed without a cell wall and even a nucleus can be missing. Thus in the simplest living being there is nothing but protoplasm, a network holding together a gelatin or fluid, and consisting of carbon, oxygen, hydrogen and nitrogen.

But life is not mere chemic change; it is rather chemic change in the services of the metaphysical principle of species which in juxtaposition develops the individual and in postposition creates the offspring. (Juxtaposition and postposition are inadequate terms, because the individual is not made, but precreated and developed.)

We must accept the metaphysical control for the following reasons:

1. Every cell and every organ in the human body is strictly typical in normal and pathologic condition; if forms are made under control, the forces producing them must first be controlled. Only such forms of energy are disengaged and so much of each as are in accord with the design.

2. There is a correlation between all functions under a central power.

3. Only certain substances are absorbed; matter absorbed either benefits or injures the cell; but to a certain degree of irritation the cell retains its integrity.

4. Intellectual and moral qualities of man can not be brought under the law of conservation of energy without acknowledging a metaphysical principle in close contact with matter and energy. *Cogito ergo sum* is the deduction of the general axiom; *species, ergo vivens*. Species creates the individual in abstracto and makes it the subject towards objects.

5. We perceive objects not as they are but as they affect our senses; but we get a correct perception over imperfect and faulty apparatus.

6. Only an organism can be sick and may recover health by maintaining the typical form, although chemically changed.

7. Transmission of changes and disorders from parents to offspring means only that species may suffer as well in postposition as in juxtaposition.

8. In nerves and muscles of a dead body, there is no disengagement of electricity and of mechanical force; but an unrestrained chemic dissolution takes place.

Both intellectual and animal life are manifestations of the same metaphysical principle. Type or species leads every disengagement of energy in organic action. But before we consider energy in its relation to matter and especially in its modifications in an organism we must call attention to a misunderstanding commonly met with, that forces act directly at a distance and that energy makes a round from masses to masses.

If it is true that where there is one substance there no other can be and that matter and energy can not be separated; then we may not use expressions as "free or communicated energy;" energy being inherent to matter can be active and disengaged only. Light is communicated neither to the eye nor to the

rock, but disengages energy although differently in the eye and in the rock. Furthermore it must be emphatically said, that disengaged energy is not the real cause of a phenomenon, but that cause is within a thing and only the inciting cause is from without; but disengaging and disengaged energies combined constitute the phenomenon. Simple as these assertions may seem to be, they are essential in our conceptions and their disavowal has led to grave mistakes.

Energy in inanimate masses is disengaged with or without transformation or it is latent. In living organisms we observe the same conditions of disengagement but subject to the biologic laws of maintaining and of developing the type. In most cases disengagement goes on with a partial transformation that means the disengaging energy with that to be disengaged appearing in partly new forms. Warmth affecting wood disengages warmth and, partly, chemic change and light. But if transformation becomes the prominent feature, as in ignited gunpowder, we call disengaged energy adequate. The spark is the adequate energy of burning coal and sulphur and of decomposing saltpetre; warmth disengages chemic change. As a result of this chemic change, we receive substances whose energy is partly used in changing the aggregation of their molecules into gases. Gases disengage mechanical force by expansion. Expansion is mechanical force and is inadequate to the bullet, disengaging its energy without transformation.

But we have to assume a third condition of energy. A spark without gunpowder does not move the bullet; it disengages some warmth in the bullet but does not change its form or place. But as soon as warmth has accumulated to a certain degree, a part of it disappears, changing the aggregation of the molecules only to reappear in its original form when temperature goes below the known limits. This warmth on which aggregation depends has always been called latent, but in a wider sense all energy is in a state of latency if persistent and not disengaging. This must be said of chemic change forming physical bodies; there is a relative rest from which unrest of other energies may be judged. We speak of adequate, inadequate and latent energy only relatively to their prominence.

Comparing the same conditions in living organisms, I must confine myself to a few examples. Much moisture and warmth are required to disengage chemic change in a seed, but once started a metabolic grouping will continue in all substances absorbed by the cell. Light disengages electricity in the eye; light is the adequate energy for the substance in the optic nerve, as sound is for the ear, but neither is light to the ear nor sound to the eye adequate, although both are connected with nerves. But meanwhile a spark may ignite any quantity of gunpowder, and the disengagements in eye or ear are corresponding to intensity and quality of the irritation. To dead organs the same irritations are not adequate any more.

We find, also, inadequate energy active in the organism for absorbed food or poison. Assimilation in its various forms is preëminently such a disengagement; although a mere chemic changing, how manifold are the processes and products! A billiard ball rolls with the very force and in the very direction imparted; two substances put in a vial will surely

form the body expected. But what a variety of chemic combinations has been discovered by chemists and all consisting of but a few elements? Every organ furnishes its specific products, mostly beneficial, but sometimes injurious if not changed anew or eliminated. This grand display has caused a wonder at all times, and the fact that substances are produced not found in the physical world has led to the belief in a supervising force of chemic change as the real cause of life. But exposing this fallacy, our authorities restricted themselves to forms and phenomena, excluding all researches relative to essentials of life.

The third state of energy, that of latency, appears in organisms frequently so modified that instead of latency we better speak of energy at disposition. We observe in gland cells, for instance in the pancreas during the state of repose, granules accumulated which we may claim for some reasons not to be protoplasm, but the substance ready for a moment's call of an irritating nerve to be transformed into the specific product of the gland. Corresponding substances in muscles and nerves form the hypothetical stratum for an explanation of their activity. These substances represent energy at disposition.

Of the cosmic influences, or disengaged energies, our senses receive a few, but with a remarkable sensitiveness as to intensity and quality. Others, as electricity, we do not perceive; we feel heat and shock and notice light into which electricity has been converted, but not electricity itself. And light, the source of all life, is not disengaged at all in the human body as long as there is life within. This great restriction in disengaging energy we notice in every living cell in various ways protects life within certain limits and is the cause on one side of restoration after exhaustion and on the other of recovery after sickness. But all restriction ceases when life is extinguished and unrestrained physical laws prevail.

If we are inclined to accept a monistic conception of nature, in that sense that intellectual and animal life have the same origin, I feel satisfied to have shown by this discussion that species is really the principle of life. But to prove it by demonstration, I will proceed to the part of this essay dwelling on sleep.

The simplest living matter consists of protoplasm and an enlivening principle whose lower border line projecting in individuals is reflected in the organs of our senses.

Living matter assimilates, it absorbs substance, merges the material into other chemic groups similar to its own, and eliminates substances not useful to its design; living matter also proliferates, that means it separates and divides masses accumulated by assimilation in new forms like its own with a certain degree of independence.

Groups of cells develop to distinct forms and organs of a specific function as nerves, glands, bones, muscles and so on and these specific functions may become so prominent that assimilation seems to be rather an auxiliary action and that proliferation ceases entirely in certain tissues as in hairs, nails, blood. A mother tissue is necessary for the new formation of such tissue. This process is called metaplasia and is one of the results of differentiation.

Differentiation of tissue as well as of organs causes their independence to yield to a central power with the

result of a more distinct individuality of the organism as a whole. But dependence of tissue and organs, and the more marked individuality of the whole organism make a shifting from variety to a new species difficult and impossible. Virchow says: "Darwinism has no room in pathologic anatomy of man."

Assimilation and proliferation are really the prerogatives in living matters towards inanimate masses as crystals. They are the fundamental functions of life in the simplest forms as well as in the most complicated organisms; they are active in all organs of different and various specific functions which may explain the correlation of these functions and also the dependence of each from the whole. These various and different functions are specific and the result of differentiation as perception, motion, respiration, digestion, circulation and secretion.

All these specific functions have in common the tendency to bring assimilation and proliferation in contact with the outer world, under most favorable conditions, and the means of accomplishing this are the organs.

The external influences are either substance in form of food, drink or air (latent energy in a general sense) or disengaged energy in its origin either directly or indirectly cosmic. Latent energy or food, drink or air entering the body begins a chemic change and means a plus to the household which interchanging gradually diminishes.

There are connective, muscular, glandular and nerve tissues in the human body and each with various metaplastics, and besides this a procreative tissue in the sexual organs. These five mother tissues maintain their character even in metaplastics, but nourishing will be different in mother tissue and metaplastics. Another difference will arise from the specific functions. The glandular cell produces, for instance, trypsinogen, glycogen and so on, the muscular fiber, inogen, both to be disengaged with or without transformation. For muscular tissue it may be an explosion or a process similar to bulging, dividing and separating in proliferation. But for nerves the primordial substance must be produced by their respective cells or mother tissue which on irritation appears instantaneously in an electric nature. For this reason we assume molecules constituting nerve substance to be homogeneous and their electricity to be latent, as warmth is latent in fluids and gases. Therefore their energy is excitable in an instant. Certainly there is not an electric current in nerves. Nerves have lost their individuality as hair, nails and blood have; but their neutrality enables them to be carriers of irritation.

The next conclusion will be that neither nerves nor blood have scientifically the prominence in the household of man that is asserted in our text-books. The latter distributes food or latent energy, and the former cosmic irritation or active energy; both maintain a neutrality but of the greatest importance. The fundamental functions of life rest in the mother tissues. The weakness of both the humoral and neuropathology is manifest. Blood and nerves are the routes our therapeutics take, but our attacks must be directed to assimilating and proliferating tissue.

Of the forms of disengaged energy from without, some are received by our senses and are answered by a reaction of electrical polarization. Soon the whole

nerve is placed in a state of electric irritation, a "nerve-current" is formed and this irritation is carried to the central organ and from there on other roads back through the whole system especially to muscles, glands and so on.

As we observe in simple organisms, as in hydra, an endoderm absorbing food and an exoderm receiving irritating energy, so we have two systems for the same purpose in higher differentiated organisms.

But organs receiving disengaged energy become exhausted periodically, according to the law of conservation of energy, require rest and are restored by rest. This is the standpoint we have to assume in judging exhaustion leading to sleep.

Herbs and animals fit themselves to the surroundings and protect themselves in order of self-sustenance and development. This tendency is also expressed by differentiation.

Individuation begins with formation of organs, for protection of which in the development of man the greater part is cast off. I mean the fetal membranes. But the remaining part, the skin, serves as a coat of mail and an exit for excretions, and at the same time gives space to peripheral receivers of the organs of perception remotely located. But no other, unless disengaged energy, and only one form and a certain form, finds an entrance at each receiving place; thus light is referred to the eyes, mechanical force to ears and fingers, chemic change to nose and tongue; meanwhile millions of sentinels are dispersed all over the surface, the filaments of cutaneous nerves. For warmth we have no special sense and not for electricity. What a contrast the human skin presents! Impermeable to all substances and influences as long as it is unhurt, the skin is the bearer of apparatus sensible to all grades of quality and intensity of energy from near and far.

Energy of the sun excites electric vibrations of the ether, which, entering the atmosphere, are transformed into light and reach us either directly or reflecting from the surrounding world as color, sound, motion, warmth and so on. These relations to the outer world are the cause of the variation of the body, of its gain intellectually, and of its loss bodily and certainly of our intellectual and moral life.

But on the other side we observe that the functions of the kidneys are more important to health than those of our eyes, and the activity of the stomach and liver more necessary to life than the senses of smell and taste. Indeed we may miss these organs without being aware of the want.

Assimilation and proliferation are good house-keepers, caring less for earning than for managing the earnings. But in earning, expenses are made.

The internal organs, those as well of perception and motion as all specifically active in assimilation in the wide sense, are not simultaneously or equally developed, neither do they reach an equal perfection. Some organs belong to fetal life only, others to a late period in life; the most constant organ is the heart, the first and last in action.

The law of conservation of energy teaches us that we perceive but variations of things and that all phenomena are the result of various forms of the same energy. Only gravitation will not submit to this law, but according to Helmholtz, gravitation or universal pressure is the source of all energies to be considered both in physics and biology.

The quantity of heat necessary to raise the tem-

perature of a kilogramme of water one centigrade is called a unit of heat. Any kind of mechanical work, compression, percussion or friction of bodies produces heat; the mechanical work necessary to produce a unit of heat is the mechanical equivalent of heat. The amount of electricity necessary to produce a unit of heat would be the electrical equivalent of heat.

The mechanical equivalent of heat is known by experiments to be 424, that is a power which would raise a kilogramme of water 424 meters or 424 kilogrammes of water one meter will also raise the temperature of a kilogramme of water one centigrade.

But equivalents are less important for our purpose, because we can not yet consider phenomena of life from a mathematical aspect. If we only know that no energy is lost but that it disappears entirely in one form before it reappears in another, and that the substance after a disengagement is not fit for a disengagement in the same form; then we are enabled to explain how a controlling power may prevent overheating, combustion and decomposition and inducing absorption; how it may lead molecules into certain homogeneous chemic groups, and how these processes influenced from without and repeated a thousand fold in every instant may be carried on here and there in various ways, but uniform and conforming to the whole.

Blood is a metaplastic tissue; we did not observe so far a proliferation of blood cells. The red corpuscles have neither a membrane, nor nucleus and being solid are no cells; their new formation requires a mother tissue. Therefore we can not speak of blood diseases. Blood is a neutral fluid; it may be contaminated as a stream is polluted by surroundings; but it does not contaminate itself. This peculiarity qualifies blood so well as a carrier of food. The chemic interchange is diminished to a minimum on account of its metaplastic nature; oxygen is absorbed by the red corpuscles as charcoal absorbs gases and is carried to all organs and especially to the brain where it is mostly needed; opium and other poisons are transported over this route to distinct cells of the brain where a chemic change may take place with the result of paralysis; the product of the thyroid gland takes the same means of transportation to the brain. At least we can not find any other cause for the degeneration of the brain where the organism is deprived of this gland. Perhaps prohibition of chemic interchange may explain also the germicidal power of blood serum.

Blood heat, although remarkable for its stability and warmth of the whole body seems to be overrated in its importance to the economy. Fever heat indicates only that chemic change is disturbed. Danger arises from this disturbance exclusively.

Chemic interchanging begins in the tissue proper and assumes such complicated and variable appearances that only a few facts can be ascertained. Of food ingested, air, water and solubles enter the organism in a purely osmotic way, but not without an exchange. The exchanged substances loosen chemic groups in the food, without thus rendering them resorbable at stations beyond; this may be repeated, leaving finally waste matter only.

Substances absorbed begin an endless series of metabolic changes. We must assume that these chemic changes are as strictly controlled as production of heat is or any other transformation. Assimilation is

mainly chemic change of accumulated masses which slowly decrease to end with elimination of wastings through kidneys, skin and lungs. But we must keep in mind that all processes take place in cells and that their inciting cause, be it from a neighboring cell or a microbe or poison is controlled by physical laws only; biologic control belongs to reaction in the cell exclusively. Every cell acts as a relative individual, prospers and suffers or remains indifferent to irritations of neighbors. But to remain indifferent means in biology to be protected; protection is within certain limits towards normal and pathologic irritation. At times the constitution of the plasm is weakened, some chemic groups can be loosened easier, or certain substances in the blood have a peculiar influence on distinct groups. For this reason they are termed poisons or medicines; then the reaction in the plasm becomes abnormal and the inciting cause with the reaction in the cell results in a condition which we call sickness or disease.

In general, we construct the law of conservation of energy as follows: In nearly every disengagement there is transformation present; disengaging energy of higher intensity disengages so much more energy of another form, and in the contrary absorbs so much that the functions of the quantities before and after the disengagement are not altered; both energies before the disengagement are equal to the energy afterward in the new form. Practically we say, what is loss to one organ is gain to another. We can at least understand that there is not so much loss of substance on account of assimilation, but that metaplastic tissue being practically eliminated from the economy, and although of greater stability, increases consumption and wasting in the mother tissue.

It becomes now our duty to demonstrate consumption and wasting in the nervous system. As blood is the carrier of food to assimilating and proliferating tissues, especially qualified by its metaplastic nature and a neutral distributor of food to all organs, so cosmic influences affecting our senses as color, sound, motion, pressure and so on, are transferred by carriers equally neutral, the nerves. We assume a metaplastic origin for the nerves, too, because they grow from the nerve center and are new formed from there. And as blood is transported to a central station to be distributed from there to all districts, so all irritation by disengaged energy from without is sent through sensory nerves to the brain, to be followed by orders to muscles, glands and so on.

There are vital railways and telegraphs in the organism. But there is still another conformity, in the receiving stations. Teeth, saliva, gastric juice and others act upon food, and adapt it for absorption, but the apparatus of our senses does the same with irritation of cosmic influences. Light does not affect directly the optic nerve, nor does sound irritate the nerve of hearing, and certainly the nerves of smell and taste may not be incited unless a receiving apparatus has selected carefully the form and quality of disengaged energy and has adapted it to the respective nerve. How would it be possible that nose and tongue can discriminate, when chemist and microscopist have already reached the limits of their skill! How light, sound and odors are delivered to sensory nerves we do not know. The veil is partly raised from the finer structures of retina and labyrinth, but we do not understand the wonderful pictures.

Is visual purple analogous to gastric juice in transforming light into electric irritability? We know the nerve to be a good carrier of irritation on account of its metaplastic nature, but we only presume the form of its disengaged energy to be of the electrical kind, a polarization, termed "nerve current" but not an electric current. I have to repeat yet with emphasis, that blood and nerve have a great stability of their own and that they can not become sick; their normal and abnormal conditions depend entirely upon their respective mother tissue and the surroundings, just as hair and nails do not contract a malady but suffer with the disordered mother tissue.

Nerve irritation is conveyed to the nerve cell to reappear there in a new transformation. But we have to attribute two metaplastic processes to the nerve cell; one as we have seen in the formation of nerve substance and the other in the production of little corpuscles similar to trypsinogen and glycogen which, on nerve irritation, appear as the specific products of the cerebral cells. Their existence is not yet proved by direct observation, but is highly probable according to conclusion by analogy. Every irritation must leave a permanent impression on the products of the cerebral cells; these imprints affecting mind are repeatedly tested, selected, arranged and preserved. Whether the same nerve cell produces nerve substances and these corpuscles, and how the processes in cells and filaments are carried on we do not know.

But we may understand somewhat of the magnitude and diversity of their work when we are informed that the brain contains 600,000,000 of nerve cells and twice and thrice as many filaments connecting them, and if we join anatomy with physiologic activity we take into consideration that many irritations are required for the conception of light, and many more to get the idea of green, of shape, of leaf, of growth and of life, and that the endless series of irritations must be tested, selected, arranged and preserved. These imprints must be regarded as eliminated from the economy because they are metaplastics. We are aware now of the great consumption and loss resulting from their production. Exhaustion is the natural consequence; but nerve cells do not differ in this from other mother tissue. The difference rests in their restoration only.

Nerve irritation is adequate energy to the corpuscles produced by the cell, but not to the plasm maintaining the same. Repeated irritation and over-exertion produce hyperemia and swelling connective tissue, but no impressions in the exhausted cell. Its specific activity ceases.

The exhausted cell is not specifically active, as the nail does not grow in case of fracture of the limb because the connective tissue (in a general sense) is engaged in producing a callus. But there are other factors checking activity of the brain cell, also, as impaired constitution of the plasm, interruption of nerve irritation, poison, shock, hypnosis. The cell in normal condition may be exhausted, but its integrity is not impaired. If there are different influences having the same effect, there must be another cause of sleep which is common to all and different from each. Sleeplessness during nervous excitement, and in neurasthenics, dreams and so on, indicate that periodical exhaustion does not more than induce sleep.

Many animals go well fed into a winter sleep.

Certain fishes and amphibia sleep in a similar way during the dry season. Dr. Fred Cook, of the Peary expedition, reports that Eskimos are in a semi-comatose condition during the night of several months, that menstruation ceases, that all births are counted from the time of the reappearing sun and that nevertheless they sleep every twelve hours although not exhausted. The temperature of their blood is half a degree higher than ours. And then we know that quietness, darkness and coolness have much to do with sound sleep. All these facts convince us that exhaustion in the cell induces sleep, but that the cell, self-ruling, demands sleep and it puts itself asleep. Sleep is really to be compared with other resources of nature maintaining welfare and life; as hypertrophy, vicarious functions of skin, lungs and kidneys, the changing fur in winter and so on. Muscles hypertrophy in official duty and their action is *en masse*, but nerve cells, active individuals, find relief only in periodical rest.

Pflueger maintained the theory that brain cells are very sensitive to want of oxygen and that this want is the cause of sleep. This theoretical conception is in contradiction with many facts, and it will be necessary to go into details to reach a proper understanding. The plasm of cerebral cells is probably not more sensitive to a want of oxygen than in other cells, but this want seems to be felt mostly at the disengagement in their products forming "imprints."

The condition of the blood has much to do with our mental activity and, on the other side, hard brain-work influences the quality of the blood.

Full blooded youth is intellectually fresher and needs more sleep than the dry stupid senile. He who sleeps dines. Methodical reasoning is less tiresome; clear thinkers as Lessing, do not dream; all such assertions connect with the idea that supply and consumption of blood are in a causative relation to our capability of perceiving and reasoning. But if our thinking should depend on the supply of oxygen exclusively, then the full blooded would be our philosophers and the pale and lean would pass in sleeping the time for action. In fact, Pflueger asserts only, that sound and plentiful blood and especially its oxygen nourishes the cerebral cells. But if we say, these cells feel a want of oxygen not in their sustenance but in their specific action, then all contradictions mentioned above are dissolved and this theory is placed in the right light excepting in one point. We have to place the cause of all vital phenomena in the cells, specifically active.

For this reason we adopt the following explanation of sleep: nerve irritation is followed by reaction in the cell with the result of granules, already separated, being transformed into the specific products; oxygen of the blood is required for this transformation and enters into this chemic change. Nerve irritation fixes the amount of oxygen and partly the quality of grouping. If the plasm be exhausted or the impressions too weak, then the product will be deficient and the imprints are either indistinct, unfit, or they are missing. A correct perception requires a well fed cell, a vigorous irritation and oxygen at disposition.

Besides removing some absurdities of the storing-up theory, our conception explains the objectivity that is in every perception. The impression of light is reaction of the cell and is subjective, but the perception of blue is an alteration due to the exciting cause and is objective. We comprehend also the

truth in the proverb, "he who sleeps dines." We also understand that full blooded youth demands more sleep than old age, and we find it correct that clear thinkers mature their thoughts and close up periodically to begin anew later. The cause of sleep rests in the cell; it puts itself asleep whether there be oxygen or not. Want of oxygen is not in nearer causation to sleep than want of irritation in repose, darkness and monotony.

We must bear in mind that every organ has a two fold function; one in its official capacity towards the organism and one in its private capacity for self-sustenance. We observe both functions increasing and decreasing in glands and muscles, not bound to periods; in others as in the heart and in the lungs there is work and self-preservation well compensating each other and consequently uninterrupted. But brain cells have only one resource of restoration and one way of caring for their welfare viz., periodical rest.

It is apparent now that we can not speak of sleep in the fetal brain, because it is active scarcely in any other way but in differentiating and in developing.

Want of oxygen being the cause of sleep is an easy formula of a mechanical conception of nature, but it is also a fair example of the shortcoming of such a conception. I refer to cases of total blindness and deafness as of Laura D. Bridgman, where the sense of touch was the only means of developing a bright intellect of wide range. If the human organism were a machine only, how could it be possible that intellectual powers could be unfolded in such a high degree when all avenues of communication with the outer world seem to be closed?

There is a miniature world within the human body that seeks a union with the greater world, and the organs of perception and motion are the means and ways to accomplish this. They are really the servants and if one fails another will be tried.

A result of the inactivity of the brain cell is unconsciousness in one direction and idleness of nerves and muscles in the other as a matter of fact. Yet all organs show a slower and weaker activity during sleep, but can we expect anything else from decreased or missing irritation?

Whether muscles sleep, may be decided by a few words. Muscles are real dynamos which mostly on nerve irritation transform chemic change into mechanical force; they are more or less in a constant tonus. Some muscles become exhausted and rest occasionally; thus they take a chance during sleep. Some others are never in a state of repose. But none, even if it should be in action now and then only, is, when exhausted, the cause of unconsciousness. Most of the muscles may rest but they do not sleep. Even nerve irritation is not necessary for all muscles. The heart contracts without any palpable excitation from without (confer Romberg, Berlin, *Klin. Woch.*, March 27, 1893, and JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, vol. XXII, No. 17). Sympathetic and pneumogastric nerves regulate only the heart's action.

About both motor and sensory nerves and their peripheral apparatus not much remains to be said. They are telegraph wires and apparatus; there is an equal loss in their wear and tear, whether in use or not, and consequently no periodical exhaustion.

The aim of viewing nearly the whole field of phy-

siology from a higher standpoint is to give it a wider scope and to bring abstraction again nearer to reality. The great gain that will be derived is that we will understand better the merits of functions and the value of symptoms; we learn weighing them.

If we are in doubt whether we should resort to intubation or tracheotomy, or to expectant treatment, the question arises, What is the worse, weakness of the heart, or want of air? Then we weigh symptoms; and to weigh them, constitution and vitality is practically more important than a detailed diagnosis.

## ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.  
NEW ORLEANS, LA.

(Continued from page 439.)

### CHAPTER VII.

**Lungs:** The lungs in the dependent portions were greatly congested with blood, and presented a mottled purplish and red appearance. The lower portions of the lungs, when cut, resembled the congested lungs of pneumonia, and in circumscribed portions effusions of blood had taken place.

The muscular structures of the thorax, when cut and exposed to the atmosphere, presented a brilliant scarlet hue, like those of patients poisoned with cyanid of potassium.

**Abdominal cavity:** Alimentary canal, exterior surface of stomach somewhat congested. Internal mucous membrane of a deep purplish and brownish-purple and red color, with variations in the depth of the color, presenting a mottled appearance. Under low magnifying powers, suitable for the examination of the mucous membrane of the stomach by direct light, an intense congestion of the capillaries and small blood vessels was observed.

In some places the epithelium of the mucous membrane of the stomach had been removed, and the capillaries were exposed and ruptured, and from the points of rupture issued small flakes or coagula of blood, resembling those so frequently found in black vomit. The epithelial cells of the mucous membrane were detached in large numbers; they could also be removed readily by slight and delicate scraping with a spatula.

**Black vomit:** The stomach contained one pint of black vomit, of a dark purplish color, resembling in all respects defibrinated and altered blood. Under the microscope, the black vomit was found to contain numerous colored blood corpuscles, variously altered, also cells from the mucous membrane of the stomach, and also broken capillaries. In this case the black vomit resembled in all respects blood which had been defibrinated and mixed with gastric juice, or with a mucoid fluid. This specimen of black vomit, taken from the stomach twelve hours after death, contained some fibers, and the sporules and thallus of a plant resembling the yeast plant. The yeast plant appears to be most abundant in the acid black vomit of life, and appears to be dependent in large measure for its rapid development upon the articles of food consumed. If much sugar be introduced into the stomach with the food, the growth of this plant is rapid in a stomach which has lost its muscular and diges-

tive power to a great extent. The sporules of these plants appear to be ever present in the atmosphere, and they increase rapidly whenever the proper conditions, as in the disabled stomach of yellow fever with its albuminous contents, exist for their growth and development. The odor of this specimen of black vomit was putrid and disgusting, resembling that of decomposing blood. When heated upon the sand-bath the odor emitted was very disgusting and overpowering, and excited nausea. Specific gravity of black vomit 1026. Reaction of black vomit alkaline. The surface of the mucous membrane of the stomach, as well as the black vomit itself, emitted strong fumes of ammonia, in the form of free ammonia, and its carbonate and sulphid. When a glass rod was dipped in strong hydrochloric acid and held over the mucous membrane of the stomach and over the black vomit, heavy dense fumes of chlorid of ammonium were evolved. The alkaline character of the black vomit was evidently due to the decomposition of the urea, and its elimination as carbonate of ammonia by the gastric mucous membrane. The black vomit was carefully tested for urea, and yielded this substance in considerable amount, as well as ammonia and its carbonate and sulphid.

Analysis of black vomit: Reaction alkaline; alkaline reaction dependent upon ammonia; emits heavy fumes of chlorid of ammonium in the presence of hydrochloric acid; specific gravity of black vomit 1026.

One thousand parts of black vomit contain:

Water. . . . .	906.00
Solid residue, 94.00	
Organic matters, 85.40	Albumin, colored blood corpuscles, mucous corpuscles and epithelial cells, 77.14
Saline matters, 8.60	Extracative matters, urea, ammonia, etc., 16.86.
	Organic matters. . . 75.46
	Saline matters. . . 1.68
	Urea, ammonia and fatty matters . . . 9.94
	Saline matters . . . 6.92

Still further to confirm the existence of blood in the black vomit, the ash derived from careful incineration was tested for iron, and was found to contain this substance in amount equal to that which would be found in 77 grains of blood.

Microscopic and chemic examination of blood from cavities of the heart: The blood from the cavities of the heart contained several loose, golden-colored fibrinous concretions. The blood was fluid and did not coagulate upon standing. The odor of the blood twelve hours after death was putrid, but not so disagreeable as the black vomit taken from the stomach after death. The colored blood corpuscles were crenated and altered in form in some instances; many of the corpuscles, however presented the usual appearance, while others were more round and smaller than in health. The blood from the cavities of the heart and from the large blood vessels contained numerous fibers. In twelve hours after death the blood manifested even within the heart itself the presence of living vibrating animalcules. Upon standing, these increased in numbers. They were also, as we have just seen, present in the black vomit of the stomach. The fibers must have been formed or originated in the following ways:

1. They existed in the blood before death, being received through the pulmonary apparatus. We can not adopt this view, because they are entirely absent from the fresh blood examined during the life of the patient.

2. They arose spontaneously in the blood after death, as a result of the putrefactive process. The

adoption of this view would involve the adoption of the theory of spontaneous generation, which, as far as our investigations have extended is, in the present state of our knowledge untenable.

3. They penetrated from the stomach into the blood, finding ample space for entrance through the broken capillaries and through the eroded surface of the gastric mucous membrane.

The germs of the fibers existed in the tissues during life, and even in a state of profound health. They were prevented from germinating by the chemic changes (compositions and decompositions) characteristic of health. After death they multiplied rapidly and found a ready entrance from the tissues into the blood vessel system through the pores of the capillaries and small veins, described by Conheim. These so-called stomata vary in size from 1-1000 to 1-10,000 of an inch in diameter; and if it be true that there are really openings or pores in the small veins, we have an explanation of the mode in which the minute vibrios might readily find entrance into the blood from the surrounding tissues. The surface of the blood from the heart presented an oily appearance, and the microscope showed the presence of minute globules. When a drop of the blood was allowed to fall upon a piece of white filtering paper, the center presented a bright red appearance from the presence of the colored corpuscles, while the central colored spot was surrounded by a bright red golden colored border.

The reaction of the blood from the cavities of the heart was acid.

Chemical analysis of the blood revealed similar results to those obtained during life; thus, the colored blood corpuscles were normal in amount; fibrin greatly diminished, and in fact entirely absent; bile and urea present in large amount. The fact that the fibrin was diminished even in the acid blood would establish the important fact that the diminution of this element in the yellow fever blood was real and not apparent, and dependent merely upon the presence of ammonia. The acid reaction of the blood appeared to have been the result of post-mortem change and may have been induced by the vibrios. The acid reaction may also have depended to a certain extent upon the relation of phosphoric and sulphuric acid and acid phosphates in the blood, in consequence of the arrest of the action of the kidneys. The brilliant scarlet color of the blood upon exposure to the atmosphere, and of the muscles of the thorax without such exposure, may be due to the presence of urea and phosphoric acid and acid phosphates, the accumulation of which in the blood was dependent upon the arrest of the function of the kidneys. To the same cause, that is the cessation of the action of the kidneys, must be referred the remarkable bloodiness of the tissues; the watery element of the blood is not properly removed by these organs and the blood vessels become in consequence, filled and distended with the altered blood. The passive hemorrhages observed in the various organs, stomach, lungs and even in the muscular structures, must be referred to the destruction of the fibrin of the blood and to the great destruction of the blood in virtue of the cessation of the action of the kidneys, liver and stomach. It results also from the same causes, viz.: The fluid character of the blood and the great distention of the blood vessel system with an abnormal amount of altered blood, so that when a canula is plunged into

and through the walls of the heart of a yellow fever subject, even hours after death, the blood will flow in a continuous stream through the canula, and some pints may thus be drawn off.

**Spleen:** Somewhat enlarged and softened. Weight ten ounces. Splenic pulp and structures changed readily and rapidly to the arterial hue when exposed to the oxygen of the atmosphere. Under the microscope, the splenic pulp was found to consist of altered red corpuscles, granular masses and numerous oil globules. The decoction of the spleen presented a brownish, purplish, reddish, mahogany hue, quite different from the golden hue of the decoction of the heart and liver. Upon chemic analysis the spleen contained both bile and urea.

**Liver:** The liver presented a yellow and brownish-yellow appearance. The portal system of capillaries appeared to be congested with blood. A few small slate-colored spots were observed upon its surface. The structures of the liver were firm and appeared to be firmer than in health; considerable force was required in mashing the structures in the wedgewood mortar previous to analysis. Upon analysis the liver yielded animal starch, grape sugar, urea in considerable amount. The decoction of the liver yielded urea to a less amount than the decoction of the brain. Under the microscope, the liver was found to be loaded with oil globules, and many of the cells were greatly distended with yellow oil. The oil globules were also deposited within the meshes of the fibrous tissue of the liver. Owing to the large amount of oil present within and around the liver cells, they were indistinct in their outlines. The accumulation of oil in the liver was undoubted. The color of the liver, especially upon the cut surface, was that characteristic of yellow fever, and its consistence was as usual, also as is usual in this disease, increased. It would appear that albuminoid or fibroid granular matter transudes through the blood vessels of the liver, as through those of the kidney. It is probable that the peculiar alterations of the liver in yellow fever, cause obstruction to the free flow of blood through its hepatic and portal veins and capillaries, and in such obstruction we may find some explanation of the congested portal circulation, and even of the gastro-intestinal hemorrhage, or at least a favorable condition to its establishment.

**Bile:** Specific gravity of the bile from the gall bladder, 1040. The bile presented a dirty, greenish-yellow hue, was thick and grumous, and under the microscope was found to contain numerous cells of the mucous membrane of the gall bladder. Mucous membrane of gall bladder deeply congested, and at the same time discolored by bile. When viewed in mass the bile presented a greenish-black color. It was highly concentrated; a few drops being sufficient to color of a golden color half a gallon or more of water. As is usual in yellow fever, the amount of bile in the gall bladder was small, only 120 grains being obtained. This diminution of bile appears to be characteristic of yellow fever; the gall bladder as a general rule is small and contracted, and contains a small amount of bile, rarely exceeding 150 grains, and rarely not reaching 90 grains in intermittent, remittent, pernicious and malarial hemorrhagic fever, and in typhoid fever, on the other hand, the bile is more abundant; and as a general rule the gall bladder after death is distended with bile. In yellow fever, bile is also absent from the intestinal

canal, and it would appear from these facts, as well as from the jaundice of yellow fever, that in this disease there is an occlusion of the hepatic ducts, in a manner similar to the occlusion of the excretory ducts of the kidneys.

Result of chemic examination of bile: Specific gravity of bile, 1040. The specific gravity of the bile was above that of the serum. Did not coagulate by heat. The proper reagents failed in producing any crystalline constituents.

Solid residue in 120 grains of bile:

Water " " 1000 " " " " . . . . .					869.50

**Kidneys:** Weight of kidneys, ten ounces. Kidneys congested on the exterior, more especially in the cortical portion, but of a more decided yellow color than in the kidneys of health. When sections were made the kidneys presented a yellowish color, resembling kidneys undergoing fatty degeneration. The kidneys, with the exception of a few circumscribed, small slate-colored spots upon the exterior, presented an appearance and color similar to that of the heart and liver. Under the microscope, the excretory cells and tubuli uriniferi of the kidney were found to be loaded with oil globules and granular, fibroid and albuminoid matter. The oil globules were diffused throughout the excretory cells, tubuli uriniferi, Malpighian corpuscles and fibrous textures of the kidney. The arrest of the urinary excretion, appeared, after prolonged and careful microscopic examination of sections of the kidney, with Valentin's knife, to have been due to the filling up of the Malpighian corpuscles and tubuli uriniferi and excretory cells with oil globules and granular, albuminoid or fibroid matter; and also to the stagnation and conglomeration of the colored blood corpuscles in the delicate capillaries of the kidney. The capillaries of the kidneys were filled with colored blood corpuscles.

The bladder contained no urine, and it was evident that the patient had not excreted any urine during the last forty-eight hours of life, and many of the symptoms during life were without doubt due to the arrest of the urinary secretion.

We have thus presented the results of the laborious and careful investigation of this case, which required my undivided attention for the entire period in which it was under observation, to the exclusion of all other business or interruption, with the exception of a few hours devoted to sleep and meals, not exceeding seven hours out of the twenty-four, each day, the remaining seventeen being devoted to the investigation; in order that a true picture might be presented of the relations of the changes of the blood to those of the various organs. Each case studied in this manner becomes a living exponent and demonstration of the nature of the disease, just as the description of one animal will to a great extent serve as the accurate description of the entire species to which it belongs.

*Case 2.*—Charles Collingberg; native of Iowa; attacked with yellow fever July 30, 1871; died in Charity Hospital after the supervention of black vomit August 4. Came to New Orleans four weeks previously; occupation, flat-boatman. Supposed to have contracted the fever on the bark *Mary Pratt*, from Cienfuegos, which had arrived a short time before with sugar. Is said to have slept for four nights previous to his attack upon the *Mary Pratt*.

According to official reports, this was the first case of yellow fever which occurred in this city during the

summer of 1871. Although the number of cases of yellow fever which occurred in the summer and fall of 1871 was small, yet the disease appeared to be of a violent and fatal nature; thus up to October 6, out of thirty-seven cases, which occurred during the preceding sixty-nine days, sixteen terminated fatally, thus giving a mortality of 43.2 per cent.; and the active and fatal character of the disease was still further manifest in its comparatively short duration; thus of these sixteen fatal cases, one terminated on the third day; one on the fourth; two on the fifth; five on the sixth; four on the seventh; one on the eighth; one on the ninth, and one on the sixteenth day.

According to the official reports of the Board of Health, 114 well marked cases of yellow fever occurred from the date of the first case, July 30, to that of the last, December 18, and of this number fifty-five terminated fatally; that is the mortality reached the extraordinary figure of one death in 2.07 cases, or 48.24 per cent.

In the case now under consideration, (Geo C. Collingberg) the blood from the cavities of the heart, as well as the black vomit, and the structures of the heart, liver and kidneys were subjected to careful microscopic examination, a few hours after death. The blood from the heart presented the characteristic golden colored areola, when dropped upon bibulous paper, and under the microscope the colored blood corpuscles presented a crenated and stellate appearance. No animalculæ or sporules, or vegetable organisms were observed, even under the highest powers of the microscope. Numerous vibrios were observed in the black vomit taken from the stomach after death. The muscular structures of the heart presented a pale, yellowish-brown, flabby appearance and contained much free oil in the form of globules. The liver presented the characteristic yellow color, and contained much oil, deposited in the form of oil globules in and around the secretory cells of this organ. The kidneys presented a yellowish-brown color, and the excretory tubes were filled with yellow granular matter. I injected, by means of a syringe, (the nozzle of which was plunged through the skin) into the cellular tissue of an active dog both black vomit from the stomach and fluid blood from the cavities of the heart, and also applied the black vomit to the mucous membrane of the eyes. The animal also swallowed a portion of black vomit and blood, after fasting. No ill effects were observed and the animal remained apparently well and active.

In the case of Newton Simpson, who was attacked on Oct. 11, 1871, and died with urinary suppression and profuse black vomit, on the ninth day of the disease, the textures of the body, divided by the knife, presented the bloody appearance usual in such cases of yellow fever; urea was detected in the blood, brain and liver. The heart contained in all its cavities dark fluid blood, which gave an acid reaction at the time of the post-mortem examination, ten hours after death. Under the microscope, many of the blood corpuscles presented a crenated, wrinkled appearance, others were swollen, while others again presented the usual appearance.

I could after careful examination, with high powers, detach no animalculæ, or simple vegetable or animal forms, although the search was conducted with great care, with powers of various degrees, from one-fourth to one-eighteenth of an inch objectives, and the highest

oculars. The blood was fluid, with little or no fibrin, and no fibrinous clots; the fibrin was in so small an amount, and in such a soft and unstable condition that it was impossible to determine the quantity. Specific gravity of blood 1046.

1,000 parts of blood from the cavities of the heart contained:

Water . . . . .	852.70
Solid residue . . . . .	147.30
Fibrin . . . . .	Traces.
Saline constituents . . . . .	9.80

From experiments which I have conducted, it appears that the specific gravity of the blood in the cavities of the heart after death from yellow fever is less than that contained in the large blood vessels. This appears to be due to the fact that the heart continues to circulate the blood, or to force it through its cavities during the last moments of life, the red blood corpuscles are arrested in the capillaries, and only the more tenacious constituents of the blood are returned to its cavities during the last moments of life. In this case, the spleen was somewhat enlarged and softened, and its "pulp" consisted of numerous colored corpuscles, oil globules and granular masses; but no living animalculæ or vegetable forms were observed. Blood corpuscles of spleen not specially altered in appearance. Oil globules abundant in spleen.

The reaction of the blood from the liver was acid, and at the end of twenty-four hours numerous prismatic crystals, of the triple phosphate of lime, magnesia and ammonia formed in the fluid oozing from the cut surface of the liver. The blood of the liver contained numerous oil globules, but no specific animalculæ or vegetable organisms.

The results of the microscopic examinations of the structures of the heart, liver and kidneys were similar to those detailed in the report of the case of John Allen.

In the case of Jacob Siegarist, age 26, native of Germany, who was attacked Oct. 12, 1871, and who suffered with well marked yellow fever, characterized by suppression of urine and alkaline black vomit, and who died on the seventeenth day of the disease, urea and bile were found in the blood and in all the organs, brain, liver, spleen and heart. At the necropsy, performed three hours after death, both cavities of the heart contained warm fluid blood, which gave a slight acid reaction to litmus blue paper and upon standing coagulated, forming a soft gelatinous clot which possessed no contractile power. The aorta, vena cava and pulmonary veins in like manner contained warm fluid blood, which coagulated imperfectly upon standing.

(To be continued.)

## APPENDICITIS.

DEDUCTIONS FROM TWO HUNDRED AND SEVEN CASES OPERATED ON, WITH TABULATED REPORT.

Read before the Chicago Pathological Society, Dec. 10, 1894.

BY JOHN B. MURPHY, M.D.

CHICAGO.

Professor of Surgery and Clinical Surgery, College of Physicians and Surgeons, Chicago; Professor of Surgery, Post-Graduate Medical School and Hospital; Attending Surgeon to Cook County Hospital; Attending Surgeon to Alexian Brothers' Hospital; Consulting Surgeon to Hospital for Crippled Children, etc.

(Continued from page 437.)

I will endeavor to give a short outline of the various conditions found in operating for appendicitis:

1. Where the abdominal wall is infiltrated, and the abscess is opened without opening the unaffected portion of the peritoneum, there may be: *a*, a small circumscribed abscess with the appendix forming part of the wall; *b*, a small abscess with a tract leading to a larger abscess deeper; *c* a large abscess filling the iliac fossa, containing fecal concretions, or a gangrenous appendix floating in pus, all closed in with firm adhesions. (This condition never exists in the early stage, and in this class of cases the adhesions protecting the peritoneum should not be broken to remove the appendix); *d*, there may be multiple abscesses with no connecting sinuses. This is a comparatively rare condition. In one of my cases, a second abscess was not opened and the patient died of pyemia four weeks later; *e*, there may be an abscess in the opposite side of the abdomen; it usually appears in the same relative position to the left anterior superior spinous process as the abscess does to the right. There is no connecting sinus. It never occurs in early cases, and is more commonly found a week after operation and three or four weeks after the onset of attack, and should be opened and drained.

2. In another class of cases, where the peritoneum is opened and no adhesions to the anterior abdominal wall found, a circumscribed abscess may be found situated on the posterior wall of the abdomen, over the promontory of sacrum and the appendix and pus surrounded and walled in by adherent omentum and intestine. This is the most common condition found in the early stage. The location of the abscess may be near the median line, near the margin of the pelvis, close to the crest of the ileum, over the kidney, posterior to the cecum, or on the margin of the liver, as in two cases. The occurrence of a suppurating appendix on the surface of the liver or adherent to its margin is due to the congenital deformity and malposition of the cecum, so perfectly described by Cushman, and the distension of the colon with gas does not aid in making a differential diagnosis between appendicitis and cholecystitis. Still the most frequent location for the appendix is in the neighborhood of the McBurney point. The exact position of the appendix can be found by following the white fibrous bands along the convex surface of the cecum to the base of the appendix. In all of these cases the field of operation should be thoroughly protected by carefully packing with strands of iodoform gauze, retaining the ends outside. The adhesions are separated, the pus sponged out and the appendix liberated from its adhesions; a ligature is then placed on the appendix, and one on its mesentery. In all the cases where the peritoneal cavity is opened directly, the appendix should be removed. Where the appendix is situated above and behind the cecum, in close proximity to the liver, the induration can be detected behind the cecum, and must be reached by pressing the cecum forward, packing around and opening the abscess, locating the appendix and removing it.

3. Where the abscess is circumscribed in the pelvis, and the appendix is found hanging over the brim or attached to the uterus, tubes or ovaries, the appendix is located by following the bands on the cecum; pus sponged out, appendix amputated and a long glass drain inserted.

4. In another class of cases the peritoneal cavity will be found to contain a large quantity of free pus with no limiting adhesions, the bowel may be smooth

and glossy, not in the least congested or eroded of its endothelium. All of these cases recover. On the other hand, the bowel may have a livid blistered appearance, entirely excoriated of its endothelium, and very much distended, showing a paralysis of its muscular wall. The great majority of these cases die. In either of the above cases, the appendix may be adherent or free; it is usually perforated and gangrenous. In both, the appendix is located by the fibrous bands on the cecum or by the sensation to the touch by its swollen, hard and enlarged condition; it must not be confounded with the indurated omentum. Extensive drainage, both of glass and gauze, should be employed, and no irrigation.

5. We find a class of cases when there is a small quantity of pus located around the appendix, with partial adhesions protecting the peritoneum and with flakes of lymph extending some distance. This condition may be caused by a perforation of the appendix; by a gangrene of the mucous membrane, local or general, without perforation; by a simple ulcer of appendix without perforation; by accumulation and retention of muco-purulent material in the appendix, with only an abrasion of the mucous membrane of that organ.

6. Specific ulcers in the appendix without perforation or infection of peritoneum, as: *a*, tubercular, of which we had one case with recovery; *b*, typhoid, three cases, all recovered. Both of the latter conditions produce all of the acute symptoms, pain, vomiting, tympanites and elevation of temperature. But with the typhoid, prodromal symptoms and marked elevation of temperature exist *before* the pain, nausea and vomiting. In these cases when the appendix is located at the time of operation it will be found very much enlarged at seat of ulceration, with the distal end distended with accumulations.

7. A class of cases when the canal of the appendix is partially or completely obliterated, or a stenosis of the canal is produced sufficient to cause retention of material in distal end, causing recurrent attacks. In one of the cases of this kind there was a fecal stone entirely surrounded by connective tissue, the mucous membrane having been completely destroyed and the canal obliterated in a previous attack; there were no adhesions around the appendix. In many other cases portions of the canal were found obliterated and in others a stenosis or narrowing of the canal; the latter is the most annoying variety, as there are frequent recurrences of attacks, and the patient is rarely ever free from pain or sensitiveness in that region. As far as I can learn from the literature, the credit belongs to Dr. Henry O. Marcy, of Boston, for being the first to perform the operation of appendicectomy in the intermediate stage for the relief of this class of cases. The operation was on Dr. Samuel B. Nelson, Nov. 9, 1886, and the report was published in the *Boston Medical and Surgical Journal* at that time. The patient recovered and left the hospital in eighteen days.

8. Appendicitis stercoralis: In this class of cases there is a large accumulation of feces surrounded by mucus or muco-purulent secretion. The attacks of pain are severe and recur frequently. They are usually accompanied by a temperature not exceeding 100 or 100.5 degrees, and vomiting is a very pronounced symptom. The attack resembles one of intestinal retention, as frequently a movement of the bowels can not be produced for four or five days. The cause of the symptoms of intestinal obstruction has not been

clearly explained, but I believe it a reflex phenomenon, as we have exactly the same symptoms produced in obstruction of the ductus cysticus with gall stone. The appendix in cases of this kind is very much enlarged at the distal end—small at the proximal; its mucous membrane is thickened and contains a large quantity of hardened feces.

The mortality in my cases, including all grades, and operating on every case of appendicitis, favorable or otherwise, which came under my observation, is 9.93 per cent. Total number of cases operated to date 207. The following is a tabulated form of the cases operated on since my last publication, March, 1894:

In the literature of this subject, I wish to call attention particularly to the contributions, each presenting various phases of the disease to a greater advantage than the other, of McFadden Gaston, Kraft, McBurney, Fowler, Maurice Richardson, Bryant, Shrady, Wyeth, Sonnenburg, Robt. T. Morris, Senn and McArthur.

#### DISCUSSION.

DR. D. W. GRAHAM—In making a post-mortem a few weeks ago, searching for the cause of death, the appendix was examined and it was a good illustration of what we might call an abnormally developed appendix seven inches long. It was not bent on itself but was lying between the abdominal wall and the ascending colon, the end resting against the liver, over the kidney, and was perfectly normal in structure. It hardly had a mesentery at all, but was simply embedded in the peritoneum, at the line of reflection from the large intestine, on to the abdominal wall, and was perfectly straight.

I am satisfied that we have an anatomical deviation from what is called the average normal size and position of the appendix more frequently than is generally supposed, and I am satisfied also that it accounts for many cases which seem to be very erratic in behavior. Those cases, for instance, which Dr. Murphy has described where the abscess appears on the left side, I believe are accounted for by an abnormally long, displaced appendix. If the appendix I have described had become inflamed and an abscess had formed about its tip the abscess would have been in close connection with the liver and kidney, so that the most probable diagnosis would have been abscess in connection with the liver, or a perinephritic abscess. I recall a case where the attending physician had made a diagnosis of suppuration of the liver where the early history seemed to point to the appendix, but an abscess could be made out. I did not make any exploration but simply opened a large abscess and drained and in the course of two or three days the usual fecal stone appeared, showing that it was a case of appendicitis and perforation. I think more attention should be paid to the point I have mentioned, in studying the pathologic anatomy of appendicitis.

DR. A. I. BOUFFLEUR—It is somewhat gratifying to note that we are gradually coming around to a position where we admit that we do not know very much about what we have to deal with when we have a case of appendicitis, and we must also admit that we do not know when we should operate, unless it be immediately, as soon as we recognize the case as one of appendicitis. I think it is generally the case now that surgeons, especially, will admit that there is no such thing as stating what appendix is going to slough off, become neurotic and perforate, or what one is going to recover. Such being the case we have a good deal yet to look forward to in the line of the true conditions present in the different cases. That we may hope some time to be able to distinguish clinically between a catarrhal appendicitis and a destructive form of appendicitis is certainly something we must look forward to with considerable pleasure, but that we will ever reach that status I am not now thoroughly convinced. The specimens Dr. Murphy presents to us this evening are illustrative of some of the conditions from a pathologic standpoint which I think would bear a little further consideration in addition to that given by him. In the first case, the one in the large bottle, we have an appendix of reasonable length which is not especially thickened but has at the distal part about an inch of the surface of the mucous membrane which is distinctly necrotic. Now the reason for this necrosis is that there has been a thrombosis of the artery which supplies the appendix, which according to Fowler is usually a terminal artery or there has

been a very intense inflammation which is always of microbic origin. If a thrombus forms in this artery we are sure to have destruction of the appendix beyond that point. Sometimes the artery goes to the end without giving off branches and then returns, in which case we will have destructive necrosis between the point of obstruction and the base of the appendix. When we have a case before us we do not know, whether in the course of a few hours that mucous membrane will necrose from the intense inflammation, or necrose as a secondary process to the obstruction of that vessel; and as a matter of fact it does not matter much, because both usually result in perforation and serious trouble. The next specimen calls up the inevitable stone, which as a matter of fact probably, plays a very small part in the production of appendicitis. I think the stone theory of appendicitis is losing ground rapidly. While it is present quite frequently yet it by no means has the prominence it formerly had in the production of this disease. It is asserted that the stone causes necrosis simply by pressure. The ordinary collection of feces which we find is so soft and small, compared to the lumen of the tube it could not possibly cause destruction in that way, but occasionally we do find one large enough and hard enough to cause pressure necrosis. The percentage of these little collections of feces that are hard enough to cause pressure atrophy is so small, according to Fowler, that we may look upon that as being practically no special cause at all. Furthermore, if you will take occasion to examine the appendix in laparotomies where it is supposed to be normal, you will find in the large majority of appendices these small collections of feces, without any symptoms of appendicitis. The third specimen, the recurrent one, I think is a very good illustration of what some prominent Eastern operator has found in cases of recurrent appendicitis, namely, that it is a parietal inflammation; in other words, there is more than the mucous membrane involved. Dr. Murphy spoke of this as a catarrhal inflammation, which is probably true of the mucous membrane, but here there is also, from uveal inspection through the bottle, considerable thickening of the interstitial tissue of the wall. In that case we have what is described as the second stage of appendicitis, or at least that stage which is manifest in the recurrent type or interstitial form of appendicitis. In addition, we have the next stage with the peritoneum involved. This classification is a convenient one and we may in time be able to differentiate between the three anatomic forms, but since the wall of the appendix is so thin and the infection is usually intense, we have rapid involvement of all the coats of the appendix which not infrequently ends in destruction. In view of the fact that we are as yet unable to determine which case is going to terminate fatally within a few hours, and also that an operation, when delayed, is practically useless in these cases, the primary or early operation is gaining favor very rapidly, and as it can be safely performed under the ordinary circumstances surrounding one in a house, it has a great many things in its favor as a legitimate operation. It is an easy and safe procedure unless too much is attempted. Emphasis should be placed upon the fact that it is not always necessary to remove an appendix to relieve the emergency of your patient's condition. In cases attended with abscess formation the mere opening of the abscess with thorough drainage will tide the patient over the emergency condition and enable you to subsequently remove the appendix under much more favorable conditions and give the patient permanent relief with the least amount of danger. I have seen two cases in which I am convinced, had I let the appendix alone, merely draining at that time and at a subsequent time removed the appendix, I would have given my patient a much better chance for recovery from the primary trouble and ultimate recovery from the whole trouble.

Again, as to the point Dr. Graham makes, I would say that the position he mentions is one of the recognized normal positions of the appendix, posterior to the cecum. We have four or five positions recognized as being normal although some are quite rare, and that is the reason why we have a change in the location of the abscess cavity, but when the appendix is involved the change in the location of the pain is as a rule very slight, if the appendix is on the right side of the body; the first pain being generally referred to indefinite parts of the abdomen, the second pain being referred to what is called McBurney's point.

DR. LE COUNT—I was very much interested in the last case reported by Dr. Murphy, where the appendix laid behind the cecum underneath the peritoneum. In the great majority of cases the appendix lies in the true pelvis on the right side; less often it is found behind the cecum; two

or three times I have seen the appendix in the position mentioned, and one very rare location was interesting to me where the appendix was entirely extra-peritoneal in the mesentery of the small intestine where that joins the cecum. We were unable to find it except by cutting the bowel open and probing the opening of the appendix. In the majority of cases it possesses a mesentery of its own. In regard to the terminal artery of the appendix, it certainly is surprising that in this condition emboli are not found more frequently. In regard to the necrosis that occurs, it is nearly always due to the specific action of the organism and not to pressure. One condition noted by Dr. Murphy was the rarity of catarrhal appendicitis. The condition usually is not an inflammation of the mucous membrane but begins as a microscopic abscess in the submucosa, in the lymphatic elements that in other conditions act as filters, and seem to act that way here. A coalescence of these takes place in the submucosa and in the mucous coat. I have examined two or three appendices from cases that were clinically catarrhal appendicitis and in all of them these microscopic abscesses were found in the submucosa, a condition that could not be called, in a strict sense, catarrhal appendicitis.

Dr. H. N. MOYEA—When I was in general practice I saw, first and last, a good many cases of appendicitis and as far as I know none died, and none got well. I do not know of one that would not have been better for operation, which ought to have been made at once. I do not see any necessity of differentiating clinically. The only thing to do is to find that you have appendicitis and then operate.

Dr. J. B. MURPHY, in closing the discussion, said: The last comment of Dr. Le Count is very interesting to me, and I wish to mention that in this case I call catarrhal appendicitis there are to be noted a number of necrotic spots; they look like ecchymoses, but they are not. There is an infiltration of the mesentery more marked than I have seen it in suppurative or gangrenous cases. I noted that the ligature cut the entire mesentery. I do not know that I understood Dr. Bouffleur in connection with foreign bodies. There were 4 foreign bodies in 193 cases, that means about 2 per cent. There were 38 per cent. of enlarged, hard, resisting concretions which produced trouble, not the soft material the Doctor speaks of. If he had reference to foreign bodies such as cherry stones, etc., being uncommon in connection with appendicitis, I agree with him, but the fecal stone is important when it is present in 38 per cent. of the cases. The one I show to-night is of an average size, and you can see that a stone as large as this existing in the appendix must produce pressure upon the wall. I was glad to hear Dr. Moyer, a man from the medical side of the profession, announce himself as he did, that we should make a diagnosis of appendicitis and be satisfied with that, not trying to make any further differentiation until we make the operation; then we can clear up the other manifestations, the same as Dr. Le Count does in a post-mortem.

## SOCIETY PROCEEDINGS.

### American Electro-Therapeutic Association.

*Fourth Annual Meeting held in New York Academy of Medicine, New York, Sept. 25, 26, and 27, 1894.*

WILLIAM J. HERDMAN, M.D., President.

(Continued from page 446.)

### DIRECT CURRENT DISTRIBUTION.

This automatic adjustment of the pressure to meet the constant requirements of a multiple system of translators may be somewhat imperfectly indicated by a water analogue.

When the apparatus here shown is at rest, the water stands on the same level  $L^0$  in all the pressure tubes  $E, F, G, H$ , as was the case in Fig. 4. It is assumed that the rotary mechanism of the pump is constructed in four parts or sections fixed upon one shaft, each part revolving in a separate compartment of the inclosing box. One of the compartments is constantly open for the free circulation of the water, but the other three are controlled by gates or valves numbered 1, 2 and 3.

If now the shaft be revolved by its pulley at a constant speed, while the valves in the cross or multiple arc branches containing the three water wheels are closed, a pressure will be developed by the action of the constantly open section of the pump which will raise the water in the higher tubes to the levels  $L^1$  and  $L^2$ , and allow it to fall in the lower tubes to  $L^3$  and  $L^4$ , and this difference of levels between the

higher and the lower tube will represent the pressure available for useful work in the manner explained in connection with Fig. 4. We may also assume that unless the speed be varied, this useful difference of pressure will remain constant while no wheels are operated.

Now let the valve of wheel 1 be open. A flow will take place through its multiple arc branch, and cause a revolution of wheel 1 and also a slow rotation of a turbine wheel indicated in the main supply pipe (through which all the water passes) and by means of a connecting shaft and bevel gearing, the centrifugal governor at the left of the sketch will also be revolved. When sufficient velocity is attained, the governor will raise gate 1, thus admitting additional water, until the amount of flow is sufficient to properly operate wheel 1 in spite of the friction of the current in the pump and pipes, this friction being compensated for by calling into action the first additional section of the rotary pump when gate 1 is opened. In other words, the pressure delivered by the pump at the cross branch which contains wheel 1 (which pressure was sufficient to properly operate one or more water wheels before any of them were set in motion) is by the flow of current which occurs when that wheel is started, maintained at the proper standard, and this operation of maintaining the proper pressure is brought about by the stimulation or reinforcement of the action of the pump which results from the current flow.

The starting of wheel 2 affords a second path for the propulsion of water through the closed system of pipes, and the greater volume of flow through the turbine wheel increases the rapidity of revolution of the governor and raises still farther the vertical spindle which it controls, until gate 2 is opened and a second additional section of the rotary pump is utilized. A further similarly increased action may be assumed to take place when gate 3 is opened. When any one of the three gates is closed as a result of stopping the revolution of one of the wheels and thus retarding the flow through the main or turbine wheel, a reverse action takes place, the volume is automatically diminished, and the pressure which would tend, in the absence of the regulating mechanism, to increase, and thus make the remaining wheels run faster, is maintained constant, and hence the action of the remaining wheels is unaffected.

A combination of the series and multiple arc ideas was suggested by Mr. Charles F. Brush, very early in the progress of electric lighting. The practical application of his idea is roughly illustrated in Fig. 10. Here a group of translators arranged in multiple arc is placed in each building or area and the different groups are connected in series. By this means the enormous mass of copper required for successful multiple arc distribution is greatly reduced, because a small current may be divided among a few lamps constituting one group, and transmitted through many groups successively over a small wire. While securing this desirable result of a reduction in the cost of conductors, this system is open to the danger which always attends a series circuit having many translators and therefore requiring very high voltage, and it is also defective in that the extinguishing of any translator increases the current through the others of its own group and tends to decrease the current through all the other groups. The practical difficulties which resulted from these conditions were so serious as to be prohibitory, and this method has never been extensively used in electrical distribution.

The difficulties which were inherent in such a multiple series system as that proposed by Mr. Brush were practically obviated for the purpose of large cities as well as of areas of more moderate size, by an invention of Mr. Edison known as the "three wire system." This method was in fact brought out simultaneously with Edison's publication in this country by Dr. John Hopkinson of England, and each of these inventors patented it in his own country. It allowed of avoiding the difficulties of the multiple arc system in a large investment for conductors, and the difficulties of the series system in the matter of independent control of each of the translators, or as I have said, it so far mitigated these difficulties as to make it practically feasible to spread incandescent lamps or motors of moderate size over a considerable area and enable them to supply numbers of scattered consumers, while each translator might be operated without affecting any other.

In Fig. 11 I have shown how this system is practically applied in lighting, for example, large areas of New York City. The two dynamos at the left of the sketch are connected in series; lamps in multiple arc are connected in groups between the positive or red conductor and the compensating middle conductor and also between the middle conductor

and the blue or negative conductor. The system, as a whole, may thus be said to be divided into two multiple arc sections or divisions, one on the positive and the other on the negative side of the middle wire, and these divisions are in series with each other, the larger portion of the current passing out on the positive, through the two groups successively and returning by the negative. While the system is balanced, that is while an equal number of lamps is operated in multiple arc in each of the two groups in series, the middle conductor by which these two groups are connected serves simply to carry the current from one subdivision of the positive section to one or more subdivisions of the negative section, and so simply has an "intergroup" function.

But as one of the objects of the invention is to allow of the individual control of every lamp, without affecting any other lamp, we find that when one of the positive multiple arc subdivisions is turned out, the dynamo on that side will send less current to the system, while the dynamo on the other side supplying the negative division will continue to send the same current as before, but the fraction of its current which is not needed by the remaining lamps on the positive side will pass up the middle wire and join near the lamps the current which has passed through the remaining positive lamps, forming with them a volume sufficient for the negative side. If, on the contrary, a reduction were made on the negative side, the current produced by the negative dynamo would be lessened and the excess of current on the positive side which was not needed on the negative would flow from the lamps toward the dynamo, through the middle conductor, thus making this middle conductor perform a compensating function between the two multiple arc groups which are operated in series.

By such a system as this thirty lamps, for example, may be operated by one-half the current which would be required if they were connected in simple multiple arc, and as a consequence of this reduction of current, the outgoing and return conductors may each be made one-half the size that would be required in the simple parallel system. In addition to this, inasmuch as this one-half the current is projected through the conductors with twice the pressure that would be exerted in a simple multiple arc system, the use of this double pressure allows of the further reduction of one-half in the size of the positive and negative conductors. In short, if the two outside conductors are each made one-quarter as large as before, they will perform their work as economically as before when connected in the manner shown in Fig. 11. The addition of the middle conductor (if of the same size as those on the outside), raises the expenditure of copper to three-eighths of that required in the simple parallel system.

A careful inspection of this figure, in connection with the numbers placed along the conductors indicating that current for so many lamps is flowing at the particular point at which the numbers are located, will show that the middle wire carries but small currents for any distance; that these small currents are in some parts of the system in one direction, in other parts in the opposite direction, and that in some sections of the middle conductor there is no current at all. This state of things exemplifies the normal functions of the compensating wire of the three-wire method, and it is because of this practical perfection of compensation that all the devices are independently controllable. It is usually considered necessary to provide each of the dynamos of such a system with means of independent regulation, so that if the circuit becomes materially unbalanced, the dynamos can be properly adjusted with relation to each other so that each will generate the total E. M. F. necessary to do its work successfully. In practice, however, where more than a half dozen lamps are to be placed upon one service, that is to say in one building or area, a branch from each of the three wires is introduced into the building and the translators are so connected as to place an equal number on each side of the middle wire. Thus a very close approximation to a local balance is maintained throughout the system, and departures from a close total balance are comparatively rare.

The incandescent lamps ordinarily operated on a system of this kind are made to work with 110 to 120 volts, according to circumstances. If such lamps could be successfully made for 220 to 240 volts and of the same candle power as at present, they might be connected across the outside wires of the three wire system, inasmuch as each of the three wire dynamos delivers a voltage equal to that required by lamps of the present type. With such high volt lamps a system could be operated with all the economy of the present three wire system as to cost of copper and drop in the

conductors, and the middle wire might be omitted. Or, if such lamps were to be built for general use (and they have been constructed in limited numbers) they might be connected with a three wire system as the 110 volt lamps are now connected, and the standard of voltage of each of the dynamos, and consequently of the system as a whole, might be doubled, thus providing for four times the number of lamps now operated within a given area, or for greatly increased length of conductors without exceeding the present percentage of conductor drop.

The practical importance, to the physician, of a correct conception of the operation of this law of the distribution of electrical potential along one or many parallel circuits, in proportion to the resistance encountered, receives clear illustration in the extreme case of applying currents fatal to human life in electrical executions. I have witnessed two such applications, and as a result of the first one, I had the pleasure of participating in the discussion of the able paper read by Dr. Carlos F. MacDonald before the New York Academy of Medicine, March 16, 1892. In this paper Dr. MacDonald summarized the phenomena which he had observed at the first seven executions under the present New York law. In response to his invitation, I analyzed the electrical conditions which I observed at the death of McElvaine, the Brooklyn murderer, for the purpose of pointing out the fact that a much greater electrical energy was applied than was apparently necessary to effect the result, because owing to the plan pursued in applying the electrodes, the greatest portion of the resistance encountered by the current was probably not in the vital organs, but in and near the surface contacts and the bony structure. As a result of this assumption (and I think it is susceptible of proof) the greatest fall of potential and therefore the greatest expenditure of joules of energy must take place outside of the brain and other nerve centers, and must fail to have any appreciable effect upon them and upon the heart and lungs, where complete paralysis is in such a case desired.

Perhaps I may be pardoned if because of my very limited opportunities for observing cases which seem to carry the most force to the physician's mind, I use this somewhat repugnant illustration, and reproduce a diagram made in connection with the discussion I have mentioned, and quote one or two of the points then emphasized.

In opening the discussion, our esteemed Fellow, Dr. W. J. Morton, remarked that it was not the mere voltage that must be relied upon to kill, and it seemed to me then as it does now, that from this text a practical sermon might well be preached by some medical authority, applying the principle to the remedial uses of electrical energy in your everyday practice. I may be able to so state the conditions that some one will thus draw the proper practical deductions.

Perhaps a desirable form of expression is that the lethal or remedial effects which attend the flow of a given current, at a given density in any tissue, for a given time, are proportionate to the distribution of fall of potential or expenditure of the total applied voltage.

I think I may say that the fact that alternating currents were used at the execution of McElvaine does not probably cause the problem to vary in any great degree from the conditions expressed in the diagram now before you. In its details I have for simplicity assumed that no variation is met, and the force of the lesson we may draw is not lessened, though it may be found that new factors are introduced by the substitution of alternating currents of varying periods, for the direct distribution to which I am supposed to restrict myself.

To apply a pressure of 1,000 volts, alternating from 200 to 300 times a second, and maintain that pressure for an appreciable time against the resistance of the human body, from the forehead to either leg below the knee, does not probably greatly increase that resistance at the instant of contact. Or, if it has such an effect, the maintenance of the so-called current reduces the effective resistance so speedily that we get from 1,000 volts, an expenditure of energy at such a rate as snuffs out the life of the criminal more quickly than neural impression can be carried from the point of contact to the seat of sensation in the brain.

The energy that kills is therefore (with a given frequency) the product of three factors: 1, the electrical pressure or electro-motive force that is applied to the surfaces of the body; or, in more accurate technical language, the effective difference of potential (in volts) between the electrodes, shown by the Cardew voltmeter; 2, the rate of expenditure of this potential in each unit of resistance (or impedance) in the body, or the number of volts fall of potential to the ohm

(amperes) shown by the ammeter; 3, the time (seconds) shown by the stop-watch. The volt-amperes (watts) give the rate at which the work of destruction is going on; the volt-ampere-seconds (joules) are the measure of energy expended or heat developed in the body during the time of contact.

There is another condition to which I have barely alluded, namely, the "density" or degree of concentration of the current, and the resulting energy expended through the vital centers. While the path of greatest strength of current—or in other words, greatest expenditure of watts—is usually represented by the shortest route or nearest approach to a straight line between the electrodes, this is an exceedingly general statement and the exceptions will probably be found to be numerous. The correct view is probably that the densest current is usually the most direct, with less and less effect on either side, because with increased distance to be traversed, the resistance is greater.

None of these factors are well settled as yet in their relation to the energy actually required to cause instant and painless death. By "death" I mean, now, not alone cessation of consciousness of a perfectly healthy human being in an interval too brief for thought to measure, and the establishment of conditions which produce gradual and final expenditure of the stored nervous energy of the brain and the subordinate centers of distribution of vital force—such as the pneumogastric nerve and the spinal column—I mean, also, total paralysis of all the vital organs and of the nerve centers by which they are directly or indirectly vitalized, so that when the current is broken there can be no reflex action of the muscles, such as would indicate the presence of residual life energy or a possibility of its resuscitation.

I think none of these factors are settled, because it is not yet known how small a resistance may be found when only those parts of the body which must be paralyzed, and only the surface tissues which most readily lead the current to those parts, are included in the circuit. That the contact surfaces used in practice are excellent (and satisfactory) no intelligent witness of one of the later executions will deny. The peculiar scalding effects of the current at the edges of each of the electrodes nearest to the electrode of opposite polarity, and for some distance along the track most readily followed by the greatest density of the current, has been attributed—erroneously, I think—to the contacts themselves, and to the idea that accidental surface moisture has been followed by the current and heated till dissipated in vapor.

In the diagram Fig. 12 I have tried to indicate graphically that near each electrode the area of comparatively good conducting material (moisture-filled tissues) which lies in the line of least resistance, is limited, and a high degree of current density results, until in its course from one electrode toward the other the current finds an expanded path and can spread itself over a larger area without departing very much from a direct line, or at any rate without encountering largely increased resistance. Within this area of great current density or large expenditure of volts to the unit of cross-section of the connecting tissues, the few blood vessels, nerve channels and moisture ducts oppose so great a resistance to the rush of energy as to occasion a great drop of potential, and thus great heat, and the moisture is quickly raised in temperature to the scalding point. Much of it must have been turned to steam under the epidermis and perhaps in the minute blood vessels, and those portions of the body close to the electrodes are parboiled if a large current is maintained.

A little reflection, even from the standpoint of a layman, suggests that with the exception of the 490 watts or 18,000 joules assumed to be expended in and near the vital organs, this large energy may be regarded as uselessly applied. The correctness of this general view was suggested to me by the intensity of the heat observed at the electrodes and the fact that the temperature which I measured at the knee joint was 120 degrees F. (or higher) for nearly two hours after death. Could the same amperes be expended exclusively at the life centers, it might be found that only a low alternating voltage, perhaps 100 or 200 (with 100 to 200 periods per second) would be ample, and that such a concentration in the centers of nervous activity might allow of the reduction of the time to a fraction of that which has thus far been considered necessary.

The idea of "concentration" or great "density" of current is I think best illustrated by imagining the body to be made up of a number of separate paths or circuits connected in multiple arc. In Fig. 13 I have imagined that the brain and spinal cord form a path of low resistance, (say 25 ohms); that outside of this main channel are two circuits of higher resistance, (say 50 ohms each) representing the heart, lungs

and that part of the circulatory system within the trunk; that farther out are two others, still higher (say 100 ohms each). The same voltage (70 volts) being expended in all these five paths, the sub-divided currents through them vary inversely as their resistances, and the central channel receives two-fifths of the entire energy expended in the group. The joint resistance of all the paths is by this assumption only 10 ohms.

It is interesting to note that within the past year the method of applying the current in these executions has been modified to the extent of keeping up the full voltage for only five or ten seconds, and then reducing it to 200 or 300 volts, sufficient to maintain the sudden rigidity of the muscles and complete the permanent paralysis of the nerves which is brought on by the first powerful shock. As a result, after a contact of something less than a minute's duration, there is a complete collapse, with no reflex muscular manifestations or apparent tendency to resume the normal functions of life, and no objectionable scalding of the surface tissues because the maximum heating energy is applied for so short a time.

I have thus illustrated what would to a non-professional mind seem a matter of great importance, namely the determination of the relative resistance of various parts of the body, with the forms of electrodes adapted to the work of electro-therapy and under the influence of the different currents now used. This would probably give more accurate ideas of the effects produced internally by external application of electrodes of given form and area of contact, and point the proper practice in concentrating or diffusing a given current flow under given physical conditions.

During the discussion of which I have just spoken, Mr. A. E. Kennelly, then consulting electrician at the Edison Laboratory, with whom I attended the execution of McElvaine, made a suggestion which is best expressed in the words of his letter to me:

"I think that a high pressure brought to bear upon a man's body between any two points, finds the resistance initially just what we measure it by the bridge, but that it breaks down at a rate rather difficult to foresee. Also that valuable experimental measurements could be made (as you suggest) of the resistance in different parts of the body, *A B*, in the diagram. (Fig. 14.) A battery or dynamo current (direct or alternating) is applied, of the right and readily-supported strength, at convenient points, (say the extremities *C* and *D*) by means of wet bandages. Sponge-faced electrodes, *F, G*, connected with an electro-meter *E*, are then moved from point to point, various distances apart, and the fall of potential studied. I suspect—without pretending to know—that the resistance of the body and its distribution from point to point mapped out by this method, would be maintained in ratio or relative proportion under fatal pressures, even though the absolute resistance fell everywhere.

"I think that an accurate knowledge of the resistance from point to point of an average human body might assist occasionally in the diagnosis of disease, and the comparison with the resistance of a corpse might have useful results to show."

That eminent scientist and teacher, the late Prof. John Tyndall, has left upon the pages of modern progress a record which every student of the physical sciences should examine with minute care, in an address delivered at the Royal Institution of Great Britain early in 1879; he made the following beautiful expression:

"It was my custom some years ago whenever I needed a new and complicated instrument, to sit down beside its proposed constructor and to talk the matter over with him. The study of the inventor's mind which this habit opened out was always of the highest interest to me. . . . Such minds resemble a liquid on the point of crystallization. Stirred by a hint, crystals of constructive thought immediately shoot through them. . . . They have the penetration to seize the relationship of facts and principles, and the art to reduce them to novel and concrete combinations."

If my fragmentary remarks on this subject of electrical distribution have conveyed a hint to some such mind, the highest object of my paper has been accomplished.

#### DISCUSSION.

DR. J. H. KELLOGG of Battle Creek, Mich.—said he had been especially interested in the last suggestion of the speaker as to the varying resistances of the body being made a means of diagnosis. The same thought had occurred to him four or five years ago, but he had found what seemed to be an insurmountable difficulty—a variation in the thickness of

the skin in different individuals, and the difficulty in so adjusting the electrodes as to have identical conditions. He had concluded that the only accurate method would be to introduce the electrode beneath the skin. Another difficulty which he had met with was the fact that the skin itself presented such a large proportion of the resistance of the entire body that there would be but a very small margin for investigation as to the variations in the different bodies. He would like to have the reader of the paper propose some way of overcoming these difficulties.

MR. JENKS said that his knowledge did not extend beyond the suggestion, in fact this suggestion had been made to him by Mr. Kennelly. He was not aware that any experiments had been made which would throw any further light on this subject.

DR. MORTON said he did not wish such a valuable paper to pass by without saying something in recognition to the author. He did not feel competent in any sense to discuss those intricate electrical problems from the standpoint taken by the author, but there were certain questions which suggested themselves to the minds of physicians. He had been especially interested in the statement that physicians were applying a certain amount of *energy* to the living organism—energy against energy. He was also pleased in the reduction of the expression energy, to terms which we could all understand. If the physician used the Franklinic current his mind was occupied with electro-motive force; if he used the constant current, then current strength was prominent in his mind, etc. We first thought a great step had been made when the milliamperè meter was introduced, but we now know that we should take into consideration also the question of voltage.

It was true that we might express electrocutions in terms of horse-power, and speak of them as two, three or four-horse-power deaths; the author said we must go still further and take in the elements of time and express the effect of the current in joules. This would mean that we must go still further in our practical work and express it also in joules.

This subject of electrocution was a grewsome one, and in his opinion we, as electro-theraputists and physicians had nothing whatever to do with it. We should relieve and cure people and not deliberately take any part in causing the death of any human being. So far, he had always refused to witness these executions, although he had been invited to do so. He believed with Monsieur D'Arsonval, who put forth that startling theory that these criminals were not really killed by electricity. He thought it was even now a question of the old Scotch verdict, "not proven." This being the case, the person performing the autopsy was responsible for the death of the criminal, so the responsibility was again turned upon the medical profession where it did not belong. In order to prove that the death was due to electricity, we should wait for decomposition to occur, and not perform an autopsy within a few minutes after the application of the current.

In conclusion, the speaker said he welcomed such a paper, and particularly the subject of measurement reduced at last to one of energy instead of voltage and current strength.

DR. DICKSON said he agreed with the last speaker that when we stopped at using the milliamperè meter we had not done all we should do.

(To be continued.)

### Louisville Academy of Medicine.

Regular meeting was held March 18, 1895.

DR. I. N. BLOOM was the first speaker, and said: I wish to show this negro woman, about 40 years of age, whom I saw for the first time on February 22, having been sent by Dr. Satterwhite. At that time she exhibited an eroding ulcer, about the size of a penny piece, involving the left ala of the nose, on its outer margin. While I was in some doubt as to the diagnosis, between epithelioma and lues, I noticed her fingers, which present the characteristic signs of hereditary syphilitic dactylitis. The woman, however, says that her fingers have only become so in the last two or three years. She was married about twenty years ago, but has been separated from her husband a number of years. In addition she complained, when she first came under my observation, of severe headaches, not to be located in any one part, more severe at night. Under the mixed treatment these have almost disappeared, and as you can see the ulcer upon the nose is almost entirely healed. I show this case chiefly on account of the dactylitis. These cases are seen with extreme rarity. I was in the hospital in Vienna for years, as Hospitalant, and saw very few cases. In out-patient, hospi-

tal and private patients, I do not think I have seen more than twelve cases. The text-books would lead us to believe that they are common. I have not seen them, and would like to ask if any of the Fellows have seen a similar case. I see typical cases of syphilitic manifestations repeatedly. This case presents no other features of interest.

DR. T. C. EVANS—I happened to be present in Dr. Bloom's office when this patient came in, and noticed the dactylitis. It has the appearance of that seen in congenital syphilis. I have seen five or six cases in children with hereditary syphilis, but this is the first case I have seen of acquired syphilis with dactylitis.

DR. AP MORGAN VANCE—It perhaps happens that the general surgeon sees a good many more of these cases than the specialist, he being consulted for some "bone trouble." I have seen considerably more than a dozen cases, I think, in my fifteen years' experience.

DR. W. C. DUGAN—I wish to show a specimen removed from a case operated on yesterday. It is the omentum and sac removed from a femoral hernia. There is one point I want to bring out in reporting the case: Day before yesterday at 2 o'clock, she complained of pain in the femoral region; her family physician was called in and diagnosed femoral hernia. He used taxis for a few minutes as did the patient also without success. I was sent for and found a large tumor in the groin, no pulsation or coughing, no tympany. Pulse 80, and good. No perspiration. The patient was inclined to joke, in fact, all the symptoms showed there was no great impression of the nervous system. I looked on the case rather as an omental hernia than an intestinal; and was inclined to let it go until morning, but fearing there might be a small piece of gut, I operated that night. Dr. Evans administered the anesthetic. An incision was made through the abdominal wall, not cutting in through Gimbernat's ligament as usually advised, but Poupart's ligament, cutting through the sac, and made a radical cure. Here was a case with a pulse under 80, no constitutional distress, had vomited only a few times, yet the gut was almost gangrenous. This shows that we can not tell what we are to find. If I had let her go until morning, gangrene would have occurred. She is doing well now and will soon be up.

DR. VANCE—I think Dr. Dugan was right in not letting an incarcerated hernia go from night until morning. It is right to give the patient the benefit of the doubt.

The paper of the evening was read by Dr. John F. BARBOUR. Subject,

### THE PRESENT STATUS OF LINEAR CRANIECTOMY.

The author stated that the first case operated upon was by Dr. Fuller of Montreal, in 1878, for idiocy, and that the operation was not done again until 1890, when Lannelongue performed it. The latter's statistics were quoted. These were written four years ago, but since he has been silent. All reports lack as to the state of the patient before operation. Its object is to give full scope to the brain by lessening resistance, there being premature ossification. The following pathologic conditions were mentioned as causing idiocy:

1. Microcephalus.
2. Hydrocephalus.
3. Arrested development of the convolutions.
4. Poroncephaly from congenital malformations.
5. Pseudocysts from pathologic malformations.
6. Hypertrophic sclerosis.
7. Atrophic sclerosis.
8. Tumors of the brain.
9. Meningitis chronic meningo-encephalitis.
10. From pachydermatous or myxœdematous cachexia due to absence of thyroid gland.

Eighty-nine operations were tabulated. There were sixteen deaths; the results were practically *nil*, in twenty cases; of the remaining fifty-three, four recovered from the operation, one had epileptiform attacks less frequently, and in forty-eight there was improvement but the details were meager and unsatisfactory. There is hardly an operator who has submitted a later report. The history of the case reported, which occurred in the writer's practice, was as follows:

There was no history of syphilis, idiocy or insanity in the family. At four months the anterior fontanelle closed, and the symptoms dated from this time. There was no sphincteric control; the child could not sit alone erect, it had a pained expression, low whimpering, epileptiform seizures as many as twenty-four times in a day. She was extremely restless, recognizing only her milk bottle. The operations were done by Dr. Vance—linear craniectomy April 6 and

June 16, 1893. The immediate effect was remarkable. Three hours after, when spoken to she noticed, and followed a bright toy with her eyes; had an intelligent look, and the pained expression was gone. The subsequent history is that the child is in even worse condition than previously, but the epileptiform attacks are less frequent.

His conclusions were as follows:

1. Premature synostosis of the cranium does not occur in idiocy.
2. The arrested growth of the skull is due to the arrested development of the brain and not *vice versa*.
3. The lesions to which idiocy is due are profound, varied, extensive and by no means susceptible of relief by craniectomy.
4. The results obtained by operation are slight, doubtful, or nil. So that over against this operation we must write in letters of fire: "*Mene, mene, tekel upharsin.*"

#### DISCUSSION.

DR. VANCE—I have operated twice for microcephalus by linear craniectomy. The first patient was 9 years of age, and died seven hours after the operation from an accident. I take it, caused by boiling water being used in the irrigation. The second case described by Dr. Barbour is not improved. I saw the case a short time ago, two years now since the operation, and it is the subject of inanition, the mother never having been able to get it to take anything but the bottle. I agree with the essayist perfectly that craniectomy should be obsolete, especially in the light of the causes of idiocy. The operation in itself is not very dangerous. I think it possible that the instruments used take too narrow bites and the bone perhaps can ossify, as shown by one of the illustrations exhibited by Dr. Barbour. This is especially the case with the one devised by Keen, of Philadelphia; the one devised by Hopkins is wider. I will not do the operation again.

DR. W. C. DUGAN—There is only one logical conclusion in regard to this operation, and that is that it should not be done. I have operated twice; that is, have examined the brain of idiotic children post-mortem. One was a boy 16 years old, who died at the asylum from an attack of malignant dysentery. In taking off the scalp it was noticed how short was the bi-temporal diameter. As soon as the calvarium was detached the intracranial pressure was shown, and afterward the skull top could not be pushed down. The connective tissue predominated and explained the size.

At a meeting of the Kansas State Medical Society in 1885, a child was shown, and I noticed this same condition, a short bi-temporal diameter, and advocated the operation of multiple trephining to allow expansion, not knowing it had been previously done. I think that the premature ossification is due to lack of brain development rather than the opposite.

DR. WM. BAILEY—I think the pathologic conditions are in doubt as to the cause of this premature ossification. In the case which Dr. Dugan reported, where did the extracranial pressure come from if this were not a case of early bony development? I agree with the conclusions offered by the essayist. I consider of the eighty-six cases reported, the sixteen which died were the most successful.

DR. BARBOUR—I suppose that in the course of time, when we become more civilized, we will give those who are so congenitally undeveloped as to be hopeless, the benefit of euthanasia. It is a significant fact that no second report is made by any of these operators. The primary effects of the operation are remarkable, and many of the brilliant reports are due to this temporary effect. I can not understand why they are produced. I think the bottom has fallen out of the operation thoroughly.

DR. W. C. DUGAN—I have a case under my observation which is causing me no little anxiety, and I wish to report it, hoping that some Fellow of the Academy can help me out: The patient is a member of a prominent family. She has been a nervous character all her life, and there is a nervous element in the family. She has been in the hands of various surgeons and physicians. The question in my mind is, Should the menopause be brought on? At the time of the menstrual periods she is worse, but during the month she is more or less nervous. She is not satisfied with anything and wants to run away. She complains of pain in the womb and left side—on examination nothing marked could be found; slight tenderness on the left side; the right ovary only could be felt. Are we justified in bringing on the menopause? To-night she is very nervous, though it is the middle of the interval between periods. She has these spells of what might be called hystero-epilepsy and remains in them for a number of hours. She eats but little, but is

fairly well nourished. She is about 26 years of age and married, has conceived three times but aborted at two or three months. She wants the operation done.

DR. F. C. WILSON—It seems to me that the operation of ovariectomy in this case would be justifiable. As far as child-bearing is concerned, the prospects are it is unlikely, if she conceived, that she would go to full period of gestation.

DR. VANCE—It seems to me possible that the malposition of the left ovary might explain the nervous phenomena. I would certainly make an exploratory incision, and if the ovaries were healthy would leave them.

DR. FRANK—The subject is very interesting and important, and a difficult question to decide. I believe that an exploratory operation is justified, and if it is found that one or both ovaries are diseased they should be removed. I do not think one is justified in removing appendages which are perfectly normal. I believe that the consensus of opinion is that the ovaries have nothing to do with such attacks and few patients are benefited by operation.

One year ago I had under my care a patient who had hystero-epileptic seizures at menstrual periods, and there was always great ovarian tenderness. She was 19 years of age, menstruated first at 14, and married one and one-half years later. I operated and found the ovaries apparently normal, and contrary to my better judgment, the patient having previously begged that something be done for her relief, I removed both ovaries and tubes. On section the ovaries showed numerous cysts not Graafian follicles, but destroyed ovarian structure. The tunica albuginea was very dense over the ovaries. This case is similar to Dr. Dugan's. I do not believe one is justified in removing ovaries if no pathologic lesion is seen. Seven or eight months after the operation on this patient was done she was having no attacks and was well.

DR. WATHEN—I am sorry I did not hear the report of the case that I might speak of the subject more intelligently. I have done the operation a good many times for great nervousness, removing ovaries that were not enlarged but partly or entirely cirrhotic. In these fortunately I have had almost universally good results; all were practically restored to health; several had been invalids for years, one for thirteen years, and all could walk about within a few weeks. Those cases of hystero-epilepsy have not done well; all recovered from the operation and apparently for awhile were better, but they usually recurred. One case was very much benefited, but the tube was found filled with pus, and this probably had been the cause of the trouble. It has been the experience of abdominal surgeons who have operated on a great number of these cases that the results have not been satisfactory. In the operation done for hystero-epilepsy when there are not well marked lesions, unless it is plainly shown that the sieges are due to the ovaries, and so far as we can judge caused by ovulation and menstruation, we should remove the uterus with the ovaries and tubes. If done through the vagina nothing is added to the mortality and there is no abdominal wound left for a hernia to develop.

In conclusion, I would say that I am opposed to the removal of the tubes and ovaries for the relief of hystero-epilepsy unless we are convinced that ovulation and menstruation are the cause of the trouble.

DR. DUGAN—I have operated on two cases for hystero-epilepsy and both are well. One, Miss F. H., aged 22, had been an invalid for many years. She had epileptiform convulsions at her periods with melancholia in the interval. She was emaciated and had been bed ridden most of the time for two years. She was operated on at St. Joseph's Infirmary, under chloroform. She had great trouble from vomiting for four or five days, but afterward nothing but hot flushes for eighteen months. The ovaries were cirrhotic, like cartilage, hard and fibrous. When operated on she weighed 100 pounds; she was perfectly well a short time ago when I saw her, weighed 180 pounds and said she did not know what it was to be sick. With such an experience I am inclined to go back and practice what others have discarded.

DR. FRANK—Two weeks ago I saw a case in consultation, and made the diagnosis of appendicitis, but advised waiting for urgent symptoms. The patient was up and out of bed, bowels alternating constipation and diarrhea. There was pain in the right iliac region and a marked tumor on the right side pointing in the direction of the axillary line; it was hard, painful and fluctuating. There was no doubt as to the diagnosis. The remarkable thing is that the man has been up and about, has a temperature, pulse 102, chills irregularly, and perspiration every two or three days. I will operate tomorrow.

CHORUS—"Operate to-night!"

## SELECTIONS.

**Cow's Milk, its Sterilization and the Nourishment of Children.**—

The article under this heading in the *Berliner klin. Wochenschrift* by Biedert is chiefly polemical and directed against Heubner. It contains no new facts of importance, but its essential drift is to show that in the depreciation of the fitness of milk as food for children, the chemic composition of the same from the bacteriologic standpoint must be regarded of prime importance. The superiority of mother's milk to cow's milk in this connection must never be forgotten. In conclusion, the writer calls special attention to the advantages of his cream mixture and its increasing recognition. —*Centralblatt für innere Medizin.*

**Two Cases of La Grippe of Pseudo-phthisical Form.**—(Chatin

and Collet in *Lyon Med.*, 1894, No. 41.) These writers observed two cases of influenza with pulmonary complications which they were forced to regard as phthisis from the physical examination. There existed dullness on percussion over the apices, sonorous râles, cavernous respiratory murmur, copious, purulent, nummular sputa. In one case the diagnosis of phthisis was given up, because there was no fever and no loss of weight and especially because no tubercle bacilli were found in the sputum. The other case proved fatal, and the autopsy showed edema of the lungs, splenization at the apices, no sign of tuberculosis, no broncho-pneumonia, no caseous foci. Similar observations have been made previously. —*Centralblatt für innere Medizin.*

**The Influence of Erysipelas on the Course and Termination of Asiatic Cholera.**—N. Blagowjeschtschenski (*Medicinskoje Obosrenje*, 1854, No. 15), during the cholera epidemic superintended the bacteriologico-clinical station opened in Merv

(in the trans-Caspian province), and observed here, among 300 cases of cholera in hospital, with a mortality of 52 per cent., the coincidence of this disease with erysipelas four times. In these cases, in all of which the diagnosis was confirmed bacteriologically, the erysipelas was first manifested during the algid stage on the third or fourth day of the disease. In every case the appearance of the eruption influenced favorably the course of the cholera. The low temperature yielded at once to the high temperature curve of erysipelas. Diarrhea and cramps ceased immediately and the general condition of the patient became markedly improved within twenty-four hours. The languor disappeared, urine was excreted, appetite and sleep returned. The course of the erysipelas was also relatively light and the eruption not extensive. In conclusion, he writes: "If one can assume that, under the influence of the toxin producing cholera, the heat center in the organism is paralyzed, in the same way it can be accepted that this center under the influence of the erysipelas toxin regains its irritability." —*Centralblatt für innere Medizin.*

**Retention of Water in Fever.**—Contribution to the Question

of the Importance of Ingestion of Water and Increase of Elimination in Infectious Diseases.—(Julius Glax at the celebration on the completion of the thirtieth year of the Professorship of A. Rollett). The writer formulates an opinion, based on fifty-three cases of typhus (abdominalis) on the question often answered contradictorily, whether the human body retains water in the tissues during fever, or on the contrary is deficient in water. The urine was collected and no case included in which diarrhea was too free. Treatment, cool bathing and galvanization at the neck. Amount of water ingested was noted. He concludes that there is a conservation of the water supply during fever, and in convalescence an increased elimination, frequently coincident with the decline of temperature and at times an indicator of speedy complete defervescence. On the other hand after the initial chill and subsequent rise of temperature, the elimination is usually increased for a short time. The explanation is that at the onset of fever, while the blood pressure is yet high, the diuresis occurs, but a diminution ensues as the pressure becomes lower and a still later increase as strength returns. If strength is not much impaired, the

elimination is only correspondingly decreased. An increase in ingestion of fluids increases the elimination in most cases only after defervescence has begun, while during the height of the fever, diuresis appears to be more favorable, the more limited the ingestion. The recommendation of Cantani and Sahli, that infectious diseases be treated by increased supply of fluids to cleanse the tissues is combated at some length as founded on false premises. In conclusion, the assertions of the writer are easily reconciled with the fact that by drinking cold water in health the temperature and pulse are lowered, and diuresis occurs, for this happens only when the heart and blood pressure are normal. —*Centralblatt für innere Medizin.*

**Influenza and Accompanying Pneumonia During the Last Epidemic, 1893-94.**—Gineiner (*Prager med. Wochenschrift*) had the

opportunity to observe 403 cases of influenza in Donawitz by Leoben between Dec. 10, 1893, and March 11, 1894; 6.9 per cent. of all the inhabitants were attacked, three times as many adults as children, and three times as many men as women; 27 per cent. of the cases occurred between the ages of 30 and 40, and no child under 1 year was included. The largest number lived on the ground floor (50.1 per cent.), while the third story held the fewest (5.5 per cent.). The most commonly observed group of symptoms was: sudden chill or chilliness with a temperature of 39 to 40 degrees C., aching, feeling as if one had been beaten, heaviness of the head, anorexia and constipation. These symptoms lasted on an average two or three days. It was never possible to recognize signs in the lungs in the first days; these, beginning later, belong rather to the complications. The nervous system was very seldom affected, but neuralgia was often seen as a sequela. Protracted dyspepsia was a frequent complication, and quite often enlargement of the spleen. Acute nephritis in 1 per cent. of cases. Ninety cases of influenza, also 22.3 per cent. of all forms of sickness, were complicated with pneumonia, and of these 64.4 per cent. were in men, 14.4 per cent. in women, and 21.2 per cent. in children (none below 10 years of age). Almost all the children were attacked with pneumonia as a complication, but those patients between 30 and 40 years of age were best able to withstand the severe attacks. The greatest percentage of cases complicated by pneumonia (56.6 per cent.) and also the greatest mortality (27.4 per cent.) occurred among those living on the ground floor. The influenza pneumonia was distinguished from croupous pneumonia by the heavy sweats which were present from the onset, but which did not influence the temperature. The type of fever was also different. The decline was more commonly by lysis than by crisis. Meningitis complicated ten pneumonias (11 per cent.) on the fifth to the eighth day, always with fatal termination, while Jürgensen states 5 per cent. as the ratio of meningitis in croupous pneumonia. While in croupous pneumonia generally after complete consolidation the condition remains stationary until the temperature falls, in influenza pneumonia the condition was always changing, one area beginning to clear, while another previously free, suddenly became infiltrated. The sputum was generally rusty. The mortality in influenza pneumonia amounted to 27 per cent., and was largest among the elderly patients; no child died. It is interesting to note, that during the influenza epidemic, no other infectious diseases prevailed except a few cases of typhus (abdominalis). Sickness increased with the lowering of air pressure and temperature; cloudy weather increased the disposition, but no influence could be ascribed to a precipitation of moisture. The direction of the wind, on the other hand, seemed not without influence, for in a valley lying south of Donawitz, which had hitherto been exempt, suddenly in the early part of February the residents of various houses were attacked, and records show that from the end of January the wind was constantly from the north. Surely the wind bore onward the specific cause, since a direct transfer by means of the existing active intercourse would have been accomplished much earlier.

The greater disposition to the sickness among those living on the ground floor, which is also the case, according to Buchmüller, in croupous pneumonia, and also the firm hold of influenza on certain houses, led the writer to the conclusion that the cause is developed in the earth, and thence reaches the dwellings. Since he was never able to find a direct transfer from person to person, he regards influenza as a miasmatic infectious disease. The chief complication, pneumonia, might also be induced by the same influence. —*Centralblatt für innere Medizin.*

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:  
PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MARCH 30, 1895.

THE BOARDING OUT SYSTEM FOR THE CHRONIC INSANE.

The January issue of the *American Journal of Insanity* contains an interesting article on the Scotch system of caring for the insane in private houses, a system that while not peculiar to Scotland, has probably there reached its best development. The observations therefore of a competent observer like Dr. Riggs, the author of the article, have a decided value as showing the success or otherwise of the plan, as it appeared to him under the most favorable conditions. The noted colony of Gheel which has been often described, with praise or condemnation according to the predilections of the observer, is probably no better, if indeed it is not much worse, in its management than the Scotch system of guardians under the constant and direct supervision of the Lunacy Board.

Dr. Riggs' conclusions are, on the whole, very favorable to the system as he saw it, and yet he does not feel ready to recommend it for adoption in this country under our present conditions. It is doubtful whether we can find here any communities like those of Gheel, Balcurvie or Kennoway, or if we could, it would be our best resource for the care of any large proportion of the chronic insane. There we find communities that have grown up with the care of the insane as their chief means of support, and which would probably cease to exist as communities without this. This in itself, indicates a state of affairs which we ought not to be anxious to bring about, though with the increase of density of population, and the consequent greatly augmented difficulties of making a livelihood, we may yet come to it in some parts of our country. In Scotland these aggregations, it must be said, are not favored by the

Lunacy Commissioners who prefer to see the insane a less predominating portion of the population than is the case in Gheel and some other localities.

Dr. Riggs shows further in his very clear *exposé* of the system and its method in Scotland, that in its inception it was only an obligated alternative to overcrowding asylums or multiplying them beyond the capacity or willingness of the taxpayers, and its success has been rather greater than was at first expected. Indeed, the Scotch commissioners and superintendents are mostly partisans of the system at the present time. That it has some disadvantages, however, can be readily seen from his account. The presence of the insane does not make the communities attractive to outsiders, and even with the almost ideal supervision of the Scotch Board of Commissioners he observed some defects of management that were undesirable and, had he had a chance to make more than a mere casual inspection, it is probable he would have seen many more. In a well managed asylum it is impossible but that some undesirable things should occasionally occur, and even with the best selected demented, the chances for their occurrence are almost infinitely multiplied in the necessarily laxer discipline of the boarding out system. It relieves asylums and it is therefore naturally to be expected that it should find favor with superintendents and as it is the creation, so to speak, of the Scotch Lunacy Commissioners and their success with it has been so great, it is not at all remarkable that they should see it in the most favorable light. It is probable, moreover, that, as already remarked, the system is at its best in Scotland. That it is not so faultless in other countries is shown by an article in the January number of the *Journal of Mental Science* by Dr. JOHN SIBBALD, one of the Scotch Commissioners in Lunacy, on "The Lunacy Administration in Berlin and Scotland with Special Reference to the Care of the Insane in Private Dwellings." This article is as yet incompletely published, and it would therefore be unfair to assume what are Dr. SIBBALD's conclusions, but he found that in eight years, out of an average number of apparently not over four hundred insane thus cared for, there had been three suicides, two accidental deaths and four cases of pregnancy,—the minor accidents, except one case of loss of an eye—not being reported. This would be a formidable record for an asylum of that size and is not a recommendation for any system.

One objection to the system, that is not mentioned by Dr. Riggs or others, but which seems a very important one, is that of the influence of the presence of the insane in families and communities. There is a certain contagion in insanity, not necessarily a microbic one, but rather a mental infection that has often a very extensive and serious influence. In an established community like Gheel, or one or two

Scotch villages where the residents are, we may say, acclimated and have become hereditary attendants to the insane this danger is perhaps at a minimum, but the scattering of the chronic insane throughout a farming section, for example, with the freedom and daily contact with individuals of all ages, susceptibilities and predispositions, has a very objectionable aspect in this special regard. There is a certain element of risk in it, not only to the intellects but also to the morals of those who from age or otherwise are in any way impressionable in these respects, and even the best selection of subjects can not altogether guard against this danger. It may not be a very apparent objection to the system, but it is a real one that ought not to be left altogether unconsidered.

Thus far the boarding out plan has been experimented with only to a very slight extent in this country, and in only one State, Massachusetts. It is, however, one of the plans frequently and ardently advocated, and will probably before long come to the fore in some form or other, in many other sections. It falls in with the sentimental tendency to demanding all possible freedom and lack of restraint for the insane, which seems to be growing rather than decreasing, but which has its bad as well as its good side, and should be tempered by good judgment with careful appreciation of all the actual conditions. It is safe to say that if adopted anywhere, it should only be considered as an experiment and an enforced alternative; not as really an improvement over other methods of public care. We certainly can not, in the existing state of affairs in many portions of the country, immediately expect any such success as has been attained in Scotland, where the best we can say is that the disadvantages are reduced probably to a minimum. Well managed county almshouses, such as are found in different parts of the country,—the so-called county asylums of Wisconsin, for example, with all their disadvantages, and they are often very serious ones, are, on the whole, probably a better method of caring for the overflow of the insane from the asylums in this country than would be the plan here discussed. At least this will be true until we can have systems of State care for all the insane, with supervision as competent and thorough and independent of political changes and control as that of Scotland.

#### "PRINT THE FORMULA ON THE LABEL."

The *New York Ledger* has had the name of being a safe family newspaper, and not a few medical men throughout the country have been among its regular patrons. In view of this fact it should be noted that that paper has, in its editorial columns, come out boldly in the defense of quack remedies, and has already opened its columns to the manufacturers of sarsaparillas, etc. The editor takes for his text the fact

that that grand old State, Alabama, has before its Legislature a bill that requires that no patent or proprietary medicine shall be sold unless the formula of the compound shall be printed on the label of the package containing the article.

The editor finds cause for blame against the conservative and preservative legislators of Alabama on the score that such bills are the outcome of the trades-unionism and selfishness of the medical profession. He alleges, while he can not prove, that the free use of quack medicines make a saving in the doctors' bills; giving little heed to the well-known fact that much of the money spent for patent compounds is money spent in the behalf of a speedier call for the physician or the undertaker than if the compounds were left alone. The editor unadvisedly maintains that quack remedies do enable our fellow-citizens to dispense with the services of the regular practitioner, and that this is the real incentive to legislation of that restrictive character that has been found most salutary in certain foreign communities.

The fact remains that the course taken by our Alabama fraternity is probably the one that cuts most deeply into the patent medicine business; therefore, let us urge on every suitable occasion that the manufacturers of these more or less dangerous articles be forced to *print the formula on the label*.

The following are two of the closing paragraphs in the *Ledger* editorial named above, going to show, first, that the quack medicine is convenient and therefore worthy of financial recompense; and second, that a little knowledge of medicine is not a dangerous thing. Nothing in the way of refutation of these arguments needs to be adduced before the readers of this JOURNAL, but we believe it to be well for our readers to know a little of the kinds of defenses that are being constructed for dangerous quack preparations:

"The firm that put on the market the gimlet-pointed screw and amassed a fortune by the means of it had, by reason of the low price and convenient shape in which this article was furnished, a claim on the public for suitable recompense for their efforts. Just so the individual who prepares and offers for sale in convenient form some simple medicine has every right to the monetary return that an excellent article is sure to bring.

"It is the sheerest nonsense to suppose that medical men can form a close corporation and absolutely control the dispensing of medicines. The world is full of people who have most excellent sense about the use of remedies, and are quite as capable of prescribing them as the ordinary doctor. Of course, this cuts into the business of the physician in a very emphatic fashion, and this fact, and not the affectionate solicitude of legislators, is the motive that underlies the introduction of bills of the sort described."

**The Forty-sixth Annual Session** of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

### TELEPHONE RATES' BILL IN THE NEW YORK LEGISLATURE.

The physicians of New York, to whom the use of the telephone has grown to the height of a necessity, have exhibited unwonted interest in this year's campaign against existing extortionate rates. The bill against the companies, as originally introduced, fixed the rates at \$78 and \$66 respectively. These rates have since been increased to \$125 and \$85 respectively. Moreover, a six months' continuance of the old high rates is permitted, and the companies can not be bound to follow the new schedule if they can show that they are not remunerative.

The companies are very powerful at Albany and have been able, year after year, to thwart the efforts of physicians and others to lower the tariff. Medical men in other States, besides New York, will be interested to follow the progress of this fight with this grasping monopoly.

### THE QUACKS ARE NOT SUPPRESSED.

It is quite as well to know that the advertising quack flourishes just as luxuriantly as of yore, notwithstanding boasts that are being made. He has never been entirely suppressed in our large cities, and at this time the daily newspapers give abundant evidence of the fact. Moreover, we are credibly informed that itinerants are still making periodical trips, and that even in the State where the anti-itinerant movement was so successfully carried out by the late DR. RAUCH they are still active. Boards of Health, in pursuit of other attractions, sometimes grow somnolent.

### THE JOURNAL TRAIN.

The itinerary of the JOURNAL train from Chicago to Baltimore has been issued. The Pennsylvania Railroad has done its utmost to provide the very best service known to modern travel, and all the world knows that when the Pennsylvania Railroad tries to do anything, that it is always done well. Our members from the Pacific coast, the interior valley and the great Northwest will meet many of their brethren and travel in luxurious fashion, by taking the JOURNAL SPECIAL THROUGH PULLMAN VESTIBULED TRAIN, from Chicago to Baltimore, Sunday, May 5, at 3:15 P.M. For space, address H. R. DERING, Ass't Gen'l Pass'r Ag't, 248 S. Clark Street, Chicago, or TRUAX, GREENE & Co., 75-77 Wabash Avenue, Chicago. The rates of fare will be one and one-third, making \$23.20 for the round trip and \$5 for sleeping car each way.

The JOURNAL train may be joined at the principal points between Chicago and Pittsburg, by notifying MR. DERING in advance, by letter or telegram.

### THE EXHIBITS AT THE MEETING.

As will be seen by the illustrations, the intending exhibitors will have finer accommodations than at

any previous meeting, and the arrangements for the exhibition of their wares leave but little to be desired. The Cyclorama Building has its main entrance directly opposite that of the Academy of Music, and every attending member will have little excuse and no reason for non-attendance on the large exhibit hall, where in these latter days, it has come to resemble a great fair where everything relating to medical pharmacy, optics, instruments, educational appliances, medical literature, sanitary goods and dietetic articles are shown by practiced hands. A good deal may be learned at the Hall of Exhibits, and the wise member will use his opportunity to good advantage, who devotes a reasonable proportion of his time to this feature of the annual gathering.

### THE FAULT OF THE CONTRACTOR.

We regret extremely the delay that has occurred in the mailing of the JOURNAL to our readers for the past two weeks.

When we leased the premises No. 86 Fifth Avenue, it was included in the contract that power to run our machinery should be furnished by the lessors, MESSRS. HARRISON BROTHERS, then the owners of the *Times*. When they sold the *Times* property to MESSRS. KRAUS and HAWLEY, they transferred the lease to that firm.

In a few weeks that firm ceased to exist; the *Times* newspaper gave up the ghost and was merged into the *Times-Herald*, the *Times* composing room and property being transferred to the *Herald* Building. Since that transfer the difficulties of managing the JOURNAL have been manifold, and by the breaking of a shaft, for three days last week our presses and other machinery were silent, and only by the hardest labor on the part of our employees were we able to issue the JOURNAL at all, and as this week commenced with another failure and breakdown of the power, we felt obliged to put the case before our readers so that the real cause of the delay in the issue of the JOURNAL may be placed on the shoulders where it belongs. We are, however, promised by the lessors, that every precaution to prevent accidents to the machinery will hereafter be taken.

The JOURNAL will be from time to time subject to such unavoidable annoyance until the ASSOCIATION owns its own building.

## CORRESPONDENCE.

### Retinal Images in Oblique Astigmatism.

CHICAGO, March 24, 1895.

To the Editor:—Dr. Savage's letter in the issue of March 16 reminds me very much of the comment on a book of which the reviewer has read only the title page and imagined the rest. Indeed, Dr. Savage would be a mind reader of extraordinary ability if he could have guessed correctly the full extent of my remarks before the Chicago Ophthalmological Society from the simple sentence of the report, "he proved

by demonstrations that oblique astigmatism does not cause obliquity of the retinal images." Since Dr. Savage did not know anything about my arguments it is not surprising that his criticism is so little to the point and consists simply in "threshing over old straw."

The object of my remarks was to demonstrate the fallacy of the proposition that in oblique astigmatism the retinal images of horizontal or vertical objects are not themselves horizontal or vertical; or in other words, as Dr. Savage formulated it in his paper on the harmonious symmetrical action of the oblique muscles, that the image of a horizontal arrow can not be in the horizontal meridian of the retina, but is made slanting by the prismatic action of the astigmatic cornea." This obliquity by a prismatic action of the astigmatic cornea was *assumed* also (but not *demonstrated* as Dr. Savage erroneously stated) by Dr. Lippincott to explain certain phenomena of distortion of images in astigmatic eyes. Now I have shown and I believe convinced by my demonstrations all the members present at that meeting, that the image of a horizontal (or vertical) line thrown upon a screen through a spherocylinder lens equivalent to an astigmatic cornea does not suffer any such prismatic deflection. As a full account of my arguments will appear in the April number of the *Annals of Ophthalmology and Otology* it is not necessary to argue this point here any further. It is sufficient to repeat what I have already once stated, viz., that inasmuch as Dr. Savage was not conversant with the nature of my arguments, he could not intelligently and successfully attack them.

In conclusion, I wish to call attention to the fact that in this letter Dr. Savage has used the words *obliquity* and *distortion* of the retinal images as if they were interchangeable terms. But they are not synonymous; they apply to radically different conditions; for the retinal image may well be distorted without necessarily being oblique. The image of a luminous point, for instance, is distorted by an astigmatic cornea into an oblong figure, because the rays passing through the astigmatic meridian are not brought to a focus in the retina. The elongation, therefore, always corresponds with the direction of the astigmatic meridian; if the latter is horizontal (or vertical) the oblong image will be horizontal (or vertical) and if the meridian is oblique the elongation will be in an oblique direction; but it is evident that this obliquity of the image is caused by imperfect focalization and must not be confounded with the obliquity caused by the prismatic deflection *assumed* by Drs. Savage, Lippincott and others. While I deny the existence of the latter *obliquity*, I am the last person to deny the *distortion* of the retinal images; for I regard the distortion of the image of a light point as the most valuable sign for detecting astigmatism, and have for many years made the best practical use of it in my astigmometer.

F. C. HORTZ, M.D.

### A Simple and Effective Method of Treatment in Purulent Conjunctivitis of Infants.

INDIANAPOLIS, IND., March 25, 1895.

To the Editor:—Twenty-five years of eye-practice, private, and in hospital, has given me abundant opportunity to test the relative merits of the different methods of treatment in suppurative conjunctivitis of infants.

Until about one year ago it was my belief that nitrate of silver, when properly applied, was the most reliable of all medicines in this dangerous disease. In my hands, as well as in those of my professional brethren with whom I am intimately acquainted, it has never failed to cure, if begun before ulceration of the cornea has taken place.

To properly apply it does not mean to drop it into the eye, one or more times daily, as it would by such a method be

too irritating, if used of sufficient strength to control the suppurative process. It must be applied with a camel's hair pencil to the thoroughly everted palpebral and reflected portion of the conjunctiva, and then washed off, without suffering it to come in contact with the cornea, as strong as 10 to 40 grains to the ounce of water, according to the gravity of the case, or the profuseness of the discharge.

How many physicians are there who can properly evert the lids of a newly born infant? This question can only be answered by those who have tried it. To carry out this method of treatment until the case is cured, it is necessary that the physician make the application himself, once in every twenty-four hours. It dare not be given over to a nurse or parent, and it has to be kept up from two to six weeks.

Let us compare the above difficult but almost certain method to a more simple and easily practiced one, which was introduced by Dr. X. C. Scott, of Cleveland, who presented it to the AMERICAN MEDICAL ASSOCIATION at its last annual meeting. It is as follows:

Hydrastia sulph.	}	. . . . . grs. v.
Acid boric		
Sodii bi-borat		
Tinct. opii deod.		
Aquæ dest.		3j.
Mix and filter.		

Dr. Scott has the eye cleansed every twenty minutes and cold compresses applied when required. He then has the above solution injected into the upper and lower conjunctival sacs, about six times a day, by means of a medicine dropper with a nozzle long, smooth, and strong enough to be easily introduced beneath the upper lid without breaking. Once a day he used, in addition to this, a 1 per cent. solution of silver nitrate to the inner surface of the lids. (He tells me that he does not use the silver now.)

It will be seen by those who have read the discussion which followed his paper, that nearly all of the gentlemen present gave all of the credit to the silver treatment. They seemed to ignore the fact that the cases got well in about one-fifth of the time usual to the silver treatment alone. It was my fortune to hear from Dr. Scott's own lips all about this method several months before he read the paper to the society. I tried it on a case a few days afterward. It was a very severe one occurring in both eyes, one of which had ulceration of the cornea. I gave a very grave prognosis. A 20 grain solution of silver was applied to the everted conjunctivæ and the yellow root solution was given to the nurse, to be dropped into the eyes every hour afterward. On visiting the hospital the next day I was surprised to find that the discharge of pus had nearly ceased. I therefore simply had the yellow collyrium used every hour, for a few days, and in ten days the child was cured, except the ulcer, which at this date is well and only a small opacity remains.

I have treated several very bad cases since then; all of them were cured inside of two weeks. All that seems to be necessary is to inject it under the lids every hour, cleanse the eyes still more often with tepid water, and use every night a little vaselin on the edges of the lids. They should be watched by the physician to see that nothing goes wrong, and he should be sure to see that ulceration of the cornea did not exist before the treatment was begun.

A greater boon never was given to the busy physician than this one of Dr. Scott. It will save many a child from blindness.

J. L. THOMPSON, M.D.

The Forty-sixth Annual Session of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

### A Wise and Able Governor.

LITTLE ROCK, ARK., March 23, 1895.

*To the Editor:*—I inclose herewith a cutting from the *Little Rock Daily Gazette* of this date. Up to two years ago a law had been in operation in this State, regulating the practice of medicine. It provided for a medical board in each county (about seventy-five of them) consisting of three "physicians," who were appointed by the county judges. They gave certificates of qualification to any and everybody who applied for them, and these "certificates," when once obtained, were good forever, and permitted the holder to practice medicine anywhere in the State. Two years ago this law was repealed and an Act was passed which required that all persons beginning practice after that date should be graduates of some reputable medical college, having not less than two full courses of lectures as a minimum requirement for graduation.

It was a bill repealing this Act and reestablishing the old county boards (with slight modifications) that the Governor vetoed and which the House of Representatives promptly passed over his veto.<sup>1</sup>

It is so unusual for an executive of a State, or any one else high in authority, to take such lofty grounds in favor of advanced medical education, that I believe it to be the duty of every intelligent physician to uphold and defend Governor Clark, and I thus pointedly call your attention to the matter, that you may give it such editorial notice as it merits.

Very respectfully,

J. A. DIBRELL JR.

### Pure Air for Cities.

MILTON, KY., March 23, 1895.

*To the Editor:*—I believe it is entirely practicable to supply cities with air from an altitude of five hundred to a thousand feet, by means of an upright conical cylinder, a force-and-suction air pump, and pipes leading to sleeping and other apartments in the city.

Will you kindly express your opinion upon this subject, and whether it would be of interest to our ASSOCIATION to have the plans and specifications published in our JOURNAL?

Respectfully, S. E. HAMPTON, M.A.M.

ANSWER:—The scheme is practicable. Let us have the plans.

## NECROLOGY.

DARWIN G. EATON, M.D., of Brooklyn, died March 17, in his seventy-third year. He was for many years the Professor of Chemistry in the Long Island College Hospital, for which services recognition was given in 1864, by an honorary degree in medicine in that school. He was for a time President of another Brooklyn institution, the well-known Packer Institute, and his standing among men of learning and educators was in the foremost rank. Many hundreds of physicians received their drill in chemistry at his hands. He was a man greatly respected by his pupils.

CHARLES L. HOGEBOOM, M.D., of Brooklyn, died March 12, aged 68 years. He was formerly and until a few years ago a resident of Lawrence, Long Island. He was a Hollander by descent and educated in New York City; the College of Physicians and Surgeons gave him his degree in 1851. He was well versed in surgery, and stronger yet in public medicine, but his great forte in recent years had been that branch of sculpture that finds expression in the bas-relief. His portraitures in plaster, clay and bronze of Irving, Bryant, Jefferson, Franklin and of certain living people of eminence, as well as bas-reliefs of imaginative creations, were a labor

of love. The following is a portion of an affectionate tribute to his worth that was penned by one of the editors of the *Brooklyn Eagle*:

"Dr. Hogeboom did not represent the proverb of 'effective in much, but eminent in nothing.' Effective in much he was, eminent in medicine, surgery, sculpture and engraving and in scientific authorship he also was. The worlds of art, of learning and of literature were more familiar to him and he was more at home in them than could be said of the world of affairs. His outlook on politics, parties and contests for political power was ingenuous to childlikeness, but was marked by candor, purity and faith. He will long be remembered and profoundly regretted by a large circle of professional and personal friends."

GUSTAV WEBER BRATENAH, M.D., of New York City, died March 18, at the early age of 28 years. He was a native of Cleveland, Ohio, a graduate at the College of Physicians and Surgeons, and an ex-interne of the Nursery and Children's Hospital, New York. He held a similar berth at the Sloane Maternity Hospital and at the Roosevelt. In 1891, he spent a year abroad in the foreign clinics, seeking the best masters and methods in order to fit himself for practice and for teaching. His death is ascribed to tuberculosis.

HENRY C. LICHTENTHALER, M.D., March 19, 1895, at Lock Haven, Pa., of typhoid pneumonia, aged 34 years. Dr. Lichtenthaler was born in Lock Haven in 1860 and was a son of the late Dr. H. A. Lichtenthaler. He graduated at the University of Pennsylvania in 1882 and three years later settled in Larned, Kan., where he practiced his profession until 1890 when he returned to Lock Haven. Dr. Lichtenthaler was Secretary of the Clinton County (Pa.) Medical Society and of the West Branch Medical Association. He was City Physician, Coroner of Clinton County and member of the Lock Haven Board of Health. He was a painstaking, honorable competent physician, respected and loved by his profession and patrons.

ELLA M. ANDERSON, M.D., lost her life March 8, in the *Longfellow* wreck on the Ohio River. She was formerly employed at the Ward's Island Insane Asylum, of New York County, as fifth assistant physician on the female side. She was on duty the 5th of the month, at which time she was given a two weeks leave of absence. She appears to have been in attendance upon an invalid, whose life was also lost in the collision.

STEPHEN WALLACE BOWLES, M.D., of Springfield, Mass. died Feb. 12, 1895, aged 59 years. He was a graduate in medicine of the College of Physicians and Surgeons, New York, of the class of 1859, and a member of his State Medical Society since 1876.

RICHARD BLACKWELL MERSHOM, M.D., of Newark, N. J., died March 22, 1895. He was one of the oldest and best-known of the physicians of his State, and had been in feeble health for several years. He was 83 years old, having been born in Lawrenceville, N. J., Jan. 12, 1812. He was graduated from Princeton College in 1834, and five years later from the Jefferson Medical College of Philadelphia. He removed to Newark in 1850 and took up the practice of medicine, having his office in the building where he died. He leaves four daughters, his wife having died about twenty years ago.

A. B. PITZER, M.D., of Tipton, Ind., March 22.—Ralph Harris, M.D., of Macomb, Ill., March 19, aged 82.—J. J. Martin, M.D., of Pittsburg, March 14.—P. A. Skiff, M.D., of Utica, N. Y., March 13, aged 68.—James Youmans, M.D., of Davenport, Iowa, March 16, aged 69.—S. D. Rodgers, of Oakdale, Tenn., March 14.—W. H. Lanoix, of Quincy, Ill., March 18, aged 51.—C. V. Barclay, M.D., Chattanooga, Tenn., March 21.—A. S. Grigsby, M.D., of Marion, Ark., March 16.—W. N. King, M.D., of Abilene, Kan., March 19, aged 69.—D. B. Allen, M.D., of Warsaw, Ky., March 26, aged 46.—Joseph Love, M.D., of Savanna, Ill., March 24, aged 52.—T. C. V. Barkley, M.D., Chattanooga, Tenn., March 21. The Chattanooga Medical Society held a meeting March 22 and passed appropriate resolutions.—S. T. Brooks, M.D., St. Johnsbury, Vt., March 20, aged 72.

<sup>1</sup> And was also passed by the Senate.

## ASSOCIATION NEWS.

**Section on Physiology.**—Dr. E. H. Woolsey, the President of the Section, requests that those having papers on electricity and its medical applications read them in this Section, if circumstances will permit. At the last meeting interesting papers on electricity were read in this Section, with illustrative demonstrations on animals. It is especially appropriate that the physiologic relations of electricity be discussed here. Several important and interesting papers have been promised for this Section.

Dr. Ephraim Cutter, of New York, will read a paper on Food and Thrombosis; Dr. J. Mount Bleyer, of New York, offers elaborate demonstrations of some novel applications of the kinetograph, to accompany a paper entitled, Researches in Rapid Photography by means of Edison's Kinetograph; and the animated Reproduction by the Kinetoscope; showing also by this method the present and future possibilities of taking and reproducing certain animated

## PUBLIC HEALTH.

**Sanitation and Cholera.**—To the improvement of the sanitary conditions in India within the past few years is attributed a reduction in the annual average of deaths from Asiatic cholera from 43,000 to less than 19,000.

**A Growsome Connection.**—The prevalence of contagious diseases in the New York City schools has led to comment and investigations. As a result of one of these it has been developed that of 112 school trustees 23, or a little less than 20 per cent., are undertakers. The *New York Times* says: "The fact is suggestive; it would be amusing if it were not so tragical."

**Infectious Stage of Smallpox.**—It is understood to be a practical working axiom among medical officers of health, in this country at least, that smallpox is not infectious until the eruption appears. Dr. N. Von Arx, House Physician to the Olten Kantonspital, furnishes to the *Correspondenz-Blatt fuer Schweizer Aerzte* the details of a case in which it would

## AMERICAN MEDICAL ASSOCIATION FORTY-SIXTH ANNUAL MEETING.

Music Hall.

Museum of Exhibits.

BALTIMORE, MD., MAY 7, 8, 9 AND 10, 1895.

physiologic movements of the larynx, heart, intestines, etc., and certain diseases having visible symptoms, etc., with a historical review of fifty years of photography.

Dr. E. H. Woolsey will read a paper on the Physiologic and Pathologic Effects of Electricity, and also some notes on Practical Experience with Electricity.

Dr. Charles Gilbert Chaddock, of St. Louis, will read a paper on the Physiology of Instinct.

Those having papers to present in this Section will kindly forward titles immediately to Dr. C. G. Chaddock, Secretary 2900 Washington Avenue, St. Louis, Mo.

**Section on Ophthalmology.**—The officers of the Section will be unable to arrange for the reading of any more papers than have already been promised for the meeting at Baltimore.

EDWARD JACKSON, Chairman.

Denver, Colo., March 20, 1895.

**Proposed Botanical Garden for New York City.**—It is proposed to raise \$250,000 for a garden in one of the public parks of New York City. It is reported that more than \$200,000 have been privately subscribed for that purpose. When the other fifth shall have been raised the aid of the city will be demanded. Bronx River Park has been selected as the preferable place for the garden. Among those who are interested in the undertaking are Seth Low, Cornelius Vanderbilt and Bishop Potter.

appear that the disease was contracted from a patient during the febrile stage and fully forty-eight hours before the first traces of smallpox rash were discovered. The details are so full as to leave no room for doubt as to the infection of a second patient from the first, and that transmission of the contagion took place before any cutaneous manifestations of smallpox had developed.

**To Protect the Public Against Spurious Antitoxin.**—A bill has been introduced in the Connecticut Legislature for the protection of the public against inefficient and false diphtheria-antitoxins, some of which have already been offered for sale by unscrupulous dealers. The bill provides that some authoritative guarantee for quality must be supplied for all of the remedy that is put on the market in that State.

**Case of Leprosy at New York.**—Some considerable notoriety has arisen in connection with the case of the leper C. G., reported in this JOURNAL, on March 16, on account of the discovery by the New York City Board of Health that the case has not been reported, although under observation at intervals for six years. Dr. Ashmead is reported as taking the position that he had not been called in to treat the patient; that he had at no time prescribed for him, and that there was no law requiring him to report the case to the city authorities. He had reported the case to the Supervising

Surgeon-General of the Marine-Hospital Service in the hope that the patient might be provided for in some way so that his family would not suffer harm. In the course of the past six years he had been at intervals an inmate of a tenement house, wherein dwell twenty families, besides his own. He has been a steamship employee, serving as cook, waiter or storekeeper to some of the lines doing business with the South American ports.

**Scavengers of the Sea.**—Our British confrères continue to be agitated over the "typhoid oyster" and the columns of their lay and professional press are flooded with communications on the subject. The effect has been to injure the oyster trade very seriously and all manner of suggestions are made as to the future regulation of this industry. It is not quite clear, however, that what an Ann Arbor professor calls these "scavengers of the sea" are really responsible *per se* for the manifold ills attributed to them. That an oyster shell may hold typhoid-polluted water is probably true; so also may a glass vessel. Of themselves, oysters have been proved to be destructive of pathogenic bacteria. Mrs. Percy Frankland furnishes a note to *Nature* recalling some of the experiments of her husband, the Professor, as well as those of De Giaksa, on this subject. In the greater bulk of experiments made with oysters and some varieties of mussels replaced in sea water after inoculation through a hole in the shell, which was afterward sealed up, the pathogenic microbes entirely disappeared in six hours; in only two instances were they detected in small numbers at the end of twenty-four hours, and in no case were they identified after forty-eight hours. It is the transplanting of oysters to sewage-contaminated waters or their storage where such contamination ensues, which is responsible for the recent attacks on the good name and fame of these succulent morsels.

**Health Reports.**—Sanitary reports to the Supervising Surgeon-General of the Marine-Hospital Service:

#### CHOLERA—FOREIGN.

Austro-Hungary: No cholera cases or deaths. Totals from April 7, 1894 (beginning of epidemic) to Feb. 17, 1895, 15,318 cases, 8,393 deaths.

Russia: Radow Gov't, January 20 to 26, 1 death; Suwalki Gov't, January 20 to 26, 5 cases, 3 deaths; Koono Gov't, January 20 to 21, 1 case, 1 death; Kurland Gov't, January 13 to 26, 6 cases, 2 deaths; Volhynia Gov't, January 13 to 26, 25 cases, 12 deaths; Podolia Gov't, January 20 to February 2, 105 cases, 45 deaths; Taurien Gov't, January 13 to 26, 1 death; Kursk Gov't, January 13 to 19, 1 case.

Turkey: Constantinople, February 11 to 19, 75 cases, 38 deaths; Adalia, February 4 to 18, 17 cases, 11 deaths.

India: Calcutta, February 2 to 9, 34 cases; Madras, February 9 to 15, 4 cases.

#### YELLOW FEVER—FOREIGN.

Cuba: Havana, March 7 to 14, 3 cases.

#### SMALLPOX—UNITED STATES.

Connecticut: New Haven, March 16, 1 case varioloid.

Louisiana: New Orleans, March 9 to 21, 3 cases.

Michigan: March 9 to 16, smallpox reported at Detroit, Grand Rapids, Highland Park, Three Rivers and Ypsilanti.

New York: Brooklyn, March 16 to 23, 1 case.

Ohio: Cincinnati, March 15 to 22, 11 cases, 2 deaths.

Pennsylvania: Philadelphia, March 9 to 16, 8 cases, 2 deaths.

Texas: Fort Worth, March 9 to 16, 4 cases.

Wisconsin: Sparta, March 9 to 16, 5 cases (in county jail); Milwaukee, March 9 to 16, 2 cases, 1 death.

Virginia: Portsmouth, March 13, 1 case varioloid (at Naval Hospital).

#### SMALLPOX—FOREIGN.

Cuba: Havana, March 7 to 14, 2 deaths.

Ecuador: Guayaquil, February 21 to March 8, 3 deaths.

England: Leeds, March 2 to 9, 2 cases; Liverpool, March 2 to 9, 2 cases; Derby, March 2 to 9, 1 death.

Egypt: Alexandria, February 5 to 18, 4 deaths; Cairo, February 5 to 18, 2 deaths.

Gibraltar, February 25 to March 3, 1 case.

Holland: Rotterdam, March 2 to 9, 10 cases, 3 deaths.

India: Calcutta, February 2 to 9, 60 deaths.

Ireland: Dublin, February 23 to March 2, 4 deaths.

Italy: Bologna, March 2 to 9, 3 cases; Marsala, February 23 to March 2, 1 death.

Russia: Batoom, February 19 to 26, 2 deaths; Moscow, February 16 to March 2, 2 cases, 2 deaths; Odessa, February 16 to 23, 2 cases; St. Petersburg, February 16 to 23, 6 cases, 2 deaths.

Scotland: Edinburgh, March 2 to 9, 2 deaths; Glasgow, March 2 to 9, 1 death.

Switzerland: Basel, February 16 to March 2, 17 cases.

Uruguay: Montevideo, February 9 to 16, 4 cases.

## MISCELLANY.

**Montefiore Home for Chronic Invalids.**—This charitable retreat of New York City has received gifts amounting to not less than \$50,000 toward a fund for the establishment of a country home, chiefly for persons in the early stages of tuberculosis, to be situated in the Adirondacks or at Vineland.

**Another "Faith-Cure" Victim.**—The 10-year-old granddaughter of the late Congressman Geo. W. Houck, of Ohio, died on the 18th inst. under the care of a Christian scientist and his wife. She was suffering from typhoid fever and received no medical or other attention save that furnished by the "faith cure."

**Boston Hospitals Receive Bequests.**—The late Moses Kimball, the founder of the Boston Museum, leaves to the New England Hospital for Women and Children the sum of \$21,000; \$5,000 to the Massachusetts Charitable Eye and Ear Infirmary, and a like sum to the Boston Dispensary, as well as to a number of homes and charitable societies.

**An Old Joke in New Guise.**—The New York *Herald* is responsible for reviving this hard saying:

"Druggist—What the dickens have you rung me up for at 1 o'clock in the morning?"

"The Tattooed Man—Don't git hot, boss. I only want a little morphin for the ossified woman. She's dyin' terrible hard."

**Sanitarium for Consumptives.**—At Liberty, N. Y., there will soon be built a new rural retreat for consumptives, for which purpose \$20,000 has been contributed by Mr. J. Pierpont Morgan. The location has a high reputation for salubrity and attractiveness. Its easy accessibility to a large population, needing a sanitary retreat less remote from the metropolitan district than are the Adirondacks, will tend to build it up even more rapidly than that on the Saranac.

**New York Medical Missionary Training Institute.**—This school, conducted by Dr. George D. Dowkontt, in East Forty-fifth Street, New York, has been able to purchase a valuable property of twenty acres, formerly the home of the noted car-builder, the late John Stephenson. His house or castle is located at New Rochelle and overlooks the Long Island Sound. The building, 115 by 60 feet, will serve for the housing of seventy students with their teachers. In the near future, if the work prospers as in the past, there will be erected other halls. The price paid was not far from \$90,000.

**The Bill for Corporal Punishment in Criminal Assault Cases (New York Legislature).**—In the New York Senate, the so-called "whipping-post law" has been adopted, almost without dissent, under the urgent advocacy of the Society for the Prevention of Cruelty to Children. There is little doubt that it will quickly pass the Assembly and receive the signature of the Governor. In order to make the bill go through quickly, it was found necessary to omit wife-beating as an offense punishable by the lash. The ground that was taken, in this particular, was that if this crime was included it would make reconciliation between the wife-beater and his wife impossible. The result will doubtless be seen in an

increase of brutality toward wives by drunken husbands, while at the same time the crime of assault on little girls will be repressed.

**Another Jubilee Hospital.**—The medical profession of Vienna proposes to commemorate the fiftieth year of the reign of the Emperor, Francis Joseph of Austria, by the foundation of a hospital for children with a capacity of 1,000 beds. The Emperor succeeded to the throne in 1848; it is doubtful, therefore, whether this gigantic monument may be realized to mark the fiftieth year of his reign; but there is much enthusiasm for the project and its completion is confidently anticipated.

**"Let the Inebriate Smile Again." A Hint from Norway.**—A valuable hint comes to us from Norway. The way seems to be opening up for a form of moderate excise legislation that will in the long run be in the best interests of the lovers of alcohol. In Christiania, the capital of that land, no sale of beer or spirits is now permitted from Saturday afternoon to Monday morning, except to permanent guests residing at respectable cafés. This regulation has led to such a great diminution in the consumption of drinkables that the publicans have begun to complain that the liquor trade is no longer profitable. One day's break in the week is enough to show a great many imbibers the advantages of abstinence, even if it be limited in duration.

**Necessity of Frequent Visits.**—The Supreme Court of California (Todd v. Myers, 40 Cal., 355) in an action brought by a physician for professional services—the defense being that the visits were too frequent and not necessary—rules that "the defendant having admitted the employment of the plaintiff as a physician to treat his wife and children, the plaintiff was the proper judge of the necessity of frequent visits, and in the absence of proof to the contrary, the court will presume that all the professional visits made were deemed necessary and were properly made. It would be a dangerous doctrine for the sick to require a physician to be able to prove the necessity of each visit before he can recover for his services. This is necessarily a matter of judgment and one concerning which no one save the attending physician can decide. It depends not only upon the condition of the patient, but in some degree upon the course of treatment adopted."

**An Attempt at Discipline Fails.**—In the Kings County Medical Society, N. Y., an attempt was made in March to bring to book a certain member who had been charged with having transcended the by-laws of that society, in the matter and manner of his publications on the opium habit and similar topics. The council of the society consisted of the following officers: Drs. George McNaughton, President; Joseph H. Hart, Vice-President; David Myerle, Secretary; William C. Braislín, Assistant Secretary; Charles N. Cox, Treasurer; O. A. Gordon, Assistant Treasurer; William Browning, Librarian; Joel W. Hyde, George E. Law, W. W. Browning, J. M. Warfield and Glen R. Butler, Censors; W. B. Chase, Frank E. West, Charles Jewett, Z. Taylor Emery and Isaac H. Barber, Trustees, brought in the charges and a recommendation for suspension of one year. The matter was debated and brought to a vote, whereby the council suffered defeat. In order to sustain the charges a two-thirds vote was required; this number was not quite reached. The council lacked two votes. This society at its last anniversary meeting re-enacted its fealty to the Code of the AMERICAN MEDICAL ASSOCIATION, while retaining its delegate relations to the State Medical Society, which has abrogated the AMERICAN and all other codes.

**New York Commission in Lunacy.**—The Governor of New York has re-nominated, as Commissioner of Lunacy for the State, Dr. Carlos F. MacDonald, formerly the Superintendent of

the State Asylum for Insane Criminals at Auburn. The Commission contains two lay members and one physician. These members have been, in the main, working together harmoniously and to the manifest improvement in the lot and condition of the pauper lunatics that have hitherto been at the mercy of the so-called "county care." Dr. MacDonald is, if we mistake not, the originator of the term "State care," and the practical developer of the idea itself. An editorial writer has said of him and his colleagues that "the delicate, important and comprehensive work under their charge has been so well done by them that the thought of undoing it has become incredible, and the demand for its continuance and full completion has become irresistible. Governor Morton has done nothing better than this appointment and he will do nothing better than it." Dr. MacDonald was graduated by Bellevue Hospital Medical College in 1869. He has written comparatively little, but the neurologic journals have contained his views on malingering, traumatic insanity and surgery of the head in epilepsy.

**The New York Orthopedic Hospital.**—The twenty-seventh annual report of this charity is a well illustrated pamphlet. The Surgeon-in-Charge speaks of new and enlarged quarters that have contributed to an increased volume of charitable treatments. The total of visits were 17,500, comprising patients having almost every deformity to which childhood is heir. Dr. Shaffer regrets that the institution is restricted to children of an age between 4 and 14 years. In other words, the adolescents who apply for relief can not be accommodated. Scarcely a week goes by that he does not have to turn away youths and misses between 14 and 20 years old, whose actual need for hospital treatment is quite as great as in the case of those of lesser age, whom his rules allow him to admit. The expense account for instruments and plant and mechanical labor is very heavy, not less than \$9,300; a repayment of \$2,800 for braces, etc., leaves yet unpaid one of the most costly branches of Dr. Shaffer's work; salaries alone to machinists are nearly \$6,000. The report states that the sum of \$4,000 has recently been donated to the Hospital for the erection of a modern operating room, the want of which has been grievously felt a long time.

**Facitious Buchu.**—The *Medical Age* states that a certain patient Buchu nostrum at one time afforded a business of \$3,000,000 a year. The writer states further that he has in his possession the formula of that nostrum, in Helmbold's own handwriting. Its directions are to make a weak infusion of buchu and barberry leaves, sweetened with New Orleans molasses, colored with burnt sugar, and preserved by adding 16 per cent. tincture of cubebs to the mixture. To this was also added a small proportion of essence of peppermint to give the compound "that peculiar characteristic odor and taste of mint which distinguished genuine buchu preparations." The latter idea was derived from the description, in the United States Dispensatory, of buchu leaves, which states that "the odor is strong, diffusive, and somewhat aromatic, their taste bitterish, and analogous to mint." The fact that such a compound as this could be exploited successfully and its sale acquire such enormous proportions shows plainly the power of newspaper advertising. Helmbold had the ability, however, of securing a great deal of gratuitous advertising. His lavish style of living—his coach and four—his establishment at Long Branch—his so-called liberality by which he gave away pictures costing \$20 apiece—all of these were used with consummate shrewdness for advertising purposes until the mention of Helmbold's eccentric doings became as much a part of the daily news as the accounts of base ball and yacht races.

**Nitrate of Silver in the Treatment of Burns.**—In cases of burns in the second degree, von Bardeleben (*La Semaine Médicale*) uses a 1 per cent. solution of nitrate of silver in connection with sub-nitrate of bismuth. After excising the blisters, the denuded surface is washed with a salt solution, 0.06 per cent., then with the nitrate; the surface is next dusted with bismuth and covered with cotton. Each time that the dressing is changed the wounds from which the eschars have separated should be treated anew with the nitrate of silver

This method is preferable to the ordinary dressing of bismuth, for it considerably diminishes the secretion, favors the formation of the eschars and thus facilitates recovery. It must, however, be cautiously employed. Von Bardeleben has observed a fatal case of argyria in a woman with enormous burns which had been treated with nitrate of silver and bismuth. In the course of the treatment the patient was attacked with a grave form of stomatitis which improved somewhat but did not entirely disappear. In nine weeks more, during which time the silver was used as a dressing, there was an acute exacerbation of the stomatitis; the buccal mucous membrane presented patches with bluish reflections; the patient had diarrhea, vertigo and convulsions and succumbed in eight days. At the necropsy, black deposits were found in the *cul-de-sac* of Douglas and in the large intestine, which deposits, as well as those in the mouth, gave the usual reactions for silver.

**"Look Your Best."**—The *Medical Examiner* gives place to the following paragraph as a short sermon on the dress of physicians. The admonition was originally addressed to a meeting of life insurance men, held at Little Rock, Ark., by Professor Stewart, of the Mutual Life Company. The modern requirements of city life, at least, confirm the statement that the best invites the best:

"In the progress of to-day two conditions are essential to the highest community success, and these are community activity and community dress. As the individual must appear in the garb of good society if he would enter it, so must the city. The universal deference is to clothes, and there is no condition of physical life, save that of man, that does not perennially put on a new garb; and the larger divisions of the family do so with great toil and pain. The birds molt their feathers, the animals shed their hair, and even the snake pulls off his earth-worn skin. Flowers and trees, and even the solemn pine are no exceptions to nature's law of embellishment, but dress in the fashions of their season's change. The behoof to dress your best is set on the surface of all present life; cities or individuals, the wisdom is the same. To look your best is to invite the best, and the best is life's only ultimate, let man deny it as he will."

**The Ordeal Poison of Central Africa.**—An English missionary stationed in Central Africa, sends home an account of an exciting adventure which he had in securing a large amount of "mwavé" or ordeal poison. He took possession of four packages in defiance of quite a number of natives armed with spears and shields, and conveyed it to his station. The poison, in the form of the bark of a tree, was packed in two flat baskets and two baboon skins, weighing seven to ten pounds each. Of his examination of these parcels he writes as follows: "We opened up the two baboon skins (mwavé bark is generally carried in these) and found a lot of mwavé bark, a little toy mortar, a hippo-tooth pestle for pulverizing the bark, the two drinking cups, and the medicine stick for marking off the line which divides those who have to drink the mwavé from those who have not. There was also a thin strip of cloth, which my boys told me had been taken from a person who died from the effects of the poison. I weighed the bark, and found there were thirty-four pounds—no small quantity, sufficient to kill many people. It is a deadly poison, and kills people within an hour and a half after drinking it. Birds die if they eat the leaves, and insects if they suck the flower. The Angoni pay large prices in cattle or slaves to those who bring them the mwavé. It is said to come from the Blantyre district, but few natives know the tree."

The local references in the latter part of the above paragraph apply to the tribes and country west and south of Lake Nyassa. The term "mwavé," is probably identical with the better known "mboundon," which is another ordeal bark, derived from a tree or trees of the *Strychnos* group. This source may be allied to the scarcely less notable plants,

from which the South American Indians prepare their woorara poison. Du Chaillu has stated that certain of the tribes of west equatorial Africa use the *root* for the preparation of the mboundon potion, prizing it as an ordeal and for the purposes of divination. Death is often produced by it within five minutes; the blood gushing from the mouth, eyes and nose. Where vomiting is promptly produced the accused person probably recovers and is considered to have been acquitted.

**On Malaria as a Waterborne Disease.**—The *New Orleans Medical and Surgical Journal*, June, 1892, contained an article by Dr. Richard Waggoner, of Pensacola, that illustrates very plainly the affirmative side of the question, "Is Malaria a Waterborne Disease?" The following is an extract therefrom:

"The writer has resided, during the past five years on the Naval Reservation near Pensacola, Fla., serving as Apothecary at the Pensacola Naval Hospital. The Naval and Army Reservations are situated on the north side of Pensacola Bay, about seven miles southwest of the city of Pensacola, and about one and one-half miles from the Gulf. The Navy Yard, the villages of Warrington and Woolsey lying just without its walls, and the Naval Hospital, three-quarters of a mile west, are situated on the Naval Reservation, and Fort Barrancasis, situated on the Army Reservation, one mile west of the Navy Yard."

"The villages of Warrington and Woolsey are at the present day extremely unhealthy places, being strongly malarious throughout the whole year, and especially so during the summer and autumn. This condition of affairs has existed during the whole period of my residence there, but the older inhabitants all unite in declaring that previous to about the year 1872 the place was considered very healthful, that chills and fever were unknown, and that people from the interior would locate there to recuperate from malarial troubles. After carefully investigating the matter, I have concluded that the water supply of the villages in question is the source of the greater part of the malarial poison, because the only change of a sanitary nature which has occurred to them consists in their water supply, and in this they have made a very decided change. The villages are the offspring of the Navy Yard, upon the location of which potable water was sought and evidently found, consisting of two springs at the foot of the rise alluded to above, which boiled up out of the pure white sand, clear and cool even during the hottest part of the summer. The authorities in the Yard, having at that time no reservoirs for collecting rain water, caused these two springs to be curbed in with brick for their own supply. These springs are still in existence, and are known as the 'Commodore's Springs.' This source supplied most of the drinking water to families residing in the villages, a small portion of them possessing cisterns, but preferring this water in summer on account of its coolness, until about the year 1872. About that time *driven wells* were introduced to them, and these being cheap, quickly put in operation and convenient, it was not long before almost every household had one or more of them in the back yard. The wells are driven, as a rule, only about twelve feet deep, some of them half that depth.

"Another fact: in January, 1886, a Marine Guard, numbering about forty men, arrived at the Pensacola Navy Yard for duty at that station. These men came directly from the North, and were in fine physical condition. During their first year on the station they began to have frank attacks of remittent and intermittent fever; during their second year there was a much larger proportion of them on the sick list, and between July 1 and August 15 of their third year (1888) every man in the Guard had an attack of either intermittent or remittent fever, twenty-five of the forty being in the hospital at one time.

"The annual report to the Surgeon-General for the year 1888, says: 'The health of the Marine Guard grew worse almost steadily during their stay here until in the early part of August, 1888, before the sickly season had reached its height, they broke down completely, and had to be carried away bag and baggage.'

"The water supply of the Navy Yard consists in a brick cistern for each of the officers' quarters, and three large cisterns, with a combined capacity of 500,000 gallons, affording the general supply. The Marines were supposed to get their drinking water from one of the large cisterns, the nearest of which is about 200 yards from the barracks, but

unfortunately for them there was a driven well very near their barracks, from which they derived the greater part of their drinking water. On the other hand, the officers and their families residing in the Yard used cistern water only, and they were entirely exempt from malarial diseases, sickness of any kind among them being little or none. At Fort Barrancas, only a mile from the Navy Yard, the enlisted men, more than double the number of the Marine Guard, used cistern water exclusively, and their health during the period of so much sickness among the Marines was excellent.

"The third fact is as follows: the present Naval Hospital buildings were constructed in 1875, on the foundations of the old hospital destroyed by fire during the civil war. The water supply consisted until the early spring of 1890, of two driven wells, eighteen feet deep. During the whole time this water was used the place was very unhealthful, the attendants having attacks of malarial fever every year, and patients admitted with other diseases would often develop malarial manifestations while at the hospital. During my first year at the hospital I apparently escaped the poison, but during the two succeeding years, 1888 and 1889, I had several attacks of malarial fever, my wife suffered from it even more than I, and our little girl, during her first and second summers, had typical paroxysms of intermittent fever. In the spring of 1890 an old brick cistern, a relic of the old hospital, was repaired and put in use, since which time we have used cistern water only at the hospital for drinking purposes, and there has not been the slightest evidence of malarial trouble of any kind in my family."

**A Court's Opinion of Insane Delusions.**—Until human nature radically changes, there will probably always be those who will seek some scapegoat for their crimes. At one time it may be one thing, and on another occasion something quite different. This explains much of the talk about irresistible impulse, hypnotism, insane delusions, and the like. In this connection, one of the most interesting of recent legal decisions is that of the Supreme Court of Tennessee in the case of *Wilcox v. State*, rendered Nov. 12, 1894. This was an appeal from a conviction of murder in the second degree. The defense relied on was the insanity of the defendant at the time of the homicide, it being insisted that the act was the result of an insane delusion upon his part, rather than a general derangement of his entire mental faculties upon matters generally. It was contended that when he did the killing he was suffering from the insane delusion that the deceased had been on too intimate terms with his wife. He had been addicted to the excessive use of morphin and cocaine, taking the drugs in doses sufficient to kill twenty men not addicted to their use, at a single dose; and he had carried on this habit for years, and had grown rapidly more and more addicted to their use, and come more and more under their influence. Many witnesses were examined, both experts and non-experts, in regard to his mental condition. It appeared that he was at one time a man of good mental capacity, described by many of the witnesses as an exceptionally bright man, that he was an active business man, had studied and practiced medicine with success, and was regarded universally as a man competent to attend to his business affairs. He was also shown to have been an arbitrary dictatorial man, of strong will power, and from his boyhood of quick, active, irritable temper. It was strongly pressed upon the court that many of his arbitrary and dictatorial acts were evidences, and the result, of his mental unsoundness and the strong hold which the drugs had obtained over his actions, and that the evidence presented a case of insane delusion, on account of which the verdict should not be upheld. But the court holds otherwise. Its answer is that in criminal cases the correct issue is not that of sanity, but of responsibility. The delusions of a sane man do not make him irresponsible. The question is in such cases, is the delusion set up as a defense the delusion of an insane person? Many men of strong minds, continues the court, have delusions. Remarkable instances are given in the works on medical jurisprudence of delusions in men of prominence in all the walks of life. Lord Kenyon had an un-

reasoning fear of poverty, and so did Lord Stowell, although he was a man of immense fortune, his home being absolutely destitute of the necessities and comforts of life. Lord Erskine would never sit at a table or remain in a company as one of thirteen persons. Lord Eldon, after he had made up his mind and expressed his opinion lucidly and conclusively, was at all times a prey to grave doubts of his correctness. Lord Brougham, upon more than one occasion, was placed in seclusion, his mind being clearly off balance. Judge Breckenridge, of Pennsylvania, is reported to have on a hot day, while holding court at Sunbury, gradually taken off his clothes, until he sat naked on the bench. Judge Baldwin, of the United States Supreme Court, was a hypochondriac. A distinguished New England judge imagined that a dropsical affection under which he labored was a sort of pregnancy. And yet none of these men were insane, because they had reason and sanity enough to conquer and overcome these delusions. A familiar illustration is that of the Mormon elders, who claimed that they had a direct revelation from heaven permitting them to practice and teach polygamy. The world generally regards this as a rank heresy, and the claim to be the evidence of an unreasonable delusion. It has, however, been held that they can not defend on the ground of such delusion, inasmuch as otherwise they are sane, shrewd, active, successful, and unusually practical men in their business and social relations, and they have been held responsible for such delusions. Nor can it be that the jealous suspicions which so many men entertain without any foundation can be magnified into insane delusions, which will exempt them from punishment for crimes originating in such jealousy. In a sense, all unfounded suspicions are delusions, but they do not for that reason excuse crime.

The rule is tersely stated in Archbold's "Criminal Practice and Pleading" as follows: "The insanity must have been of such a kind as entirely to deprive the prisoner of the use of reason, as applied to the act in question, and the knowledge that he was doing wrong in committing it. If, though somewhat deranged, he is able to distinguish right from wrong in his own case, and to know that he was doing wrong in the act which he committed, he is liable to the full punishment of his criminal acts."

Moreover, the court makes the point that the insanity set up as a defense in this case was not hereditary or natural, but voluntary, in the sense of having originated from the use of drugs. While this is an unfortunate and unhappy condition, the law, it says, does not and can not regard it with the same leniency that it does cases of adventitious insanity, not caused by the act of the party himself. Parties who persist in subjecting themselves to the persistent use and habit of taking alcoholic drink or other poisonous compounds and drugs can not expect the same forbearance and immunity from punishment as those bereft of reason by the act of God. Still it is admissible and proper to show the immoderate use of drugs or whisky, not to excuse crime, but to illustrate the mental condition, with a view to fixing the degree of the crime as it depends upon deliberation and cool malicious purpose.

### Society Notes.

**ILLINOIS STATE MEDICAL SOCIETY.**—Members of the Illinois State Medical Society desiring to attend the annual meeting of the AMERICAN MEDICAL ASSOCIATION as delegates, are requested to send their names at once to the Permanent Secretary.

THE seventh annual meeting of the Shelby County Medical Society will be held in Shelbyville, Ind., Monday, April 8, 1895.—The next meeting of the Washington State Medical Society will be held in Seattle, May 21, 22, and 23, 1895.

### LECTURES ON INTRACRANIAL SURGERY.

#### III—REMOVAL OF THE GASSERIAN GANGLION.

BY EMORY LANPHEAR, M.D., PH.D.

ST. LOUIS, MO.

Tic douloureux (prosopalgia, epileptiform neuralgia or Fothergill's neuralgia) usually is due to some disease of the trigeminal nerve in front of the ganglion of Gasser—frequently a low grade of neuritis, sometimes an atrophic process dependent upon an obliterative endarteritis of the vessels supplying the nerves. Occasionally the disease may be traced to trouble in the alveolus, when it can be easily remedied; but commonly no local cause can be discovered, internal medication proves useless and life becomes a burden to the sufferer. Under such circumstances, removal of the ganglion is justifiable.

Three methods of reaching the ganglion have been proposed:

1. Opening the middle fossa through the temporal region;

2. Ablation of the superior maxilla and trephining the base of the skull;

3. Entering the cranium through the pterygoid region.

Before discussing these methods it is well to recall the anatomic relations of the ganglion. The fifth or trifacial nerve arises by two roots: a small anterior or motor nerve for the muscles of mastication and a large posterior root which constitutes the great sensory nerve of the face, giving origin to the ophthalmic and superior maxillary nerves (both nerves of sensation only), and supplying the inferior maxillary with its sensory fibers; these two roots do not join immediately after leaving the pons Varolii, but pass side by side, forward to an oval opening in the dura on the upper border of the petrous bone and thence between the bone and dura to the apex of the petrous where is formed the semilunar or Gasserian ganglion upon the sensory root, the motor fibers passing beneath the ganglion to join the third (inferior maxillary) division just outside the skull. In its passage under the ganglion this motor root is accompanied by the superficial petrosal nerve. The ganglion itself is intimately adherent upon its upper surface to the dura, which is here divided into two layers to cover the ganglion; and hence is difficult of removal. From its anterior border there proceed:

1. The ophthalmic division which continues forward along the outer wall of the cavernous sinus, making its exit through the sphenoidal fissure as three distinct nerves to supply the orbit and upper part of the face; just after leaving the ganglion it receives its communicating filaments from the cavernous plexus of the sympathetic—a most important surgical point, as otherwise there would be inevitable

destruction of the eyeball after removal or destruction of the ganglion.

2. The superior maxillary division which passes out of the cranium through the foramen rotundum to be distributed to the middle portion of the face in numerous branches.

3. From the lower angle the sensory part of the inferior maxillary which leaves the cranium by the foramen ovale and joins the motor root; immediately afterward it divides into two large trunks (anterior and posterior) the various divisions of which give sensation to the lower part of the face and the mouth; the posterior or larger trunk gives rise to the auriculo-temporal, the lingual and the inferior dental—the latter especially of interest, as it must be the guide to the foramen ovale—hence it must be remembered as lying beneath the external pterygoid in its upper relations, but later between the internal lateral ligament and the ramus of the jaw, finally entering the dental foramen.

It may thus be seen that the ganglion lies in an almost inaccessible location, surrounded by vital structures and contiguous to the great vessels at the base of the brain. What is the best route to follow?

Victor Horsley practiced the first mentioned method in a case that died seven hours after operation, presumably from shock. He opened the skull in the temporal region, low down; incised the dura and lifted up the temporo-sphenoidal lobe so as to see the base of the skull in the middle fossa, illumination being secured by means of a small incandescent light; he then cut the root of the nerve near where it emerged from the pons, followed it through the dura and removed the ganglion from above. From a number of experiments upon the cadaver I am convinced that this is an operation of great difficulty as well as severity. Unless a large portion of bone be removed it is impossible to reach the root of the nerve behind the ganglion, or even the ganglion itself. In every attempt made there was so much compression of the brain in exposing the point of attack that I believed much harm might result in the living subject—at least in hands less skilled than Mr. Horsley's. And it appears to me that there is great danger of hemorrhage from the contiguous sinus or artery; to which point I will refer later.

The second method has been followed by Mr. Rose, of London, with success in one case. But while by excision of the superior maxilla upon one side the foramen ovale may be quite readily reached, the disk of bone removed and the ganglion destroyed, the mutilation is too great to justify the procedure provided any other route can be utilized.

The third plan—known as the Rose operation—has proved, experimentally, to be decidedly the best. And the results in actual work have thus far been entirely satisfactory. Rose of London, Andrews of Chicago, myself, Park of Buffalo, and Parkhill of

Denver have, in the order named, operated successfully; and lately a number of other operators have recorded brilliant results, bringing the cases up to the neighborhood of twenty with only one failure.

In this operation two things must be especially remembered: the ganglion lying just above and external to the internal carotid artery, by the slipping of an instrument fatal hemorrhage may occur; an assistant should therefore stand ready to tie the common carotid upon the same side in case of accident while the operator prevents bleeding by gauze pressure. Second, since division of the fifth nerve (or its branches) *just in front of the ganglion* is said to give rise to destruction of the parts supplied by it and subsequent death, the ganglion must be totally extirpated without traction from the front, or the nerve must be cut *behind* the ganglion.

#### THE ROSE OPERATION.

The instruments required are: one scalpel of medium size; two scissors, one large, one small; half inch trephine with a long handle; one periosteal elevator; Hey's saw; bone drill and silver wire; dissecting forceps; one small curette (Volkmann's sharp spoon); two hooks to catch the nerve-blunt; one Liston bone forceps; twelve hemostatics. All should be metal so as to permit boiling. Last: needles and sterilized catgut.

After the usual preparation by bath, catharsis, etc., the head and face are carefully shaved; the parts thoroughly scrubbed with soap and water, dried and washed with sulphuric ether. The eye upon the affected side is irrigated with bichlorid solution, 1 to 3000, and the lids stitched together with fine catgut; the ear is cleansed and packed with a little gauze. At this point the hands of the operator and his two assistants must be again thoroughly scrubbed, the nails cleaned, and sterilization effected by washing the hands and forearms in saturated solution of potassium permanganate until a deep brown, decolorizing with strong solution of oxalic acid and final rinsing in sublimate solution 1 to 1000. The field of operation is again washed with antiseptic soap and water and then with the bichlorid solution; and the surrounding parts covered with towels wrung out of hot bichlorid solution.

Beginning just below the outer angular process of the frontal bone, an incision is made along the upper border of the zygoma to its posterior extremity, and curving sharply downward, descends just in front of the ear and over the parotid to the angle of the jaw, thence along the horizontal ramus to the vicinity of the facial vessels. This flap of skin is dissected up, care being taken not to injure Steno's duct and the facial nerve. By making the incision in this manner there is gained a maximum of space with a minimum of disfigurement and no paralysis of the portio dura. A long silk ligature is passed through the flap and held by an assistant, the retracted flap being wrapped in bichlorid gauze for protection. The periosteum is now stripped from the zygoma and four holes drilled through the bone; two through the zygomatic process of the malar, and two close to the root of the zygoma; these drill holes should be about one-third of an inch apart and are to provide passage for silver wires to hold the parts in place after trephining. With the Hey's saw the zygoma is divided between the holes at either end, the anterior saw cut being directed obliquely downward and forward, the posterior one as far back as possible. The bone is turned

down with the masseter muscle attached, care being taken not to injure the muscular attachment on the inner surface, as future nutrition of the bone must for a time come through the muscle. The coronoid process of the inferior maxilla being thus exposed it may be cut away with the Liston bone forceps or the saw; the bone removed should be thrown away after separating from the temporal muscle, as no attempt is made to restore it to its position because atrophy and cicatricial contraction would interfere with movements of mastication. The temporal muscle is now turned up out of the way, exposing the pterygoids. The external pterygoid muscle is separated from the skull by the periosteal elevator and drawn downward. Search is made for the third division of the fifth nerve (the inferior maxillary) as it is the guide to the foramen ovale through which it makes its exit. When this can not be found dependence must be placed upon the bony landmarks; an assistant wholly unconnected with the operation should be at hand with a skull which can be carefully observed and corresponding points located upon the patient. It should be remembered that the foramen ovale lies about one-fourth of an inch anterior to and the same distance internal to the foramen spinosum through which passes the middle meningeal artery, and a little more than a half inch behind and a trifle external to the foramen rotundum; so that any of these foramina is a guide to the others; further, the fossa for the ganglion lies about five-sixteenths of an inch internal to and slightly behind the foramen ovale, the carotid canal being the same distance from the foramen, directly toward the median line.

The situation of the foramen ovale having been determined, a half inch trephine with a long handle is introduced with the center-pin a little behind and external to the foramen. When the disk of bone is removed the hemorrhage must be checked by pressure for a moment, and the cavity cleaned from all blood, when the dura can be cut with scissors. A small incandescent light is now almost indispensable; by its aid a part of the ganglion can be seen. A small blunt hook is introduced, the nerve caught just where it *enters* the ganglion and strong traction made; when well in the opening it may be divided with small scissors and the ganglion torn out with dissecting forceps or a small curette. Hemorrhage is now quite severe but must not agitate the operator; it can be controlled by pressure or the application of a bichlorid gauze compress wrung from water of a temperature of 120 degrees. Bleeding having been arrested the wound is irrigated with hot sterilized water (or carbolic solution 1 to 40), the temporal muscle is tucked into the fossa and the zygoma replaced and wired. As no drainage can be employed the wound is now made as dry as possible, iodoform dusted in very freely, the incision rapidly closed with a continuous catgut suture, the face washed, the wound hidden in iodoform and much sublimate gauze applied. The head and affected side of the face must be covered with several layers of bichlorid gauze (1 to 2000), enveloped in cotton and bandaged tightly.

The most strict attention to even the minutest detail of asepsis is necessary at every step of the operation. There must be no break in the chain of ideal surgical cleanliness, regardless of any exciting incident which may arise.

Both eyes must be bandaged for four days and the

one on the affected side for two weeks. The catgut stitch in the lids is removed at the completion of the operation.

#### AFTER TREATMENT.

When put in bed the usual methods to combat shock must be instituted. Whenever much restlessness appears with the reaction, the hypodermatic injection of morphin (gr. .02) is indicated. Absolute quiet must be enjoined and vomiting prevented if possible. After the subsidence of nausea—probably in twenty-four to thirty-six hours—a liquid diet should be ordered and kept up for at least two weeks, at the end of which time articles easily masticated may be substituted.

About the sixth day the patient may be allowed to sit up, and on the twelfth or fourteenth to go about the house.

If (as is frequently the case) the subject has acquired the morphin habit it is best to stop the drug at the time of operation; surprisingly little discomfort will result, the disappearance of the pain giving partial relief from the craving. The hypodermatic injection of .005 doses of strychnin, three or four times daily, for a few days will greatly lessen the desire for the drug.

#### CASES.

That removal of the ganglion of Gasser does give permanent relief from the terrible pain is proved by the following case:

James S., of Chanute, Kan., age 54, came to me for examination in March, 1892. The family history and previous health were good; he was of strong constitution and non-syphilitic. Eighteen years ago he began to have paroxysms of pain in the right side of his face; the pain was thought to be neuralgic, and one by one all his teeth were extracted; morphin was used for the pain but gave no relief even in doses of a grain and was finally discontinued. During the two years preceding examination the local spasms had increased in frequency and severity until existence seemed unbearable and the patient had contemplated suicide to end his misery. All the coal-tar derivatives and other anodynes had been tried in vain. His appetite had been poor for some months, and as attempts at chewing caused recurrence of pain, he had for a long time been confined to his bed, principally on account of weakness. He was admitted to All Saints Hospital, of Kansas City, March 18, 1892. At that time the following entry was made: "Status præsens—Patient pale and anemic; emaciated; lines of pain upon face; heart, lungs and abdominal organs normal; no disease of ear, eye, nose or throat; no trouble in antrum (examination by electric light in mouth) nor alveolus to account for pain; while talking paroxysms came on—typical trigeminal tic. Put to bed and ordered forced feeding and

R Quinina hydrobromat . . . . . 1.5

Ferri sulphat. exsiccata . . . . . 1.

Hyoscyamina sulphat . . . . . .01

"Misce et ft. capsul No. xvi. Sig.: One every four hours."

There was no improvement under this, so far as concerned pain, but the general condition was slightly better on March 28. On March 29 I made Rose's operation, being assisted by Drs. J. D. Griffith and J. F. Binnie, of Kansas City. The third division of the nerve could not be found on cutting away the pterygoids, so the location of the foramen ovale was determined by comparison with the dry skull. The trephine was applied a little too far behind the foramen so that it cut into the foramen spinosum, wounding the middle meningeal artery; the bleeding was very severe for a moment, and it seemed as if the carotid would have to be tied, as has been advised for such an accident, but by persistence the vessel was secured; no further difficulty was experienced except that the patient seemed ready to die from a combination of weakness, anesthetic and shock; so the operation was hurried and completed in fifty-five minutes. An ideal convalescence followed. The shock was easily overcome; the temperature rose to 100.5 degrees on the day following operation, but rapidly declined—pure surgical fever; freedom from pain was complete; there was little nausea, and the appetite speedily improved. There was a gain of

ten pounds in weight in two weeks. The wound healed by primary union. He was discharged from the hospital April 12, 1892.

Here was a typical case for operation. And the result has justified the apparent severity of the remedy. For nearly three years have now passed since the operation, and there has been no return of the pain. The severe conjunctivitis which followed and which at one time I feared might destroy the eye finally disappeared, though for several months the eye had to be protected. Considerable difficulty in mastication was at first experienced from the stiffness of the jaw and from accumulation of food upon the insensitive side of the mouth, but the man finally learned to overcome this and at the present time has no trouble whatever.

Was the ganglion destroyed in this case, or was the good result due simply to cutting the nerve outside the skull? Senn and others have insisted that it is impossible to remove the ganglion by this route and that the benefits arise simply from division of the second and third branches of the fifth nerve during the attempts at removal. Whether it is taken away in its entirety or only partially destroyed, or whether it is not even touched during this operation, are questions of more theoretical than practical interest, so long as the results are as satisfactory as in this case: relief from pain which renders life a burden. But that cure depends not upon section of the nerve instead of removal of the ganglion is certainly to be inferred from comparison of the history just given with that of the following case:

Mrs. Jacob M., of Hope, Kan., I saw in consultation with Dr. J. N. Ketchersid on July 21, 1893, at her home. She was 48 years of age. Her general health and family history good. For four or five years there has been persistent severe neuralgia of unknown cause, which affected the third division of the fifth nerve. Several sections had given temporary relief—the last being of the nerve just as it enters the dental canal. For the past six weeks prior to my first visit almost intolerable pain had continued, morphin, etc., affording little relief. For five days she had not tasted food as every movement caused a return of the paroxysmal agonizing pain. With the assistance of Drs. Ketchersid and Miles, I began the Rose operation, but upon reaching the point of trephining the base of the skull my courage failed, for the operation was in a private house and the light not good. I therefore simply cut the nerve at its exit from the foramen and removed much of it, completing the operation in the usual manner. July 22 she was resting nicely without pain, and had slept all night for the first time in many months. July 25, Dr. K. wrote: "Patient's temperature this morning normal, pulse 85. She is doing well and gaining rapidly in strength." Convalescence was satisfactory in every detail. For a little more than one year there was complete relief from pain, but at the end of that time little twinges began to be noticed and these have gradually increased in severity until recently the paroxysms have assumed great intensity and the doctor has been in correspondence with me about removing the ganglion from above.

Dr. Frank Hartley, of New York, has described a modification of Horsley's operation, the steps consisting in reflecting the tissues (including the bone) over the temple, the base of the initial curved incision being over the zygoma and the flap reflected downward; the dura is gently pushed away from the bone by means of a spatula until the foramen rotundum and foramen ovale are exposed, without opening the dura except where it divides to inclose the ganglion. The nerve is then cut behind the ganglion and the latter torn from its depression with dissecting forceps from above. Theoretically and experimentally upon the cadaver this operation is a good one, and Dr. McLane Tiffany of Baltimore has operated successfully four times with good results; but I have the

same objections as to the Horsley method: too much brain compression and danger of hemorrhage. That these objections are not based upon visionary reasons is proved by the following case:

Mrs. W., 65 years of age, married, was operated on Oct. 23, 1893, by Dr. J. D. Griffith, of Kansas City, assisted by Dr. J. F. Binnie and myself. All went well until the attempt to raise the dura to expose the ganglion. Serious symptoms: depressed heart's action and irregular respiration then arose—necessitating repeated interruptions. Finally the petrous bone was well uncovered, but the bleeding was so excessive by the time the region of the ganglion was reached as to compel cessation of operation and the application of gauze pressure. After repeated efforts we were compelled to desist, tamponing the wound with iodoform gauze to prevent death from hemorrhage. Four days later the wound was unpacked and a second unsuccessful attempt made to remove the ganglion, during which the dura was penetrated. Again recourse to the gauze tampon was necessary to save life temporarily. The patient died three days later as a result of meningitis.

Now Dr. Griffith is one of the most careful surgeons in this country and I am sure no other operator could have accomplished what he failed to do in this particular case; and I feel equally certain that had the Rose method been adopted the ending might have been more favorable.

As a result of observation, therefore, as well as experimentation, I am compelled to say that the Rose operation for removal of the Gasserian ganglion appears to me to be the one easiest of execution and safest in practice.

## ORIGINAL ARTICLES.

### A REPORT OF FOUR ILLUSTRATIVE ABDOMINAL SECTIONS.

Read by title before the Southern Surgical and Gynecological Association, November, 1894.

BY L. S. McMURTRY, M.D.

PROFESSOR OF GYNECOLOGY IN THE HOSPITAL COLLEGE OF MEDICINE LOUISVILLE.

Clinical reports possess a peculiar value to practitioners of medicine as attesting the absolute results of treatment. The four cases here reported illustrate as many distinct and separate conditions of disease, in which none other than radical surgical treatment can avail. These cases occurred in my practice during one week; the four operations having been performed within six days. In all the cases the indications for operation were absolute and urgent; they passed into easy convalescence without untoward symptoms of any kind, and have made complete and perfect recovery. In Case 4 the operation was followed by pronounced shock, from which the patient rallied in a few hours. All are now in the enjoyment of perfect health three months after operation.

The object of this report is to illustrate the indications for operation in grave conditions of disease formerly imperfectly understood, and to demonstrate the safety of operative treatment, promptly and thoroughly applied. The profession has been slow to accept the practical truth that the risk of operating in such cases as I will report is incomparably less than that of temporizing by treating symptoms. Among the increased risks to life from delay, the feeble condition of the patient and the complications resulting from rapid tissue changes demand recognition. For convenience I will report the cases in reverse order, beginning with the last case of the group:

*Case 1.—Extra-Uterine Pregnancy; Rupture, Hemorrhage and Shock.* Mrs. D., aged 25, on the evening of September 23, while undressing to retire, was attacked by sudden pain in the left iliac region. It did not last long and was relieved by rest and warm applications. This lady had been married six years, and about two years since suffered a miscarriage with considerable hemorrhage; since that time she had complained of pelvic pain and menstrual irregularity. At the time mentioned she had missed two menstrual periods. On the Wednesday night following she was attacked with violent pain in the same region, much more violent than before, and was given a full dose of morphia hypodermically which gave her some relief. On the following morning she got up to empty the bladder and while doing so fainted, became deathly pale and cold and was seized with nausea and vomiting. The pain was intense and for several hours she exhibited the symptoms of profound shock and internal hemorrhage—pallor, bloodless lips, surface cold, and pulse rapid, small and feeble. Under the influence of stimulants freely administered, hot applications to extremities, mustard to epigastrium, and atropia hypodermically, she gradually rallied late in the afternoon. On the following day her abdomen was swollen and tympanitic, and very sensitive to the touch. Three days afterward she passed a perfect cast of the uterine cavity. Her pulse ranged about 120, and she had an evening temperature of 101.

This description of her symptoms is a literal extract from a letter written me at the time by her father, himself an experienced practitioner of medicine. Three days later her father wrote that her symptoms were materially improved. The pulse had fallen to about 100, the temperature had come down to normal and her condition was better in every respect. Still the abdomen was considerably swollen and quite tender in the left iliac region. There was a slight bloody flow from the uterus. These symptoms it will be observed, correspond with the shutting off of the area of rupture and hemorrhage from the general peritoneum, with arrest of bleeding temporarily by blood clot. On Thursday, October 11, she was transported in a carriage to the railroad station, placed in a sleeping car, and brought to the Jennie Casseday Infirmary for Women in Louisville. She bore the journey well, and reached the infirmary without aggravation of symptoms. She was accompanied by her father and husband, both of whom are physicians. An examination of the pelvis demonstrated that the cavity was choked with effusion. The uterus was pushed to the right, and Douglas' pouch and the left lateral space packed.

Saturday morning, October 13, I opened the abdomen and found the pelvic peritoneum filled with blood clot, which was breaking down; peritonitis was active and progressive. After removing two or three pints of blood clot, I brought up into the incision the left uterine appendage, and tied it off close to the uterus. The point where the tube ruptured is very plainly seen. An examination of the uterine appendage on the opposite side demonstrated the existence of chronic salpingitis with adhesions and occlusion of the tube, evidently the result of long standing chronic inflammation. It was removed. The peritoneal cavity was flushed with several gallons of warm distilled water, a drainage tube placed, the incision closed, and the patient returned to bed. Her convalescence was uninterrupted. Her pulse remained under 100; she suffered no pain; the abdomen remained flat; the bowels were moved on the third day in response to an enema; the drainage ceased by the third day; the tube was removed, and convalescence was established without any interruption whatever. She returned home quite well at the end of the fourth week. Drs. Coleman Rogers, Mandeville Thum; and Robert Stuart were present at the operation.

*Case 2.—Chole-Lithiasis; Impaction of Cystic Duct; Cholecystotomy.* Mrs. B., of Uniontown, Ky., was brought to me by Dr. Norman, a well-known physician of that place, on Wednesday, Oct. 10, 1894. She is 52 years of age, of vigorous constitution, and until three years ago enjoyed uniformly good health. For three years past she has suffered with frequent violent paroxysms of abdominal pain, only imperfectly relieved by large doses of opiates. Her digestion was impaired, she was several times jaundiced, and for several months past her suffering was almost constant. She had been treated by different physicians for various supposed conditions of disease. Dr. Norman some months ago detected a globular tumor in the right hypochondrium which had enlarged steadily. An examination of the tumor gave conclusive evidence that it was an enlarged gall bladder, and with associated history justified a diagnosis of gall stones, most probably impacted in the cystic or common duct.

Thursday morning, October 11, the day after the patient's arrival at the infirmary, I did cholecystotomy. A vertical incision about three and a half inches long was made immediately over the tumor; firm adhesions were encountered all about the distended gall bladder. These were carefully separated and the gall bladder brought up into the incision. A flat sponge was packed underneath so as to protect the

peritoneum and the gall bladder instead. The gall bladder was filled by a perfectly clear fluid, a mucoid secretion characterizing this form of biliary obstruction. After emptying this, my finger detected a large stone firmly impacted deep in the cystic duct. I experienced considerable difficulty in removing it. It is well known that the walls of the gall bladder and its ducts are thin and friable, and hence the utmost delicacy of manipulation must be observed when the duct is stretched by an impacted stone. It is very easy to push it through the thin tissue of the duct. Various forceps have been invented for the removal of stones under these circumstances, some with padded blades for crushing the stone from the outside of the duct. With two fingers introduced within the abdomen and the index finger of the other hand within the gall bladder, I succeeded in dislodging this large stone without injury to the duct, and removed it.

The further steps of the operation consisted in sewing the incised gall bladder to the parietal peritoneum of the incision, introducing a rubber tube into the gall bladder, and closing the incision, (except at the central point where the tube was placed) in the usual manner. In this way the gall bladder is drained through the abdominal wall. Before the operation was concluded bile began pouring out through the gall bladder. The patient's convalescence was smooth and uninterrupted, being entirely afebrile and requiring no opium or other anodyne. The tube remained in the gall bladder until the discharge ceased and the bile followed the normal channel. The opening closed altogether during the fifth week. The patient was entirely and immediately relieved of pain and is now quite restored to vigorous health.

*Case 3.—Suppurative Salpingitis and Peritonitis.*—L. J., age 25, referred by Dr. P. F. Barbour, had suffered for several months from pelvic inflammation. The history and symptoms leave no doubt as to the infection being due to gonorrhea. For seven weeks prior to admission to the infirmary she was very ill with peritonitis. The abdomen was tender and tympanitic, pulse rapid and temperature ranging from 101 to 104 degrees F. The suppurative stage was marked by rigors and profuse sweating. Pain was paroxysmal and so severe that morphia was daily and freely used.

An examination revealed the characteristic symptoms of suppurative salpingitis and pelvic peritonitis. After free purgation, abdominal section was done October 9. The pelvic viscera were matted down with adhesive exudate, which being separated allowed pus to flow out of the incision. The Fallopian tubes were distended with pus, the left having ruptured. The tubes were glued to the ovary on each side and both ovaries had been converted into abscess sacs. The specimens illustrate the extreme ravages of specific suppurative salpingitis and ovariitis. After thorough enucleation the rotten appendages were tied off close to the uterus. The peritoneum was flushed freely with warm water, a glass drainage tube placed, and the incision closed. The progress of the case was uninterrupted, and convalescence was prompt. Neither morphia or other opiates were given during convalescence. At the expiration of the third week the patient went to the country and writes that she is quite well. Drs. Barbour and Rogers, of this city, and Drs. Stuart and Dunn of Henderson, were present at the operation.

*Case 4.—Post-puerperal Pelvic Inflammation, with Suppuration.*—Age of patient 21 years; confined July 26, 1894, and during convalescence developed peritonitis. After an acute illness of several weeks, during which time she exhibited the symptoms of puerperal peritonitis, the inflammatory process seemed to abate and her condition was hopeful. During the latter part of August her condition was complicated by abscess of the breast, which required incision and gave much distress, at the same time adding to the exhaustion of an already enfeebled condition. I saw the patient in the latter part of September in consultation with the family physician, Dr. Coleman Rogers. For several weeks preceding the condition was one of seeming improvement with recurrent attacks of violent pain necessitating repeated doses of morphia, accompanied with fever and sweats. These exacerbations undoubtedly marked the invasion of additional areas of peritoneum by the inflammatory process. Dr. Rogers had utilized purgatives, as well as all other non-surgical resources in the treatment, and requested a consultation with a view to operative interference. An examination disclosed the most extreme and advanced lesions of post-puerperal pelvic inflammation. The uterus was bound down upon the floor of the pelvis, the fundus in Douglas' pouch, and the rectum almost occluded by its pressure. All the pelvic viscera were fixed, being bound by extensive deposits of organized exudate. There was an indistinct sense of fluctuation in the lateral pelvic spaces when the bimanual touch was applied. The patient was pale, feeble and emacia-

ted, racked with daily exacerbations of pain and constant fever.

On Oct. 6, 1894, during the eleventh week of illness, the patient was removed to the infirmary and on the following morning abdominal section was made. Ether was very cautiously given, and the operation performed as quickly as thorough and careful work would permit. On opening the abdomen (suprapubic) the omentum was found agglutinated to the intestines, roofing in the pelvic viscera. Releasing this and working a track of cleavage with two fingers through the coils of intestines the pus freely poured out of the incision. In separating the adhesions at the floor of the pelvis, and enucleating the disintegrated tubes and ovaries (applying only gentle force cautiously), my index finger penetrated the uterus. Recognizing this, I forcibly released that organ (observing the utmost care not to open the rectum to which it was adherent), and brought it up with the suppurating appendages. The body of the uterus was friable, breaking down under slight force; the appendages were mere abscess sacs. Having separated adhesions so as to release the intestines, I threw a small wire attached to Kœberle's nœud around the cervix uteri, and removed the uterus and appendages. The peritoneum was thoroughly doused with several gallons of warm water, a drainage tube placed, and the incision rapidly closed. The operation was completed in thirty-two minutes. Dr. Guest, the anæsthetist, had already administered stimulants hypodermically. The patient was put to bed without any pulse that we could detect in the wrist, though the heart was acting with great rapidity. The usual stimulants subcutaneously, with dry heat to the surface and extremities, were persistently applied, and the patient gradually rallied. The pulse was rapid and small for three days, then gradually improved. The drainage tube was removed on third day, the nœud came away on the eleventh day, and healing was prompt and complete. The patient rapidly gained strength and flesh, and is now a perfect picture of health. Dr. Coleman Rogers and Dr. T. P. Satterwhite were present at the operation.

### THE OPEN AIR TREATMENT OF CONSUMPTIVES WHO CAN NOT SEEK CHANGE OF CLIMATE.

Read at the meeting of the "Tri-State" Medical Society at St. Louis.  
April 2, 1895.

BY ROBERT H. BABCOCK, A.M., M.D.

PROFESSOR OF CLINICAL MEDICINE AND DISEASES OF THE CHEST, COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO; ATTENDING PHYSICIAN, COOK COUNTY HOSPITAL.

The importance of climatotherapy in the treatment of consumption was recognized even by the ancients. As long ago as the time of Hippocrates and his immediate successors it was held that consumptives should be removed to a distance from the locality in which they had contracted their disease. From that day to this, physicians have been in the habit of ordering change of climate for their phthisical patients in the belief that in a judicious and early employment of climatotherapy lies the consumptive's best hope of recovery. Much thought and investigation have been given to the determination of those qualities of climate to which its remedial virtues may be attributed. These would seem to be dryness, high altitude, equability and purity. Yet that dryness and high elevation are not fundamental requirements for

all cases, is shown by the fact that some patients do well in sea stations such as the Island of Madeira. Equability of temperature can not always be relied on at resorts of greatest repute, such as those of mountain climates. The one quality common to all well known and justly celebrated resorts is purity of the atmosphere, and when combined with dryness and low atmospheric pressure, of mountain resorts, we have those qualities most conducive to recovery from pulmonary tuberculosis. Nevertheless, some patients recover who never seek a high altitude; others, who never leave home. And those who seek the most favorable climate possible receive little or no benefit unless they remain out of doors a large proportion of the time. Furthermore, Dettweiler, from his Sanitarium at Falkenstein, Germany, reports from 24.5 to 27 per cent. of recoveries of patients in all stages. And yet his institution is located in the cool, damp, changeable climate of Germany in the Rhine country. Similar results are achieved at Bremer's Sanitarium in the equally unfavorable climate of Görbersdorf, North Germany. Surely then, there must be something more than mere removal to a favorable climate if the consumptive would recover, and on the other hand there may be some hope for the consumptive who can not seek change of climate. This condition upon which depends the welfare of the phthisical patient, whether at home or at a health resort, is life in the open air.

Consumption may be said to be the disease of indoor life. Its victims are those forced by occupation or circumstances to spend their days within four walls. It rarely attacks persons who work in the open air, unless their health be undermined by vicious habits or conditions of environment that antagonize the beneficial effect of their outdoor life. While penning the foregoing sentences I was consulted by a lady of tubercular family history, who had developed pulmonary disease within a few weeks previous, largely I believe in consequence of having exchanged residence in South Dakota with much time spent out of doors, for the opposite conditions of life in Chicago. Such facts are so numerous as to point unmistakably to the disastrous consequences of indoor confinement. Why then should this, Nature's remedy, fresh air, be withheld from individuals already suffering from pulmonary tuberculosis? And yet this is precisely what is done in only too many instances.

Last fall I was consulted by a young lady with pronounced pulmonary tuberculosis, whose physician had warned her against going out doors, lest she should take cold. It is not at all uncommon to find the consumptive in an advanced stage with all the phenomena of sepsis, lying in an overheated, ill-ventilated apartment from which he is never moved.

Therefore I desire to lay down two following propositions: 1, a consumptive who can not seek change of climate should pass his days in the open air, no matter what the stage of his disease; 2, under proper precautions this may be done in all weathers, excepting the severe cold of winter, when the thermometer registers below 15 degrees above zero.

And now I propose to devote the remainder of this paper to the description of how and why this should be done.

In the summer of 1893 it was my good fortune to be able to visit Dettweiler's famous Sanitarium at Falkenstein, where the open air treatment of consumptives is carried out in its perfection and with truly brilliant

results. The institution is situated at the altitude of about one thousand three hundred and fifty feet above the sea, and is protected from cold northerly winds by the low Taurus Mountains, among which it lies. It is constructed around three sides of a square, so that its galleries face the southeast, and obtain all the sunshine possible. In these open galleries, protected from the elements only by canvas curtains, the patients spend the entire day from eight to ten hours, reclining in easy chairs or on couches and covered by sufficient rugs to withstand the cold. This open air treatment is so generally employed, that according to Dettweiler's figures all but  $8\frac{1}{2}$  to  $9\frac{1}{3}$  per cent. of the patients were submitted to it, winter and summer, during the year in which his statistics were collected. The patients are taken into the fresh air about 11 o'clock A.M., after they have had their breakfast and as a rule are not brought in again until 9 or 10 o'clock in the evening. Their meals are served out of doors and they while away their time by conversation, reading, playing games, etc. The range of winter temperature during which Dettweiler reports this treatment as carried out was between 12 and 41 degrees above zero, F., and it was not deviated from because of rain, wind or snow, since the patients could be sufficiently protected by the canvas curtains. Very feeble patients are taken out and kept in their beds, those suffering from high fever are kept in the open air until daily defervescence sets in, when they are returned to their rooms. The small percentage of those not subjected to this treatment are invalids suffering temporarily from complications.

Marked benefit is said to be observed, such as diminution of fever, cough and expectoration, cessation of sweating, lessened nervousness, return of appetite and digestion, and gain in strength and weight. Physical rest in the open air in the manner described is insisted upon so long as patients have marked fever and wasting. When sufficiently improved, they are allowed to take exercise cautiously, walking at first but five minutes at a time; the amount of exercise permitted being gauged by the effects. If rise of temperature result, no matter how brief the exercise, they are again subjected to rest. The most careful attention is paid to diet, and in all respects they are managed in accordance with the most approved principles of clinical and symptomatic treatment and individual peculiarities.

Certain precautions are necessary in subjecting a consumptive patient to a mode of treatment not only vigorous but at the same time wholly at variance with what he has been accustomed to. He is notoriously sensitive to cold, partly in consequence of anemia, perhaps, but largely because of exaggerated reflex sensibility on the part of the nervous system. The moment a breath of cold air strikes his body, reflex contraction of the cutaneous vessels takes place and he complains of chilliness. This is intensified by his fear of cold air, which makes him shun exposure and prefer a temperature of enervating warmth. Indeed, his sensitiveness to drafts is so exaggerated, that as Dettweiler observes, he may be said "to have a disease of the skin as well as of the lungs." Nevertheless, inasmuch as the *pars minoris resistentiæ* is the pulmonary mucous membrane, a chill may at any time result in congestion if not actual inflammation of the lower respiratory tract. Consequently if a patient is to be subjected to this open air

treatment, he must undergo a hardening process to deprive him of his abnormal sensitiveness; that is, he must be gradually accustomed to cool air and drafts without feeling cold. This may be done by friction of the surface, movements of the body and the adjustment of additional clothing. The patient must be exposed to cool air until he begins to experience a sense of slight chilliness, when an attendant must at once begin to rub him briskly to anticipate and prevent its intensification into a pronounced rigor. Sometimes it may suffice to shift about on the couch and move the extremities, or for the attendant to cover him up more warmly with additional wraps. Furthermore, such a sensitive patient should not be taken out of doors in the early morning hours at a time when chills are most easily induced, but toward noon, say 11 o'clock, after he has had his breakfast and the body temperature has begun its diurnal rise. If in spite of these measures a chill and consequent bronchial congestion or inflammation result, the patient must be at once taken to his room and there subjected to a reactionary or revulsive treatment. This consists of dry friction underneath the clothing in such a way as not to subject the patient to still further exposure. Hot drinks should be given, counter irritation applied to the chest and the rubbing continued until the surface is in a vigorous glow. Then if fever comes on with other symptoms pointing to the patient's having taken cold, in spite of the measures to ward it off, he should be confined to his room until all active symptoms abate. He may then again be taken into the open air and be put through the former régime. As a consumptive improves in strength and endurance he may be subjected to morning sponge baths with cool water or diluted alcohol, followed by vigorous friction, and thus gradually become prepared for even so energetic a measure as the cold douche or shower bath. His sleeping apartment should be kept thoroughly aired while the invalid is out of doors, and fresh air in abundance should be admitted, even at night, through an open window either in the same or an adjoining chamber.

Such is the outline of the treatment advocated for consumptives not permitted by circumstances to seek a change of climate. It only remains to describe briefly a practicable method which the general practitioner can carry out in the case of a private patient. In the country or in a town, the air of which is not contaminated by dust and smoke as in a large city, a piazza, so situated as to get the sun, can be utilized for the purpose. By means of canvas curtains or screens the invalid's couch can be sheltered from rough winds and storms. If there be not a convenient veranda, a tent can be pitched or a rough shed built at the side of the house, least exposed to assaults from the weather. In case the consumptive be too feeble to be actually taken out of doors he may occupy a sunny room, whose windows are kept wide open. During the coldest days of winter the temperature of the apartment may be moderated by artificial heat. An open grate fire is the best, but even furnace or stove heat will answer if free from coal gas. A patient in the early stage may be permitted as much exercise in the carriage, in saddle or on foot as he can take without fatigue or rise of temperature. This latter is a most important point and his temperature should be carefully taken and registered both before and after exercise. If even slight fever result, the consumptive should be compelled to

rest in the open air so long as physical effort is found to induce rise of the body heat. An attendant should be provided and instructed to carefully guard her charge against chilling in the manner previously described. A trained nurse would be perhaps the best, but an intelligent member of the family can be instructed in the duties of the position. But this is not all; the patient himself will generally require mental as well as physical treatment. He must be made to understand the necessity of the baths, frictions and douches calculated to harden his skin, also why rest, instead of exercise may be required, and he must be taught not to expect striking results at first. The consumptive is either apt to be easily discouraged if he does not perceive immediate results, or on the other hand to fail of appreciating the importance of, to him, trifling details in the carrying out of a prescribed régime. If the precautions are well observed, the treatment should be carried out rigorously to the extent of even the meals being taken out of doors. In many instances no doubt the prejudice of relatives and friends will have to be overcome, requiring intelligent explanation of the advantages and benefits to be expected. Even in large cities, where a suitable piazza or yard space is not available a measure of the treatment can be carried out in some room selected for the purpose. "Half a loaf is better than no loaf," and if the physician can not secure everything desirable in this mode of climato-therapy, he may yet improve on the overheated, ill-ventilated atmosphere in which so many hectic patients are consumed. There is nothing in this plan that militates against other rational means of treatment. In fact, everything medicinal, dietetic and hygienic, conducive to recovery, should be utilized. Symptoms will not disappear at once or even rapidly, but most of them particularly the fever will be favorably influenced. If the invalid continues to perspire freely his nurse should dry him by prolonged friction under the clothing. His appetite should be encouraged and his dietary carefully supervised each day. Consumption is a mixed process; destruction of pulmonary tissue on the one hand with the phenomena of septic infection on the other. There is consequently abnormal metabolism of tissue, calling for greater intake of oxygen, yet there is deficient lung capacity to meet the demand for increased oxydation and hematosi. Is it not rational therefore that the consumptive be placed in such an environment, as will best fulfill the needs of his organism? The statistics at Falkenstein and Görbersdorf furnish the answer.

# A CASE OF OBSTRUCTION OF THE BOWEL FOUR DAYS AFTER ABDOMINAL SEC- TION—SECONDARY OPERATION— RECOVERY.

REMARKS ON PERITONEAL ADHESIONS.

BY FRANK C. FERGUSON, M.D.

Superintendent of the Indianapolis Sanatorium for Diseases of Women;  
Member of the Marion County Medical Society, the Indiana State  
Medical Society and of the AMERICAN MEDICAL ASSOCIATION;  
Formerly Editor of the Indiana Medical Journal, and Pro-  
fessor of Obstetrics, Central College of Physicians  
and Surgeons.

INDIANAPOLIS, IND.

Mrs. G., age 37, living in Huntington, Ind., was brought to my Sanatorium by her physician, Dr. Charles W. Wright, Feb. 15, 1895. She was the mother of two children, aged re-

spectively 13 and 6 years. Had been an invalid since the birth of the younger child. She complained of backache, headache, pelvic pain, indigestion, leucorrhea, dysmenorrhea and insomnia. Her appetite was good, but on account of gastric irritability she could rarely consume a good meal. She was emaciated and extremely nervous. Bowels constipated, vesical irritability.

Pelvic examination discovered a sharply retroflexed uterus bound down by adhesions; and an enlarged prolapsed ovary, pressure upon which elicited exquisite pain. Measurement of the uterus showed a longitudinal diameter of three and one-half inches. After one week's preparatory treatment, abdominal section, with the assistance of Drs. F. B. Wynn, Martha J. Smith and S. E. Crose, was made Feb. 22, 1895. The right ovary was adherent to a coil of intestine, three times its normal size, chronically inflamed, and a number of cysts were scattered over its surface. The corresponding tube enlarged and inflamed. Left ovary and tube healthy in appearance.

The adhesion between the ovary and intestine was carefully separated, a ligature of chromicized catgut adjusted as closely as possible to the cornu of the uterus, and ovary and tube severed with the thermocautery. The stump was thoroughly charred with the cautery and dropped. The uterus was then brought forward, after separating the adhesions, and sutured to the abdominal wall, after Pozzi's method. The incision was closed by six silkworm gut sutures. The operation was completed within a half-hour and the patient put to bed in good condition.

The progress of the case was satisfactory in all respects until the following Sunday evening, (four days after the operation) when symptoms of intestinal obstruction made their appearance. The patient vomited several times and had paroxysmal pain in the right ovarian region. Several efforts which failed, were made during the night to procure an evacuation from the bowels by rectal injections. On Monday morning the patient expressed herself as feeling better and took some nourishment which she retained; pulse 120; temperature 99.5 degrees F. There was tenderness upon pressure over the right ovarian region, but no tympanites or tenderness of the abdomen. During the day a saline cathartic was given, followed by rectal injection, but no movement was secured. In the evening, nausea and vomiting again supervened, paroxysmal pain increased, which was relieved with morphia hypodermatically; the pulse mounted to 140, temperature 103 degrees F., and the abdomen became rapidly tympanitic. During the night she was given 10 grains of calomel in divided doses and three doses of Rochelle salts which she retained. This was followed in the early morning with high rectal injections, but the bowels obstinately refused to respond.

Condition Tuesday morning at 10 o'clock. Temperature 99.5, pulse 140; abdomen greatly distended and interfering with breathing. She is very weak but has not that haggard expression of countenance invariably noticed in peritonitis; still complains of colicky pain in the right ovarian region. Inspection of the abdomen revealed several coils of the small intestine in active vermicular motion, which convinced me that I had been in error in attributing the obstruction to paresis of the bowel. It evidently arose from adhesion, most probably between the stump and intestine.

During the day she was given, hypodermatically, every three hours, 1-30 grain strychnin and 1-100 gr. digitalin. A rectal tube was passed several times as far as the hepatic flexure of the colon, and injections given of turpentine emulsion, hot water

and milk of assafetida, with no result, except a passage of flatus when the fluid was expelled. In the afternoon I called Dr Dunning in consultation. Her condition had been steadily growing worse during the day. We agreed that peritonitis did not exist, that the bowel was obstructed from adhesions and that a secondary operation afforded the only hope of saving her life. I had telegraphed for the husband on the previous night and was anxiously expecting him in the early afternoon, as I did not like to reopen the abdomen without his consent, and yet time was precious. He was late in his arrival, but after explaining matters to him he consented that I might do anything that in our judgment was necessary. At 7 P.M., assisted by Drs. L. H. Dunning, Martha J. Smith and Frank B. Wynn, who kindly gave the anesthetic, I reopened the abdomen by rapidly severing the sutures with scissors and pressing the wound apart with my fingers. A coil of intestine was found adherent to the ovarian stump, bending it to a sharp angle, thus completely obstructing the bowel. The peritoneum was normal; the fundus uteri well up against the abdominal wall. After liberating the intestine and flushing the peritoneal cavity with hot aseptic water, a quantity of which was allowed to remain, a strip of iodoform gauze drainage was passed down and made to cover the stump, in order to prevent a recurrence of the accident. The fundus uteri was again sutured to the abdominal wall and the wound closed with silkworm gut sutures. A pad of iodoform gauze covered with a thick layer of absorbent cotton and a bandage completed the peritoneal toilet, and the patient was placed in bed. Pulse 150; temperature 100 degrees F. In the course of an hour she rallied from the anesthetic, but was so exhausted that she could not speak above a whisper. Nausea, vomiting and pain, however, had disappeared. During the night she received three rectal injections of milk and whisky, which she retained, and three hypodermic injections of 1-30 gr. of strychnin and 1-50 digitalin and several hypodermics of 1-100 gr. nitro-glycerin, when unusual depression was noticed.

At 8 A.M. Wednesday morning she suddenly went into collapse; pulse disappeared, and respiration declined to four or five per minute. I thought she was dying and called the husband. An injection of 1-50 grain nitro-glycerin, however, soon brought up the pulse and she again became conscious. Pulse 180. Throughout the day and during the night, these periods of extreme depression reappeared every hour or two, requiring the utmost vigilance upon the part of both nurse and physician.

It is unnecessary to go further into the details of symptoms and treatment; suffice it to say that twenty-four hours after the operation her bowels moved copiously; very slowly she came out of the awful depression which every moment threatened her life, and at this writing, one week after the secondary operation, she has passed the danger line, and I am sure will make a rapid convalescence.<sup>1</sup>

How to prevent peritoneal adhesions after abdominal section is, perhaps, the most important problem that now confronts the abdominal surgeon. The technique of intra-abdominal surgery, so far as the removal of abdominal growths, diseased organs and tissues is concerned, has been brought to such perfection that little remains to be done; and it is doubt-

ful if any further improvements in this direction will be of much utility. But no safe and expeditious method has yet been devised for the prevention of peritoneal adhesions—the constant dread of the surgeon and a standing menace to the life, health and comfort of the patient.

\*While it is true that plastic surgery will contribute much, in some cases, to the prevention of post-operative adhesions, yet it is oftentimes practically impossible to cover all injured surfaces with healthy peritoneum, both on account of the difficulty in finding them, and because the length of time consumed in plastic work is more dangerous to the life of the patient than the risk of adhesions. The Trendelenburg position enables the operator to discover peritoneal traumata which, otherwise, would not be found; nevertheless the greatly increased dangers to the patient from prolonged anesthesia and long continued exposure of the peritoneum, will, in many cases, overbalance any advantages that accrue from plastic work.

I think it is generally admitted by abdominal surgeons that, other things being equal, the sooner an operation can be completed and the abdomen closed the less danger there is to the life of the patient. Dr. Alex. J. C. Skene, in an able article contributed to the *Brooklyn Medical Journal* (February, 1895) entitled, "Defects in Surgery as taught and practiced at the present Time," calls especial attention to prolonged anesthesia and slow operating as fruitful causes of death after surgical operations. "Rapid operating," he says, "is essential and imperative. Every moment wasted in an operation is a detriment to the patient as well as the surgeon. Operations that are quite well done are done quickly, as a rule. Slow operating is generally imperfect. It is often said that a quarter of an hour, more or less, in the duration of an operation makes very little difference. This I conceive to be a very great error. . . . Rapidity of operation is especially necessary in order to avoid prolonged anesthesia. All anesthetics are injurious, and tend to retard recovery from operations and impair the health of patients subsequently. The longer one is kept in a state of anesthesia, the more harm is done. . . . Again, time is precious, because the longer the tissues are exposed and the more they are handled, the more slowly and imperfectly they heal. Tissues exposed to the air for an hour or more, begin preparation for healing by granulation and are, therefore, less capable of uniting by immediate union. . . . Especially are non-union, supuration and sepsis likely to follow if the patient has been intoxicated for a long time by the use of the anesthetic; and unfortunately, prolonged anesthesia and unnecessary injury of tissues usually come together."

I do not quote the above as an argument against plastic surgery of the peritoneum whenever it can be done quickly and with safety to the patient. But in all cases where we have reason to believe that the time consumed in such work will endanger life, some other means should be adopted to minimize the danger of post-operative adhesions, and the abdomen closed as quickly as possible. A living patient with intra-peritoneal adhesions is much more to be admired and is a far better advertisement for the surgeon than a dead or dying one whose interior has been ever so artistically decorated with plastic surgery.

Are there any expeditious and efficient measures

<sup>1</sup> March 30, 1895. The patient has completely recovered. The uterus is in normal position and all symptoms of pelvic disease have disappeared.

which can be used to prevent post-operative adhesions? Several plans have been proposed by authors, but the limits of this paper will not permit their enumeration. I shall, therefore, speak of but two; those which from personal experience I believe will give the best results, viz., flushing the abdominal cavity with aseptic water, and frequent changes in the posture of the patient.

Malcolm, of London, in 1891 first directed attention to a mode in which washing out the peritoneal cavity might act beneficially in the prevention of adhesions. (*Annual of the Universal Medical Sciences*, 1891, vol. III): "It affords," he says, "an important means for promoting a natural adjustment of the intestines. If in completing the process of washing, the abdominal cavity be distended with fluid, the intestines must be floated up toward the highest circle of the cavity, thus facilitating changes in the relative positions of the various coils and straightening out the mesentery, undoing acute twists and throwing it and the bowels into natural folds. If the fluid is then permitted to flow out or carefully sucked out of the pelvis by means of a tube, the intestines will tend to settle down in a natural position. Adhesions, when the intestines are in normal position, do not produce obstruction."

My own personal experience has convinced me of the great utility of this method. I do not, however, permit the fluid to escape from the abdominal cavity, but leave it there to be slowly absorbed. It can do no possible harm and I believe that it contributes no little to the prevention of adhesions by permitting the intestines to glide freely upon each other so long as the fluid remains in the cavity, thus forestalling adhesions in their incipency.

The next measure for preventing adhesions, which admirably supplements the preceding, is a frequent change of the posture of the patient. I was led to adopt this plan from the observations of Dr. Malcolm, that patients who suffer much after abdominal section from vomiting caused by the anesthetic, not infrequently recover more satisfactorily and more promptly than those who are not so affected. His explanation is, that the retching and straining in the efforts at vomiting have a tendency to restore to a natural position the displaced intestines before adhesions form or become firm. This explanation, in my opinion, does not go far enough, for it is quite probable that the churning of the intestines by the diaphragm and abdominal muscles, during the act of vomiting, is a potent factor in the actual prevention of adhesions, as well as tending to restore the intestines to normal position.

During the last three years I have adopted these methods in several cases of abdominal section for pyosalpinx in which the adhesions were of such nature that a differentiation of tube, ovary and intestine was wellnigh impossible. The adhesions were broken up and ovaries and tubes removed with much difficulty. The patients recovered promptly and have been, up to date, free from pelvic pain, neither have they had at any time other symptoms of adhesions. I can not say that adhesions do not exist in these cases, but if they do they are so benign in character that they produce no inconvenience.

I did not flush the pelvic cavity with aseptic water in the case reported, because there seemed no necessity for doing so. The operation was done aseptically; it was almost bloodless, and but a few drops

of blood, if any, escaped into the peritoneal cavity; the traumatism inflicted upon the peritoneum was very slight, indeed, and yet within four days it became necessary to reopen the abdomen to save the life of the patient. I am firmly of the opinion that had I flushed the pelvic cavity with aseptic water and closed it while full of the fluid the accident would not have occurred.

There are two other points in the case of great interest, viz., the extreme rapidity of the pulse for four or five days succeeding the second operation, and the large amount of strychnia given hypodermatically. During the first twenty-four hours succeeding the operation the pulse did not fall below 160, and frequently ran to 180. During the second day it ran from 150 to 160; third day from 140 to 160; fourth day from 130 to 150; fifth day from 120 to 140; sixth day from 110 to 120. On the seventh day it declined to 100. The temperature ran from 99.5 to 103 F. During the twenty-four hours preceding the operation, the patient was given hypodermatically, every four hours, 1-30 gr. strychnia and 1-100 gr. digitalin. The first twenty-four hours succeeding the operation she received every four hours the same quantity of strychnia and digitalin, and some six hypodermics of 1-100 to 1-50 gr. nitro-glycerin. The third day she received, every four hours, the same quantity of strychnia and digitalin; the fourth day the same doses every six hours; the fifth day three doses. It was not until the fourth day that I perceived any distinct symptoms of the physiologic action of the drug.

The case is a very instructive one and teaches two or three valuable lessons, viz:

1. That serious obstruction of the bowel may arise from an insignificant wound of the peritoneum.

2. That perseverance in judicious therapy may sometimes save life, even when the case seems absolutely hopeless.

3. It emphasizes the necessity, in such cases, for prompt surgical interference. Had we deferred the operation in the case reported, a few hours longer, a valuable life would have been sacrificed.

In conclusion, I wish to express my grateful acknowledgments to Drs. L. H. Dunning, Frank B. Wynn and Martha J. Smith, to whose wise counsel and efficient assistance I am indebted in a great measure for the successful issue of the case.

208 N. Alabama Street.

## VAGINAL OÖPHORECTOMY.

BY C. P. THOMAS, M.D.

EVERETT, WASHINGTON.

It has been very evident to the writer, for the past two years, that celiotomy for the removal of small, cystic, prolapsed, painful or adherent ovaries, or small tubal cysts or pus tubes, even by those who have done the greatest number of these operations, is fast falling into disrepute.

Many of our leading gynecologists are curetting, or packing the uterus, or attempting to catheterize the Fallopian tubes, with the vain hope of avoiding the necessity of opening the abdominal cavity for their removal in the usual way.

At least two of our latest works on gynecology recommend that curettage be tried for pus tubes, and if that fails, give rest and expectant treatment, with

general tonics, and the pus will often disappear by absorption, or through inspissation.

The same writer admits, however, that single pus tubes are more dangerous than double ones, owing to the liability to accident should the woman become pregnant, and it is in such cases that the operation I here advocate will be especially applicable.

The accidents incident to making and closing the abdominal incision are so well known to every operator that I will not dwell upon them, also the unfavorable sequelæ, such as hernia, stitch abscess, and last but not least adhesions, not alone of the omentum but also of the intestine, producing colic, pain, and even strangulation.

These and many more are the reasons why the abdominal method of removing small cystic, prolapsed or adherent tubes or ovaries should be abandoned for the vaginal method. By removing them through a small incision in the posterior cul-de-sac, where ample room is provided for the operation, in the hands of any one competent to do major gynecologic surgery, it is a safe, simple procedure, free from the dangers just enumerated. Should the operation be undertaken and a tumor found to be too large or adherent to be completely removed in this way, the operator can then resort to the abdominal method, and the opening in the vagina will do no harm and may perchance do good by affording perfect drainage.

I also believe that this is a valuable form of drainage and should be resorted to often, when a drain is required following abdominal section.

The steps of the operation are as follows: With the patient in the extreme dorsal position, held by a Clover's crutch, the vagina and external genitals are thoroughly cleansed with soap and water, bichlorid and alcohol. The posterior vaginal retractor being introduced (the self-retaining one of Dr. Beach, of Chicago, being the best I have used), the posterior lip of the cervix is caught by a vulsellum forceps, the uterus curetted, and irrigated if necessary. The cervix is then drawn forward and upward, and with a flat curved pair of scissors the posterior vaginal mucous membrane where it joins the cervix is clipped and with closed scissors or the finger it is stripped back from the cervix to the peritoneum, which is caught with a catch-tooth forcep, and an opening made large enough to admit a finger. The incision may then be enlarged laterally at will, provided you do not cut up, on either side to the uterine arteries or down to the rectum.

There is no bleeding of importance and with two fingers of one hand, then the other, the ovaries and tubes can be examined and adhesions, if not too strong, broken. They are then easily drawn down into the vagina, caught with a strong pair of forceps, the pedicle ligated, severed, and stump returned.

In one instance where I was required to operate quickly, I clamped the stump with pressure forceps, removed both tubes and ovaries, leaving the forceps in position for thirty-six hours. The vaginal opening was left for nature to close, which it did, in a few days, the patient leaving the hospital well in three weeks.

If there have been many adhesions broken, or a pus cavity opened, the vaginal wound should be packed with a strip of iodoform gauze; if not, it should be closed with one or two stitches of silkworm gut, passed through the mucous membrane and peritoneum, and fastened with the shot and coil.

The time required for the operation should not

exceed twenty minutes and the cervix may be repaired, and any of the vaginal operations done, at the same time.

When there is extreme retro-displacement of the uterus, with prolapsed adherent ovaries, their removal will generally allow the uterus to regain its normal position, and the depletion incident to the curettement, repair of cervix, etc., will often permanently cure the patient.

If the retroversion is extreme, the uterus may be anteverted and stitched to the anterior vaginal wall after the method of Mackenrodt which is so highly indorsed by Martin, of Berlin; or in the hands of an expert the so-called Alexander's operation might be done after the finger had passed well around the uterus making sure there were no adhesions left.

I have performed vaginal oöphorectomy twenty times for the different conditions described above, including two for large gonorrheal pus tubes, and all have recovered from the operation, nor has there been any unfavorable complication, and I am sure that the after results have been much better than the same kind of cases for which abdominal section has been done. The difference in the amount of shock and the time required for recovery between the two methods can be compared with the same between vaginal and abdominal hysterectomy. I have searched in vain through my limited library to find the vaginal removal of ovaries recommended, and although my experience with the operation has not been extensive, I feel that the success which I have met may stimulate others to adopt it and write further on the subject.

The advantages I claim for the operation are as follows:

1. Rapidity of operation—twelve to twenty minutes.
2. Freedom from hernia.
3. Freedom from shock and vomiting.
4. Freedom from adhesions or intestinal injury.
5. Freedom from stitch abscess, causing long and tedious convalescence.
6. Natural drainage, preventing peritonitis.
7. The ease with which other operations upon the cervix and vagina may be done at the same time, which so greatly aid in restoring the patient to health.

## ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 482.)

### CHAPTER VII.

#### EXAMINATION OF FLUID BLOOD FROM CAVITIES OF HEART THREE HOURS AFTER DEATH.

The blood after its abstraction coagulated, forming a loose clot; the fibrin, however, dissolved and no serum was separated. Under the microscope the blood corpuscles presented no special alterations; when spread upon the glass slide, and also during the coagulation of the blood, they rapidly agglomerated together, forming rouleaux, as in inflammation in the blood of the horse. The running together of the colored corpuscles was as rapid and as complete as in cases of well marked inflammation.

It was impossible to determine the weight of the

fibrin, or to collect pure serum, free from colored blood corpuscles and the coloring matter of the red corpuscles, as the fibrin rapidly dissolved after its partial separation. The fibrin was in very small amount, and apparently not one-thirtieth of the usual proportion. Specific gravity of blood from cavities of heart, 1047.

1,000 parts of blood from cavities of heart contained:	
Water . . . . .	821.57
Solid residue 178.43 {	
Organic matters, colored corpuscles, albumin, urea, extractive and fatty matters, etc. . . . .	170.59
Fixed saline constituents. . . . .	7.84
Fibrin. . . . .	Traces

Three hours after death, specific gravity of blood from vena cava 1062. Blood fluid and warm when drawn; coagulated, forming a very loose coagulum, which did not inclose the whole amount of colored corpuscles. This coagulum gradually dissolved, and it was impossible to determine the amount of fibrin or to obtain clear serum free from colored corpuscles. Reaction of blood slightly acid.

1,000 parts of blood contained:	
Water . . . . .	775.00
Solid residue 225.00 {	
Organic matters, colored blood corpuscles, albumin, urea and ammonia. . . . .	217.31
Fibrin . . . . .	Traces
Saline constituents. . . . .	7.69

It will be observed that the blood in the vena cava contained more solid matter than that in the cavities of the heart; it would appear that the returning current of blood from the capillaries and venous system, owing to the tendency to coagulation and congestion, contained more solid matters than the blood of the heart.

No vegetable or animal forms were discovered in the blood.

Yellow fever blood exposed upon my table, in capsules and bottles for days and weeks, and examined microscopically from time to time, developed no special forms which could be referred exclusively to yellow fever. Only the simpler forms of animal and vegetable life made their appearance, which might be developed in any other similarly constituted albuminous fluid.

In a fatal case of yellow fever, occurring in one of my wards in the Charity Hospital during the month of October, 1871, in a stout young man, aged 25, who from the results of the post-mortem examination, had evidently suffered with malarial fever, incipient cirrhosis of the liver and granular degeneration of the kidney, before the supervention of yellow fever; death occurred after an illness of ten days; the disease was complicated during its progress by the supervention of pericarditis, pleuritis and pneumonia. The urinary secretion was abundant until near the close of life, and the urine contained blood corpuscles and the coloring matters of the blood. The cavities of the heart were filled with loosely coagulated blood. Portions of the lungs were infiltrated with blood, as if hemorrhage had taken place in and around the textures of the lung. Louis, in his "Anatomical, Pathological and Therapeutic Researches on the Yellow Fever of Gibraltar" of 1828, has shown that the exudation of blood into the pulmonary tissue was frequent, while the inflammation of that tissue was rare in subjects who had died of yellow fever. He found the lungs entirely natural in three subjects only.

Black spots, and masses of the same color, more or less impermeable to the air, were found in these

subjects usually of a brownish black, rarely of a crimson hue; they were more or less concentrated, and occupied a variable space at the exterior or in the interior of the lung, and in some cases they were found only in the lower lobe. The black or blackish masses which existed in the lungs of six individuals contained no air, had no granular aspects as in the hepatized lung of pneumonia and presented no traces of organization; usually they could be easily broken down, in some cases yielding by pressure; the blood of which they were almost entirely composed, and the pulmonary parenchyma remained apparently of its natural consistency. In this case complicated by the suppuration of inflammatory disease, the fibrin of the blood was not diminished to the extent usual in yellow fever. The pre-existing effects of malarial fever were evident in the masses of black pigmentary matter, derived from the hematin of the blood, scattered through the lobuli of the liver, but chiefly accumulated in the peripheral portions, in and around the portal veins and portal capillaries.

In uncomplicated yellow fever these altered masses of hematin are uniformly absent from the structures of the liver, their place is supplied by oil globules; and it would appear that in this disease the albuminous constituent of the blood and tissues is chiefly altered, the altered albumin appearing in abundance in the urine, while in malarial fever the colored blood corpuscles are chiefly attacked, the coloring matter being deposited in various organs, but in the acute stages of uncomplicated malarial fever, albumin rarely, if ever, appears in the urine.

The results of my investigations upon the occurrence of pigment in the blood and in certain organs, as the liver, spleen and kidneys, in the capillaries of the brain, in persistent intermittent and remittent malarial fevers, in chronic malarial poisoning, correspond with those of Meckel, Virchow, Heschl and Platner, and more especially with the researches of Frerichs. Not only is the spleen enlarged and the color of the liver altered to a steel gray, blackish slate and chocolate or bronze color, in individuals who die from the effects of marsh poison, but this change of color may extend to other organs as the kidneys and brain. Careful microscopic examinations of sections of the various organs have shown that these changes of color are clearly referable to the formation and accumulation of pigment matter resulting from destructive and abnormal changes of the colored blood corpuscles. While from the anatomic structure of the spleen, as well as from the great congestion which it undergoes during the cold stage of malarial fever, it is without doubt true that a large portion of this pigment is formed in the sinuses of the spleen and passes from this organ into the portal veins, and that part of it remains impacted in the capillaries of the liver, while the rest passes through these capillaries, and is carried into the general circulation; at the same time it must be admitted that under the action of the malarial poison, the transformation of the red matter of the blood into black pigment may take place everywhere throughout the vascular system, and also external to it, but more especially in the liver and kidneys. If fine sections of the malarial liver be made with Valentine's knife, and examined under comparatively low magnifying powers (one and a half to one inch), as I have done in a large number of subjects, accumulations of pigment will be observed in the capillary network of the portal

and hepatic veins, either uniformly distributed or limited to certain regions, sometimes deposited chiefly in the interlobular veins, forming black margins to the lobules of the liver; or more uniformly, extending from the circumference of the lobules halfway to their center, or penetrating as far as the beginning of the hepatic veins. The hepatic cells, as in the case under consideration, remain exempt from the deposits of black coloring matter.

That portion of the pigment originating in the spleen and passing through the capillaries of the liver, enters the general circulation and may be deposited in various organs as the brain, kidneys and lungs, inducing morbid symptoms varying in character and degree with the organ whose capillary circulation may be especially retarded by the arrest of the pigment particles. The larger particles remain impacted in the capillaries of the portal vein and obstruct the circulation of the blood through these vessels, causing various derangements in the secretion of the liver, and in some cases extensive capillary stagnation of the blood in the roots of the portal vein, attended with exhausting hemorrhages from the gastro-intestinal mucous membrane, of an intermittent character, profuse diarrhea, vomiting, serous effusions into the peritoneal sac and, finally, from the obstruction of many of the smaller branches of the portal vein, chronic atrophy of the liver, with its distressing and fatal consequences.

Even by simple inspection of the brain we may form some idea, not only as to the cause of the alteration from the color of health, but also of the amount of pigment which has passed unarrested through the vessels of the liver and lungs. The mechanical interruption to the circulation of the brain thus induced, not only gives rise to a peculiar train of symptoms, but may also cause the rupture of the small vessels and the formation of numerous capillary apoplexies, as has been shown so clearly by Meckel, Platner and Frerichs.

Frerichs has shown, and I have upon many occasions confirmed the accuracy of his investigations, that the large pigment granules and cells which enter the kidneys along with the arterial blood, not unfrequently become impacted in the capillary coils of the Malpighian bodies, and by altering the pressure of the blood give rise to derangements in the secretion of urine, which exercise a powerful influence over the further progress of the disease. Albuminuria, fibrinous casts, pigment masses and granules, blood corpuscles characteristic of the urine in malarial hematuria should to a large extent be referred to the effects of the pigment particles arrested in the capillaries of the kidneys. Hemorrhage, congestion, exfoliation of the excretory cells of the tubuli uriniferi, fibrinous exudation into the excretory tubes, and even complete suppression of the urinary secretion may occur in such cases. Destruction of the colored blood corpuscles may in like manner occur directly in the capillaries of the kidneys in malarial fever, and the pigment thus formed may give rise to a similar train of symptoms.

As far as my observations have extended, no such changes take place in the colored blood corpuscles and various organs in yellow fever—they are not destroyed in the various organs, neither is there a special diminution of these important elements, and all the organs and tissues are free from the presence of pigment granules in uncomplicated yellow fever.

If, however, as in the preceding case, the yellow fever occurs in one who has previously suffered with malarial fever, or if the disease supervenes upon yellow fever, then the pigment matter may be present to a greater or less extent, especially in the liver and spleen.

The result obtained by actual chemic analysis and careful microscopic research, viz.: that the colored blood corpuscles are not specially destroyed in yellow fever, as is the case in malarial fever, is still further sustained, by the well-established fact that, in general, convalescence is rapid and complete, and attended with a speedy restoration of all the healthy functions. Such a rapid and complete restoration would be impossible if the colored blood corpuscles were destroyed to any great extent in yellow fever.

During the latter months of 1870, when 587 deaths from yellow fever, were officially reported by the authorities of New Orleans, although the number was probably greater, as 445 deaths were during the same period (August, September, October, November and December), referred to the various forms of malarial fever, I instituted in like manner careful chemic and microscopic examinations of the urine, blood and black vomit of the various organs in yellow fever, and the results were similar in all respects to those recorded at length in the preceding pages; we shall for the sake of brevity simply allude to some of the more general results.

The type of the disease was severe and I saw cases in which the defibrinated blood oozed from leech bites, from the ears and from the gums and mouth; some cases suffered with profuse hemorrhage from the bowels before death. The bodies underwent putrefaction a very short time after death, having emitted during life a most disagreeable, foul yellow fever odor. The black vomit contained uniformly colored blood corpuscles variously altered; also mucous epithelium from the gastric mucous membrane; sometimes various matters, as medicine, food and drink taken by the patient; oftener numerous vibrios and plants resembling the torula and sarcinæ were present, but I was unable to detect any specific vegetable forms characteristic of yellow fever. The urine contained albumin and in the fatal cases was almost uniformly suppressed. In the worst cases the urine consisted only of a yellowish albuminoid fluid discolored by bile, containing little or no urea, but loaded with excretory cells and granular fibroid casts of the tubuli uriniferi. The lightest colored urine was frequently characteristic of the severest cases.

As a general rule, the blood changed to the arterial hue upon exposure to the atmosphere, and the cut and exposed muscles presented a beautiful scarlet color.

In some cases golden-colored heart clots of small size and slight consistency, composed of yellow laminated fibrin were observed in the cavities of the heart, and in those cases which had suffered with black vomit. Blood drawn from the cavities of the heart, after death from yellow fever, and carefully examined under the microscope presented swollen and stellate blood corpuscles. This stellate condition of the blood corpuscles appears to be very common in the blood of yellow fever, and even in that drawn from the veins during life. When a drop of yellow fever blood is allowed to fall upon white bibulous paper, the red corpuscles occupy the original area of the drop, and are surrounded by a golden circle of

the serum colored by bile. In any fatal case occurring during the fall of 1870, which fell under my observation, the serum was of a bright golden color from the presence of bile.

The nervous symptoms characteristic of this disease were referred, in great measure at least to the retention of the biliary matters in the blood, to the suppression of the function of the kidneys and the retention in the blood of the urinary constituents, especially of the urea in the blood.

The chief causes of death in these cases of yellow fever appeared to be the direct action of the febrile poison upon the nervous system and blood, depressing and deranging the one and rendering the other unfit for the proper nutrition of the tissues; the suppression of the functions of certain organs, as the kidneys and liver and the retention in the blood of the excretions normally eliminated by these organs. Blood loaded with bile and urea is evidently unfit for the maintenance of healthy nutrition and of the vital acts.

The hemorrhage from the gastric mucous membrane appeared to have been due to several causes, as the direct irritant effect of the poison upon the gastric mucous membrane, the destruction of the fibrin of the blood, the physical and chemical alterations of the albumin, and the irritant and dissolvent and *excoriating* effect of the carbonate of ammonia, resulting from the decomposition of the urea.

The black vomit in yellow fever, as shown by the observations upon numerous specimens obtained during life, and taken from the stomach after death, consists of altered blood corpuscles, the epithelial cells of the stomach, mucus corpuscles, various matters received into the stomach, as food, medicine, water, etc., serous exudations, acids of the gastric juice (acetic, hydrochloric and phosphoric), urea, carbonate of ammonia, and various forms of animal and vegetable life of simple organization.

After careful examinations of numerous specimens of black vomit, we failed to detect any forms which could be considered as characteristic of this fluid; which may not be developed in albuminous fluids exposed to the action of the atmosphere, at all times, whether yellow fever be present or absent.

The careful microscopic examination of the blood with the highest powers, was equally fruitless in disclosing any forms of animal or vegetable life which could be considered as active in the production of yellow fever, or as invariably accompanying its manifestations.

We have established by the preceding observations:

1. The blood in yellow fever often if not always contains abnormal amounts of *urea* and *bile*.

2. The presence of the urea and bile in the blood is attended with certain nervous disturbances.

3. It is probable that the extreme slowness of the pulse which characterizes many cases of yellow fever, after the subsidence of the first stage of febrile excitement, is due to the presence of the bile and urinary constituents in the blood, as well as to the anatomic lesions of the heart.

4. The fibrin is greatly diminished in the blood of yellow fever.

5. The passive hemorrhages and capillary congestion in yellow fever are without doubt largely dependent upon the diminution of the fibrin.

6. The colored blood corpuscles are not specially

diminished in yellow fever; and in this respect the disease differs widely from malarial fever.

Case of yellow fever engrafted on malarial fever; suppression of urine; black vomit; hemorrhage into gall bladder. Francis Dubucé; harness maker, age 32, native of France. Admitted Oct. 4, 1874, to Charity Hospital with intermittent fever; discharged October 9. After his discharge moved across the river to Gretna and followed the occupation of milkman. Some time, however, in the month of November, returned to the city and resided in Chartres Street in a neighborhood in which cases of yellow fever had occurred.

Entered Charity Hospital December 4. Had been sick with pain in the head, back and extremities for six days and had thrown up black vomit before entering Charity Hospital. Condition on entrance: deep yellow (jaundiced) color of skin and conjunctiva of eyes; sluggish capillary circulation; slow pulse; nausea; vomiting black vomit; temperature but slightly elevated above the normal standard. Urine of yellow color, turbid from the presence of urinary casts and cells from the urinary tubes and granular matter. Urinary casts as soon as the albumin coagulated by heat, presented a golden color. Diagnosis: yellow fever. The urinary excretion progressively diminished in amount, and toward the close of life, during the last thirty hours, was entirely suppressed. Died December 9, on the ninth day of the disease.

Post-mortem six hours after death. Exterior, head, trunk and extremities pale; surface of entire body of a golden color; the dependent portions being mottled of a purplish color. Black vomit issuing from corners of mouth. Head: blood vessels of brain congested with dark blood. Thorax: lungs normal; lower portions of darker color than upper portions, from settling of blood. Heart: yellow, flabby, softened muscular textures readily crushed between the fingers, and under the microscope the fibers of the heart presented the changes characteristic of yellow fever, the transverse striæ being indistinct, and numerous oil globules and yellow granular matter being deposited within and around the muscular fibers.

Abdominal cavity: mucous membrane of the stomach, of a deep purple color; with deep ecchymoses. Under a low magnifying power the ruptured mouths of the small blood vessels were clearly seen. The stomach contained several ounces of thick black vomit resembling putrid blood. Reaction of black vomit neutral. Specific gravity of black vomit, 1.032. Upon analysis, 1,000 grains of black vomit yielded 70 grains of coagulable albuminoid matters. After the removal of the albuminoid and coloring matters of the blood from the black vomit, the remaining liquid contained in addition to phosphates, sulphates and chlorids of the alkalies and alkaline earths, urea and salts of ammonia. Under the microscope, the morphologic elements of the black vomit were found to be colored blood corpuscles, mucus, corpuscles and cells from the mucous membrane of the stomach. No spores or vegetable organisms were observed. Upon standing, vibrios made their appearance in considerable numbers; but no fungoid growths were developed even at the end of forty-eight hours. The temperature appeared to be too low for the rapid development of the fungi. It is, however, worthy of note that the yellow fever had attacked this patient in the winter, December 1.

Liver: This organ presented on the surface a dark purplish mottled color; and upon a superficial examination presented nothing abnormal in color, except an increase in the depth of the normal shade. When sections of the liver were made, carefully washed and examined they presented a distinct and characteris-

tic mottled color, many of the lobuli being of the peculiar yellow color of yellow fever, and others presenting a variegated yellow and deep bronze color. Careful microscopic examination revealed the fact that the yellow portions were loaded with oil globules and yellow granular matter as in yellow fever, and that the more deeply colored portions contained numerous pigment particles as in malarial fever. The mottling of the usual yellow fever deposits, was due to the deposit of pigment particles in and around the portal capillaries during the preceding attack of malarial fever. Under the microscope the liver cells were found to be loaded with oil globules as in yellow fever; dark pigment particles were also scattered through the structures of the liver, but existed in greatest numbers within and around the peripheral or portal capillaries of the lobuli. The peculiar appearance of the liver in this case, was clearly the results of the combined effects of yellow fever and malarial fever; the latter having preceded the former.

**Gall bladder:** the gall bladder was distended with a dark fluid of a brownish and reddish black color, and upon a superficial examination resembled this viscus in malarial fever. When the bile was poured out it resembled in appearance dark liquid blood. Specific gravity of the fluid from the gall bladder 1021.5; reaction neutral. Amount of fluid in the gall bladder 1,600 grains. Heat and nitric acid caused coagulation; coagulum of a dark mahogany color like that always formed in liquid blood under the action of heat and nitric acid.

Under the microscope, the fluid from the gall bladder was found to contain numerous altered colored blood corpuscles and epithelial cells of the mucous membrane of the gall bladder. The mucous membrane of the gall bladder was of a deep purple congested color, resembling in all respects the deeply congested and purple mucous membrane of the stomach. Amount of coagulable albuminoid matter in 1,600 grains of bloody liquid from the gall bladder, grains 44.70. Nitric acid produced no change of color, similar to that caused by the coloring matter of the bile; numerous tests also repeatedly and carefully applied failed to show the presence of the biliary acids. The reagents simply caused coagulation of the albumin, as in ordinary liquid and diluted blood. The filtrate obtained after the coagulation and removal of the albuminoid elements of the blood was found to be loaded with urea. The liquid therefore found in the gall bladder was not *bile* but *altered liquid blood*, similar to that poured into the stomach and called black vomit.

We have in this case and in the preceding facts, a striking and important illustration of the sources of error in the investigation of the pathologic anatomy of yellow fever. Superficial observers here and elsewhere have proclaimed that yellow fever had no distinctive pathology. Such assertions possess no value unless based upon the most careful and thorough microscopic and chemic investigations.

**Kidneys:** these organs presented a yellow color resembling that of the heart. When sections of these organs were made with Valentin's knife and carefully examined under the microscope, the Malpighian corpuscles and tubuli uriniferi were found to be loaded and impacted with desquamated cells, oil globules and yellow granular matter.

Yellow fever engrafted on intermittent fever, suppression

of urine; black vomit; death; hemorrhage into gall bladder. E. Johnson, age 27, native of New York, laborer. Came to New Orleans in January, 1874. Went from this city to work on jetties at the mouth of Mississippi River. Entered Charity Hospital Nov. 20, 1875. Patient stated that he had been suffering with intermittent fever for one month. Walked about the ward until the evening. I saw him the next morning, November 21. Has rapid pulse and high fever. Quinin was administered freely but without any effect upon the fever. November 22, fever continues; patient very restless; eyes injected; tenderness over region of liver, epigastrium and small of back over the kidneys. Has been vomiting. Quinin repeated, but without any beneficial effects. November 23, fever declining; great capillary congestion of face, neck and extremities; yellow tinge of surface; very restless and delirious; injected eyes; urinary excretion greatly diminished. November 24, heat of body almost normal, but capillary congestion intense and jaundice increasing. Urinary excretion greatly diminished and in fact almost wholly suppressed; delirium; has vomited dark "coffee ground" matter. November 25, restless and delirious; pulse 68; respiration 25; temperature of axilla 95 degrees. Head, trunk and extremities feel cool. Great capillary congestion of surface which presents a purplish and mottled appearance, with a distinct golden color; complete suppression of urine. Upon careful examination the bladder is found to be entirely empty; great prostration of muscular and nervous systems; patient delirious and restless. During the past two days it has been impossible to arouse the patient or to obtain from him any coherent answer; 6 p.m., pulse 68; respiration 28; temperature of axilla 95.5 degrees. The patient died one hour after this observation.

**Necropsy** thirteen hours after death: Exterior, trunk and limbs full, round and plump; skin yellow; dependent portions of head, neck, trunk and extremities present a purplish mottled appearance. Thorax: heart, yellow and softened; weight nine and five-eighths ounces. Transverse muscular striæ indistinct; oil globules and yellow granular matter deposited in large amount, within and around the muscular fibrillæ of the heart. Lungs normal; dependent portions congested. Abdominal cavity: liver yellow and enlarged. Under the microscope, sections of the liver, with Valentin's knife, presented the characteristics of the yellow fever liver; immense numbers of oil globules of various sizes, and yellow granular matter deposited within and around the cells and capillary networks of the liver. The liver also contained pigment particles, resulting from the preceding attack of malarial fever.

**Gall bladder:** The gall bladder contained 421.4 grains of thick, deep green, almost black, tenacious bile, which poured with difficulty and could be drawn out into long strings. When heated the whole mass coagulated firmly, resembling in this respect albumin or liquid blood, colored by biliary matter. Under the microscope the bile was found to contain an immense number of desquamated cells from the mucous membrane of the gall bladder, also colored blood corpuscles and masses of hematin. Mucous membrane of gall bladder greatly injected and discolored, of a deep purplish and greenish color. When held up to the light a dense network of deep purple and black congested capillaries and blood vessels were everywhere discoverable. Solid coagulable matters in 421.4 grains of bile, grains 77.4; solid matters in 1,000 parts of bile, 183.67. The contents of the gall bladder were so thick and tenacious that it was impossible to introduce them into the ordinary specific gravity bottle.

It is evident that hemorrhage had taken place into the gall bladder. Stomach distended with black vomit, resembling dark fluid blood; the intestines also contained much black vomit, of a character similar to that found in the stomach. The great de-

pression of temperature, about 4 degrees F. below the normal standard, which characterized the last twenty-four hours of life may have been due to the profuse hemorrhage into the stomach and bowels. Under the microscope the black vomit from the stomach presented nothing more than mucus corpuscles, desquamated cells from the gastric mucous membrane, broken capillaries, and immense numbers of colored blood corpuscles. I observed no vegetable nor animal organisms. Their absence appeared to be due chiefly to the depressed temperature of the surrounding atmosphere. Kidneys engorged with blood; when divided and washed, they presented a yellow color like that of the liver. Weight, seven and one-eighth ounces. Chemic analysis showed a great increase of oil in the structures of the kidneys, as well as of the heart and liver. When sections of the kidneys were made with Valentin's knife and carefully examined under the microscope, the Malpighian corpuscles and tubuli uriniferi were found to be impacted (literally-stuffed) with detached cells, oil globules and yellow granular matter. The urinary bladder contained only two fluid drachms of urine, which represented the whole amount of urine excreted by the patient, during the last twenty-four hours of life. The urine contained albumin and numerous casts of the tubuli uriniferi, filled with yellow granular matter and oil globules, also cells from the pelvis and ureter, and from the mucous membrane of the bladder. The urine contained, also, little or no bile and presented a yellowish red color.

In this case the disease was contracted at the jetties near the mouth of the Mississippi River, where fever prevailed to a limited extent among the laborers, late in the season. One or more barges upon which the workmen slept at night became infected, and it was found necessary to destroy them by fire.

(To be continued.)

## SOCIETY PROCEEDINGS.

### American Electro-Therapeutic Association.

*Fourth Annual Meeting held in New York Academy of Medicine, New York, Sept. 25, 26, and 27, 1894.*

WILLIAM J. HERDMAN, M.D., President.

(Continued from page 491.)

PROF. A. E. DOLBEAR, of Tuft's College, Boston, read a paper on

#### PHYSIOLOGIC EFFECT OF THE CURRENT.

In the early days of electrical applications to therapeutics no one knew what to expect. At best it was thought that electricity was a very mysterious something with limitless possibilities, but unless the patient could feel its effects it was thought nothing happened. Again, it was held that electricity was electricity, and induction coil discharges which could be felt were proper for all sorts of diseases when it could be applied. As there were no units, no one knew what or how much he was giving or taking.

The cautious physician very properly would not venture to employ an agent he knew little or nothing about, while the quack with his mysterious machine and wise look, often succeeded in inspiring his patients with confidence in himself and a high degree of expectancy which, as every physician knows, are of high therapeutic value for the larger number of ailments he is called upon to treat. He therefore sometimes surprises himself and others by his success where they had failed, and electricity got all the glory for success while the failures were never counted.

Now that one may know exactly the nature of the current he uses as well as its quantity, the successful application to physiologic purposes has begun in an intelligent way.

At the outset one has to make the inquiry whether electrical action in the body and out of it are or not radically

different. Are there physiologic conditions which dominate, or is electricity in the body as well as out of it, subject only to its own laws?

The physiologists and biologists have quite given up what was called "vital force," and stoutly maintain that in the last analysis all physiologic processes are physical and chemical. If that be granted then one may start with the assumption that the only difference in the action of electricity in a living body and out of it, are differences in the degrees of complication. I believe that it is conceded among physicians who have studied the physiologic effects of electricity that the immediate effects are altogether physical and chemical.

Assuming this to be true, one may inquire what are the physical and chemical effects of electricity, in order that he may look for them in physiologic processes.

1. A current of electricity always heats the conductor through which it goes, and this quite independent of how much work of other sorts may be done in the same circuit. Whether it be turning a motor or lighting an arc or incandescent lamp, or decomposing a chemic compound, or any other, these simply cut down the current in their circuit, and the heating power is proportional to the square of the current. So one may conclude that when an electrical current is sent through any part of the body, that part is more or less heated. With such currents as are employed in everything except perhaps in electrocution, the heating effect is so small as to be wellnigh ignorable. A current of 1 ampere in a resistance of 1 ohm will raise the temperature of a pound of water only one-hundredth of a degree in a second, but the resistance of the body is to be reckoned by thousands of ohms and the currents employed in thousands of an ampere. A current of 10 milliamperes or the hundredth of an ampere through 1 ohm would heat it only one ten-thousandth of one hundredth, or the millionth of a degree in a second, or, to state it in another way, would require nearly two weeks to heat a pound of water 1 degree.

2. A current will produce light, as is evidenced in the arc and incandescent lamps, but the light is the effect of the higher temperature, for it is the carbon raised to incandescence which is the cause of the light and as the heating effects are so minute no luminous results due to incandescence can be expected in physiologic applications. There is another kind of luminousness observed in rarified gases when alternating currents of high voltage are sent through them, but they are not observable in solids and liquids and there is no evidence that there is any corresponding physiologic effect.

3. A current may bring about chemic decomposition. A typical case of this is the decomposition of water. To effect this an electro-motive force of as much as  $1\frac{1}{2}$  volts is necessary, as the electro-motive reaction of water composition is  $1\frac{1}{2}$  volts. When a single cell such as any of the ammonium chlorid cells is employed directly for physiologic purposes, water decomposition can not be expected, but where the same cell is used with an induction coil the voltage which comes from the secondary cell with hundreds or thousands of turns may be reckoned by the hundred. In this case water would be fully decomposed at both electrodes, both oxygen and hydrogen being set free. If there were no other substance than water present, these elements would at once be re-combined so that no collection of gas would be observable, nevertheless there is every reason to believe that even here the same hydrogen and oxygen would not be combined into a given molecule, but the decomposed molecules would have changed partners. In the presence of other substances than water there is every reason to expect other combinations at both poles and what the product would be would depend upon what substances were present at the places, also their looseness of chemic structure. The substances of the electrodes themselves might be attacked as, for instance, copper or silver might be slightly oxidized and hydrogen freed or not, depending upon the quality and conditions of the adjacent molecules. The point here is that one must not assume that chemic decomposition of water does not take place because he can detect no evidence of free oxygen or hydrogen. Whenever a current can enter the body it enters it through its fluid conductors, chiefly water; dried tissues of all sorts being non-conductors.

4. An electric current will make a magnet, or rather it is a magnet itself. The current in a conductor of any kind endows the substance of the conductor for the time with all the qualities of magnetism. It possesses a so-called magnetic field with either tension concentric with it, and a magnetic needle tends to set itself at right angles to it, and this is as true for the body or part of the body through which a cur-

rent goes as it is true for a piece of copper or iron wire. If the current be a continuous one, such as one gets from a battery, the needle will indicate it by swerving from the meridian. If it be an interrupted or alternating current the needle may show no sign of movement because it takes time for it to move, and if it be solicited to move in one direction and before it has had time to turn it be solicited to move in the opposite direction, it will stand apparently still, but it would be wrong to infer that the needle was unaffected. With such small currents as are used for physiologic purposes such magnetic effects would only be observed by working with delicate needles.

The magnetic field, whatever its source, reacts in some degree upon all kinds of matter within it. Upon what we call magnetic substances such as iron, nickel and cobalt it acts to set them in positions in its own lines. All other substances are set in positions at right angles to these. These phenomena are known as para magnetic and dia magnetic phenomena. Excepting iron and nickel, these effects are weak with ordinary currents and at ordinary temperatures, but they are exalted at low temperatures. What I would emphasize is, that in a magnetic field, all kinds of molecules are acted upon by a pressure tending to twist them into new positions, and this must be true in the body of a living thing as it is for things external to it. If on account of opposite pressures a given body does not move at all, then is it subject to what in mechanics is called a strain. Its form has been more or less distorted. As I am not now concerned with amounts of distortion or changes in position, it does not matter whether the actual quantity be of one value or another. By coiling a wire through which an electric current flows, the magnetic field of a greater length is concentrated within it and the effects are correspondingly increased, but they differ only in degree from that shown by any part of the circuit. With a constant current from any source to provide a magnetic field, with or without coiling the conductor, or with a permanent magnet of any form, the field is a constant stress and acts upon all bodies in it in some degree. As doubtless you are all aware, there have been many attempts to discover this field by sensation. Lord Kelvin tried it years ago and expressed some surprise that there did not appear to be a magnetic sense.

Peterson and Kennelly have more recently tried it with exceedingly strong fields and they have concluded that "the human organism is in no wise appreciably affected by the most powerful magnets known to science."

As to such conclusions, I would suggest that the explanation of the failures to perceive any effects might be attributable to two causes:

1. A magnetic field acts upon molecules, not upon physiologic organs as such. There is no tendency to twist, warp or strain a muscle as such, and hence sensory nerves for muscular movement would have nothing to report.

2. A constant stress of light value does not give rise to sensation for ordinary mechanical causes. Lay the arm carelessly and without looking at it, on the table where it can be comfortable and for a short time turn the attention to other matters. Then without looking at the arm or moving it in any way, see if you can tell how the fingers are crooked, or which ones touch the surface of the table. Not until some muscles be moved can one tell what shape his hand is in and yet it has been subject to constant pressure all the time. For this reason then, that a constant pressure producing no movement ought not to be expected to give a perception, I am not surprised at the results reached.

3. A magnetic field, whether constant or varied, has no chemic effect. It does not bring atomic changes. Such changes require energy of a different sort, and any nerves whose function it was to respond to chemic changes would not find anything to report from a magnetic field.

As for the brain itself which has been exposed to the strongest available magnetic field for considerable lengths of time with no results noted, I would ask why one should expect sensory results from an organ which is itself not sensitive? Can not the brain itself be dipped out with a spoon without sensation? Sensation implies nerves, and particular sensations particular nerves, and there are no substitutions. Neither the white nor the gray matter possesses nerve cells. If the brain were affected by a magnetic field, I should expect it would need to be detected by other means than by the direct sensation. I therefore conclude that the experiments alluded to, prove that magnetic effects do not produce the mechanical and chemical changes necessary for sensation, rather than they are absolutely without any effect. This latter conclusion, if adopted, would at once demand the acceptance of the proposition that electrical

effects are not the same within the body as they are without, and that would necessitate in physiology the revival of a vital force or something like it.

4. An electric current in a given conductor induces another electric current in an adjacent conductor. It does this by virtue of the magnetic field which it forms about itself and a moving magnetic field, however originated, acts in the same way, to set up an electric current in neighboring conductors. The so-called induced current lasts no longer than the field, is changing in strength, and quite stops when the field no longer changes, no matter how strong the latter may be. Hence it is possible to set up electric currents in any conducting body without having any electrical conductor between it and a primary source of electricity. This is the principle employed in telegraphing without wires between two points. Whether such a method has any physiologic importance I do not know, but I should think it might sometimes, where currents of particular frequencies or character are desirable and not so easily to be had with an electro-magnetic breaker as in the ordinary induction coil. In another way it has some theoretical interest. It has been reported that anesthesia may be brought about by subjecting a part of the body, a finger for instance, to an alternating magnetic field. This, observe, is not sensation but the absence of it; there is nothing in the reports of the experiments with magnetic fields to show that tests of sensitivity were tried; they were probably not tried in any.

Now, I believe it has been demonstrated that alternating electrical currents at some unsettled but very high rate of alternations can for the time being destroy sensation, so that I say a tooth may be pulled without pain. If there be nerves of sensation in an alternating magnetic field, and they be made a part of an electric circuit as they very well may be made, then changes of magnetic polarity may bring about current changes in the organism and these may have any of the results that belong to currents, and if currents under any conditions will produce insensibility then the effects between magnetic poles will be due, not to the magnetism itself, but to the currents of electricity which the magnetism induces.

I have heard it objected to the view that magnetic fields could produce any physiologic effects that, if so, those who work with alternating currents of electricity and especially such as are near dynamos and motors would have noticed it, yet none have ever reported it. If, however, the real effect was one to lessen their sensitivity in general, one would hardly expect one to know anything about what had happened without comparisons. Experiments need to be made for all the nerves. Can one see or hear or taste or smell or touch as acutely in such a varying magnetic field or with alternating currents as he can without them?

If there is anything at all in this anesthesia by currents without bringing on tetanus, I should suppose it would have a wonderful field. For instance, in seasickness there could be found a current of some degree and frequency that would be quite insensible to the feelings, which would prevent at once the nervous condition, and an electrical device could be worn continuously on shipboard without discommoding one. The chief difficulty, I should suppose, would be to find the proper route for the provided current. If, for instance, the immediate cause of seasickness be, as I have somewhere read, the movements of the fluid in the semi-circular canals, then electrodes might need to be fixed in the ears.

Then again, it is now well known that electric currents are generated in the body by the contraction of muscles as well as well as by chemic action wherever these may take place. These currents are exceedingly weak, too weak to be able to do any of the wonderful things that are alleged to be due to them by so-called "magnetic" healers. It requires the most delicate apparatus we have to detect them at all, nevertheless, an electric current always has direction and a conducting circuit. The query is, Which are the conductors in the body? The nerves have often been compared to conductors and some have thought that the impulses in them called "nervous transmission" were electric currents; on the other hand, the measure of the rate of impulse has been found to be so low—less than a hundred feet a second—that some have concluded that such nervous current could not possibly be electrical, inasmuch as the velocity of electricity is reckoned to be so great. This has never seemed to me to be conclusive. The old experiments on the velocity of electricity did not measure that at all. They at best indicated the rate of flow of a certain amount of electrical energy, which is a different problem. If a conductor be a poor one it may take a good while to get enough electricity through it to produce any observable result, and that I think, is the

case with the electric conductivity of a nerve. Aside from the nerves, there are the blood vessels filled with good conducting materials, muscular tissue of various kinds not so good, and fatty tissue almost non-conducting, so that what will be the route of an electric current between two points in the body, may not be the same in different persons. I should expect that a given current would be much the densest in a lean or muscular person and much scattered by adipose tissue; even a large surface electrode of a square foot which will carry a current of 22 milliampères without injury to the surface itself might, on account of the slight conductivity of the underlying tissues, be made destructively dense in some portion of its course. I can not give an example but think it probable.

And last, but not least, what may be said of electricity as a curative agent? If one can not give a technically correct description of electricity itself yet this we do know, that an electric current is the bearer of energy in such a form as to be readily available for mechanical, chemical or magnetic effects, and which of these will be the result depends altogether upon what kind of mechanism is provided for it. Inherently, electricity has neither curative nor destructive qualities. I do not think there is any evidence that it attacks life or that in any sense it is life, as some have thought. One might as well say that heat is life or chemism is life. Electricity has directly to do with molecules and atoms. It can shake molecules apart and permit new molecular arrangements. If these new products chance to be useful or harmful to the organism it will be benefited or injured. The particular advantage, which is a very great one, is these products may be produced where they are wanted. This is now practically applied in electrolytic and catalytic adaptations. Its electro-tonic action may be due more to the electrolytic products at nerve terminals than to their direct excitation. Considering a nerve as a conductor, its quality does not depend upon its conductivity but its conductivity depends upon its quality. It is not quite as probable that if for any reason nerve action is judged to be slothful it is due to the fact there is nothing to conduct, that is, the metabolic changes at the nerve terminals are not rapid enough, as that the trouble is due to the nerve itself? This supposes the nerve to be intact.

I can not forbear to allude to a matter of high theoretical interest directly related to electro-therapeutics. Since it has been practically demonstrated that what we call light is a set of ether waves of electro-magnetic origin, it has been apparent to some, though others have not seen the significance of the work, that we are compelled to postulate that all atoms are magnets, seeing that all can and do give electro-magnetic waves. There was a good deal of reason for thinking so before. This new evidence seems to compel one to assume it. Hence, on this assumption, it follows that the living body is but a combination of an enormous number of atomic magnets. I use the term atomic advisedly, for molecules are but combinations of atoms, and their properties are only the resultant properties of the atoms that make them up. Every movement of every molecule and atom in the body is, then, a magnetic movement in magnetic fields and must induce magnetic and electric changes all about it. It was long ago shown by Faraday that electric and chemic changes were quantitatively related. Now it is seen that electro-magnetism underlies all chemic action. The significance of it here lies in the fact that in working with electricity to effect physiologic changes one is really at work with the fundamental factor in physiologic energy. Not in a roundabout but in the most direct way.

Functions of all sorts are electro-magnetic in the last analysis, and he who understands these and the art of properly applying electro-magnetic energy to languishing or diseased organs will be able to do all for humanity that skill can do. The more I study the relation of life to the things upon which it depends, the more I am persuaded that though death may be for the benefit of the race, it is not necessary for the individual.

#### DISCUSSION.

DR. J. H. KELLOGG said that the paper was very suggestive for future research, but as the ideas presented were largely theoretical, we should, before accepting them as facts, supplement them with physiologic and other experiments. Some experiments that had been made showed that muscles were electrical accumulators—they could be charged by contact and discharged by contact or induction. If these experiments were confirmed they would go far toward corroborating the statements made in the paper.

DR. MORTON said he would like some further light in regard to the electro-magnetic molecule. Did the author mean by that the chemic affinities which were taking place and which constituted the sum total of life, or did he mean that we should consider each molecule as showing a certain amount of polarity, and yet not necessarily associated with chemic affinity?

PROFESSOR DOLBEAR said that in his paper he had asserted that we had been compelled to assume that atoms and molecules were magnets, and that there was a good reason for thinking so before the experiments by Maxwell and others had forced this conclusion upon us. All were probably familiar with the experiments that had been made recently regarding the conductivity and magnetic changes. At absolute zero the conductivity was an infinite quantity—there was no resistance—and the graphic representation of the conductivity of the body was a straight line. At zero, the chemic affinity was at zero, hence chemic affinity would seem to be a necessary outcome of temperature. He did not understand that magnetism had necessarily anything to do with chemic affinity—he would entirely disassociate the two.

THE PRESIDENT remarked that though many of the statements in the paper had been characterized as theoretical, they were largely founded on physiologic facts.

(To be continued.)

## SELECTIONS.

**Non-Surgical Treatment of Hemorrhoids.**—The *Gazette des Hôpitaux* lays down the following indications of hemorrhoids which should not be operated on: 1. Symptomatic hemorrhoids, sometimes due to stricture or cancer of the rectum, to affections of the prostate, bladder or urethra; sometimes they are caused by a gravid uterus, a fibro-myoma or an ovarian cyst pressing on the pelvic veins; again, they may result from cirrhosis of the liver. In all these cases the primary cause should be treated; an operation is at least useless if not dangerous; 2. Hemorrhoids without any important symptom. Some patients experience neither uneasiness, pain nor hemorrhage. They are obliged to watch the condition of their bowels, but are not otherwise incommoded; 3. The most important class for non interference with the knife is the prolapsed, strangulated or prolapsed. These are really cases of infectious phlebitis and an operation is not without danger. In all cases the patient should adopt certain prophylactic measures. All irritation of the anal region should be avoided; constipation, with a large hard stool, should be controlled by appropriate diet, the use of laxatives, etc.; the bowels should be moved as nearly as possible at a certain hour so as to induce regularity and should be followed by ablutions of warm water, either plain or borated. Injections of boric acid are recommended as controlling congestion as well as facilitating defecation. If small bleedings occur it will be useful to give large injections of water at 40 to 45 degrees and local applications of sponges or tampons of water at 50 degrees. If the congestion is prolonged, if there is inflammation and danger of gangrene, hot applications are indicated, but it will be found well to employ certain topical agents—either calomel or tampons saturated with glycerin 35 grams, iodine 20 centigrams to 1 gram, iodide of potassium 2.5 grams. The applications are slightly painful and it is best to begin with the smaller proportion of iodine. The use of soothing ointments is often indispensable—the old-fashioned poplar ointment answers very well. It can be associated advantageously with belladonna and antipyrin—*e. g.*, poplar ointment 30 grams, antipyrin 2 grams, extract of belladonna 1 gram. Irrigations with laudanum or antipyrin also give excellent results. The oozing and irritation which often complicate external hemorrhoids usually cease with cleanliness and the use of boric acid solutions. It may be well to use between the irrigations a pad of cotton impregnated with borated vaselin or to powder the part with some inert absorbent powder, such as subnitrate of bismuth.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

## SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

## MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, APRIL 6, 1895.

## DAMAGED BY FIRE.

March 31, being Sunday, the employees of this office were enjoying that rest which all good people enjoy on that day. It so happened that in the afternoon Mr. R. A. HAMILTON went to the JOURNAL office on an errand for the Editor. He was in the office a few minutes, found the papers of which he was in search, closed the iron door, and started home; going down the stairway he smelled smoke, and he looked carefully on each landing as he passed, finding the smoke grow thicker, and on reaching the first floor found the stairs themselves on fire. He ran to the basement, called the engineer of the building and had the alarm sounded. In four or five minutes the entire hallway and stairs were wrapped in flames, and sheets of fire rushed out of the windows.

The insurance patrol responded quickly, and in less than six minutes from the time of sounding the alarm, the JOURNAL presses, the machinery and type were covered with tarpaulins. The fire engines were playing on the fire in the hallway in about ten or twelve minutes.

Two of the Trustees and the Editor arrived in about an hour to find the fire practically extinguished but the office was flooded with water; the desks and movable furniture about six to eight inches deep in water, much type "pied" and manuscripts water-soaked.

The JOURNAL, nevertheless, appears on time, the

loss is nearly covered by insurance, and our members may well be thankful that the situation is no worse. Our employees have been obliged to work in a room without heat, and in much discomfort. But for the timely discovery of the fire the loss would have been complete.

This is the second time the JOURNAL has suffered by fire. The printing firm of BLAKELY & ROGERS had in 1888 the contract for press work, and a fire broke out which caused serious damage. On that occasion the forms were destroyed and only a portion of the paper could be made ready in time for the weekly issue.

## THE NEW YORK COUNTY INSANE AND EPILEPTICS.

The pauper insane of any locality would seem to have a poor outlook, when those whose duty it is to advocate their interests sneer at others who volunteer on behalf of those interests. The State Charities Aid Association, now in its twenty-third year of proposed support of the charitable operations of the State of New York, has apparently adopted the rôle of apologists to those who run the institutions of the metropolitan city. In its last annual report the "whitewash" is applied as follows: "It would be useless to repeat *facts* which have been dinned into the ears of the public for several months past with regard to the many deficiencies of our city asylum." The fact that the charitable and correctional institutions are under one commission is adduced as one of the reasons why these facts exist, when the truth is that in years gone by the one commission, when in the hands of other men, conducted wellnigh faultlessly the affairs of both the sick and the criminal. The inference is that the men who get appointed to the commission are not large enough for their work, or are giving their time to less important matters; they should be divorced from ward politics and be required to personally visit the institutions under their charge. The Annual Report, from which the above is quoted, adverts to the progress that has been made toward the establishment of a colony for epileptics. It thus refers to the philanthropist, after whom the colony will be named:

"The late President, of your Board, MR. OSCAR CRAIG, died on Jan. 2, 1894. MR. CRAIG was not a member of this Association, he was not a resident of this city, but he used his high and honored official position to strengthen the hands of all who are striving to raise the down-trodden and succor the helpless. For this is what he did himself. The insane, the prisoner, the poor epileptic found in him a friend, ready at all times to do battle in their behalf with voice and pen. Strong in his singleness of purpose, his great moral courage and extraordinary industry; gentle, because so strong; just, because so true; these qualities made MR. CRAIG a power for

good. He was the firm friend of this Association, using his great influence to promote our reform measures, however unpopular, when once satisfied they were beneficent of purpose and sound in principle. Nor did he ever lose an opportunity of bearing public testimony to the value of organized volunteer aid united with official service, illustrating it by the work of this Association in connection with that of his own Board. The last occasion on which MR. CRAIG addressed a public audience was in Chicago, at a Congress of the World's Fair, and the last words uttered by him there were to urge the formation of State Charities Aid Associations in every large State in the Union.

MR. CRAIG did not live to see established the State Colony for Epileptics, to which he had given so much time and thought. As Chairman of the Committee of your Board which selected the site, as author of the bill of the Association, introduced in 1893, and as one of its most earnest supporters in the Legislature, he was so identified with this great reform that when our bill to establish the Colony was introduced a second time, in 1894, a few weeks only after MR. CRAIG'S death, we gratefully paid him the highest honor in our gift by naming after him the State Colony for Epileptics. That the original suggestion should have come from the Governor of the State is an additional tribute to MR. CRAIG."

#### THE CRIMINAL USE OF CHLORAL.

This JOURNAL has from time to time adverted on the necessity for some general legislation to prevent criminals from purchasing deadly drugs, and recently the use of chloral by criminals for criminal ends has been made the subject of an investigation by the captain of that notorious New York precinct called "the Tenderloin." Having been informed that the so-called "knockout drops," that have the name of completing the work of alcohol in the operations of thieves who desire to stupefy and afterward clean out their partially intoxicated victims, contain chloral, CAPTAIN PICKETT has sent out a detective to investigate the sale of chloral and other stupefying drugs. He has found that it is altogether too easy to purchase chloral at the drug stores. He is inclined to regard the law relating to the purchase and possession of poisons, as weak and not up to date, for the reason that it does not provide for the detention or punishment of persons having the "knockout drops" in their possession, who may have been arrested on suspicion. He states that the offense is grave enough to make it a felony to the person on whom is found the drug for any unlawful purpose. The druggists who sold chloral indiscriminately to the detective will be prosecuted. A case of death has recently been held to be referable to these "knockout drops."

#### TO CHAIRMEN AND SECRETARIES OF SECTIONS.

Section officers are respectfully requested to send their completed program to the JOURNAL at the earliest practicable date, and no later than April 17. The

program will hereafter be printed in the JOURNAL office, and it will appear in full in the JOURNAL of April 20.

#### PHOTOGRAPHS OF MEMBERS.

We have received a great many photographs of the members of the ASSOCIATION, but nevertheless a very small percentage of the whole membership. We wish to have the collection as complete as possible, and therefore respectfully request those who have not done so to send their picture by return mail.

Do not forget the JOURNAL SPECIAL TRAIN leaving Chicago Sunday, May 5, from Pennsylvania depot, 3:15 A.M. Write for space desired.

P.

#### BOOK NOTICES.

**A Course of Elementary Practical Bacteriology, including Bacteriologic Analysis and Chemistry.** By A. A. KANTHACK, M.D., M.R.C.P. and J. H. DRYSDALE, M.B. M.R.C.P. Pp. 181. London and New York: Macmillan & Co. 1895.

This manual is a hand-book for the bacteriologic laboratory written by practical workers. The matter is logically arranged, and carefully pruned of unnecessary words. Each subject is made easy by every detail being explained; no step of any ordinary procedure is left in the dark. There are three parts: Part I is on General Bacteriology (16 lessons); Part II, Bacteriologic Analysis (12 lessons); Part III, Bacteriologic Chemistry.

We commend this laboratory guide to practical students in the highest terms.

**E. Brissaud, Leçons sur les Nerveuses (Salpêtrière 1893-1894) recueillies et publiées.** Par HENRY MIEGS, avec 240 figures (schémas et photographies). Paris: G. Masson, 1895. Pp. 644.

On the death of the lamented Charcot, M. Brissaud was called to occupy provisionally the Chair made famous by the great master.

There are thirty lectures in this volume, of the seventy lectures of the course, which are carefully prepared, and very interesting. Of these lectures the first is devoted to a eulogy of Charcot, touching in its tenderness, and broad in its understanding. The other chapters are I to II, Charcot's Disease. (Lateral amyotrophic sclerosis); III, to IV, Friedreich's Disease (cerebellar hereditary ataxia); V, Paraplegia Ataxo-spasmodic and Tabes Combined; VI, Little's Disease and Dorsal Spasmodic Tabes; VII, Paraplegias of Potts' Disease. Prognosis and Surgical Treatment; VIII, Hematomyelia and Sudden Paraplegias; IX, The Reciprocal Relations of Hypertrophic Cervical Pachymeningitis and Syringomyelia; X, Syringomyelia, Histology, Metamerism of the Sensory Centers; XI, Spinal Syphilis; XII, Spinal Hemiparaplegia with crossed Hemianesthesia, Syndrome of Brown-Séquard; XIII, On the Abolition of the Muscular Sense and on the Sign of Romberg; XIV, Tabetie Arthropathies and Sensory Troubles; XV, Trophic and Sensory Disturbances; XVI, Exterior forms of Myopathy; XVII, Ophthalmoplegia in General; XVIII, Orbital and Subpeduncular Ophthalmoplegia; XIX, Intrapuduncular and Nuclear Ophthalmoplegia; XX, Neuritic Ophthalmoplegia and Neuritic Muscular Atrophy; XXI, Spasmodic Laughing and Crying; XXII and XXIII, Pathology and Symptoms of Parkinson's Disease; XXIV, Tics and Clonic Spasms of the Face; XXV, On Aphasia of Articulation and of Intonation, in connection with a Case of Cortical Motor Aphasia without Agraphia;

xxvi, Sensory Disturbances in Hemiplegia of Cortical Origin; xxvii, Syndrome Cerebellar; xxviii and xxix, Basedow's Disease—Exothyropey; xxx, Myxœdema, Cretinism and Infantilism.

The profound scholarship and vast experience displayed in these lectures not only prove that M. Brissaud is not unworthy to succeed Charcot, but that he is able, eloquent and conscientious. No more interesting lectures have ever been written on this subject, than those in the volume of M. Brissaud. We have to thank him for one of the most instructive and entertaining books of the year.

## PUBLIC HEALTH.

**Obligatory Vaccination Abolished.**—Obligatory vaccination is to cease in the Canton of Berne, Switzerland. An election just held showed that the anti-vaccinists cast 26,238 votes against 24,543 by their opponents.

**Vanillism.**—M. Guerin, Officer of Health for the Colonies, reports—*Rev. Int. Med. Prat.*—that since the researches of Layet, two sorts of vanillism are recognized—the alimentary, with choleric symptoms produced by eating vanilla ices; and the professional. The latter is due to the odoriferous principle of vanilla, or vanillin, and may give rise to cutaneous symptoms—pruriginous exanthemata, with coryza and blepharitis,—or to nervous symptoms—cephalgia, vertigo, muscular pains, genic excitation, etc. The author thinks that the vanilla factories should be under governmental supervision, both as to the hygiene of the factories and as to the selection of the workmen.

**State Supply of Diphtheria-Antitoxin.**—Under date of March 25, the Massachusetts State Board of Health announces that it has prepared a supply of antitoxin for the benefit, primarily, of such communities in the State as find it difficult or impracticable for any reason to supply themselves with the new agent from reliable sources. The Board does not propose to offer it for sale, but its gratuitous distribution will be under strict surveillance, designed to prevent waste and produce the most beneficial results. There is also pending a bill in the Illinois State Legislature providing for an appropriation of \$25,000 to enable the State Board of Health to engage in the production of the antitoxin. Until each State is prepared to supply guaranteed vaccine—an agent whose value has been proved by almost a century's experience—it is doubtful how far this new departure may wisely be carried. The *JOURNAL* is quite clear, however, as to the propriety and wisdom of State supervision over the production and distribution of both these agents.

**High February Death Rate.**—There was a phenomenal increase in mortality from acute lung diseases in many sections of the country during the month of February, 1895, as compared with the mortality from the same diseases for the corresponding month of 1894. In Chicago there were 444 deaths from pneumonia, 226 from bronchitis and 61 from influenza as against 118, 74 and 7 for the previous year; the totals for the group were 731 and 199 respectively—an increase of more than 267 per cent. February, 1895. The *Bulletin* of the New York State Board of Health also shows an increase, but not so marked, for that State. There were 10,751 deaths reported during the month, which is about 1,400 more deaths than occurred in the same month in 1894; an increase of about 15 per cent. The *Bulletin* shows that the febrile or zymotic diseases have lower death rates except whooping cough and typhoid fever; the increase of the latter disease being confined to the Hudson Valley districts, where there was an unseasonable prevalence, especially in Albany. Smallpox

caused 5 deaths—52 in February, 1894—4 in New York and 1 in Brooklyn; it does not exist in the State outside of the metropolis. Consumption caused 1,150 deaths, which is excessive for the month and is due to the influenza epidemic which has increased its mortality.

**Morbidity in Austro-Hungary.**—From official figures just published, the *Bulletin Medical* is able to give details of the infectious diseases in Austro-Hungary in 1892 and 1893. Variola has become rarer; the number of cases is 60 per cent. less than in 1889, when they numbered more than 50,000; the deaths decreased from 8,385 to 3,735—or more than 50 per cent. This good result is due to more frequent vaccinations and re-vaccinations. The mortality for vaccinated patients with variola was one-half of 1 per cent. per 1000 of the population; for non-vaccinated one-third. Scarlatina has since then increased and the same is true of diphtheritic croup. Measles is a little less common and seems more benign. Typhoid fever is more common, or perhaps it is reported more often; it causes about 15 per cent. of the morbidity. Typhus and dysentery have become rare. Puerperal fever is more frequent and has been fatal in more than half the cases reported. The same official report shows that at the end of 1893 there were in the Empire 6,728 physicians, 1,421 surgeons and 8,149 other persons engaged in the healing art. The number of physicians increased 163 and the number of surgeons decreased 111 from the figures of the preceding year. The number of midwives is increasing. At the end of the year mentioned there were 17,810 engaged in practice.

**Condensed Milk.**—It is decidedly refreshing in these days of sanitary scares and sensations to meet with such a common-sense and encouraging utterance as that of Prof. Albert Leeds, chemist of the Stevens Institute of Technology, on the subject of condensed milk. In consequence of sundry sensational newspaper items on the subject, published last summer, the Professor was requested by the New Jersey State Board of Health, and by some local boards, to investigate the various brands—some fifteen in all—of condensed milk in the market, and his report is now made public in the current number of the *American Journal of the Medical Sciences*. As was to be expected, some of the specimens were condemned—more particularly those which had undergone changes due to specific bacterial ferments getting into the milk before the process of condensation. But instead of making these the theme of a general hysterical condemnation of all condensed milk, the analyst sensibly points out that the interests of the public coincide with those of the manufacturers in most respects, and that, apart from the propriety of its use for infant nutrition, much can be said in praise of the great value of condensed milk as a manufactured product. He says that it would be a great loss to the canners were they to use or purchase watered milk, since the chief expense of the condensation is in the evaporation of the water; and dairymen dishonest enough to water milk are those most likely to have impure wells, improper food and unclean surroundings. Not from added water, but from water used in washing utensils is danger to be dreaded, and the same remark is true of the original milk itself. It is out of the question, Professor Leeds says, for a canner to employ a bacteriologist to examine the milk used, and the hardening and putrefactive changes which the condensed milk sometimes undergoes are usually due to failures in cleanliness, etc., at the dairy. Later on the canner will participate with the public in the great benefits of a rigid system of inspection that will, first of all, begin with the dairy and the cattle themselves. The *JOURNAL* is aware that, as a result of municipal milk inspection in many large cities, the dealers themselves are the most efficient agents in keeping the producer up to the mark. They not alone have frequent

analysis of their supplies made by the municipal analysts, but many dealers employ appliances for milk analysis in their own depots, and are thus enabled to detect promptly the grosser forms of adulteration and to locate the responsibility.

**Health Reports.**—Sanitary reports received by the Supervising Surgeon-General of the Marine-Hospital Service:

**SMALLPOX—UNITED STATES.**

Illinois: Chicago, month of February, 95 cases, 29 deaths; March 1 to 27, 67 cases, 31 deaths.

Kentucky: Paducah, March 24, 1 case of smallpox taken from Str. Joe Fowler; from Evansville, Ky.

Michigan: Watson Township, March 13, 1 case; Ypsilanti, March 13, 1 case.

New Jersey: Jersey City, March 27, 1 case.

Pennsylvania: Pittsburg, March 27, 1 case taken from cars en route from Cincinnati to Baltimore.

Tennessee: Memphis, March 24, 1 case reported at the U. S. Marine-Hospital.

West Virginia: Wheeling, March 27, 2 cases.

**SMALLPOX—FOREIGN.**

Arabia: Aden, February 9 to 23, 6 cases, 1 death.

Belgium: Brussels, March 2 to 9, 2 deaths.

Brazil: Rio de Janeiro, February 23 to March 2, 5 deaths.

Cuba: Havana, March 1 to 27, 1 death.

Egypt: Alexandria, February 19 to 25, 1 death.

England: Leeds, March 9 to 16, 2 cases.

India: Calcutta, February 9 to 16, 73 deaths.

Italy: Trapani, under date of March 8, 1895, the United States Consul at Palermo, reported an outbreak of smallpox at Trapani.

Mexico: Nogales, March 16 to 23, 2 cases.

Netherlands: Rotterdam, March 9 to 16, 10 cases, 4 deaths.

Russia: Batoom, February 26 to March 5, 8 cases, 4 deaths; Odessa, March 2 to 9, 3 cases, 2 deaths.

Switzerland: Basel, March 2 to 9, 7 cases.

Uruguay: Montevideo, January 12 to 23, 7 cases.

**CHOLERA—FOREIGN.**

India: Calcutta, February 9 to 16, 39 deaths; Madras, February 15 to 22, 1 death.

**YELLOW FEVER—FOREIGN.**

Brazil: Rio de Janeiro, February 23 to March 2, 8 deaths.

Cuba: Havana, March 14 to 21, 5 cases, 1 death.

Mexico: Vera Cruz, March 14 to 21, 1 death.

RIO DE JANEIRO, March 5, 1895.

I have the honor to transmit report for week ended March 2, 1895.

There were 19 deaths from *accessio pernicioso*, an increase of 14; 8 from yellow fever, the same as in the foregoing week; 5 from smallpox, a decrease of 2; 7 from beriberi, none in the last week; 1 from enteric fever, a decrease of 4; none from cholera, 1 in the previous week; 7 from diarrhea, suspected to be cholera, as against 3 in the former week, which were given with various equivalent names. There were 335 deaths from all causes, being an increase of 39, and the largest number during any week in this season. This was to be expected, as we are just at the time of greatest mortality of the year, and when there is an epidemic of yellow fever it is always at its greatest in the first week in March.

Yellow fever: I think we may safely consider that there will be no epidemic of this disease this year, as the cool season is very near, and whenever there has been no great number of cases of this disease up to this time, it has never appeared to any great extent.

Cholera: I have heard of only one suspected case during the week, which was removed to Jurijuba Bay, and the usual disinfection practiced. Along the line of the Parahyba River to its mouth a little beyond Campos, the disease appears to be finishing. In the city of Campos they say it is extinct. But it has appeared in some intensity to the north of that river in the State of Espirito Santo, and is moving slowly northward. In Cachoeira in this State, from February 24 to March 3, there were 40 cases, 21 deaths. In the village of Itapemerim there were 50 cases and only 2 deaths in the same time. The reports of 20 cases in the hospital of the Insane Asylum here in Rio de Janeiro were false, as I was informed by Dr. Carvalho Bulhões of the Health Department of the Government.

Beriberi: This disease always appears more or less toward the end of summer, which may account for the 7 deaths from it during the week.

Smallpox: This disease is continuing, though in small number, during the whole summer, an unusual occurrence; I hope it does not foreshadow an epidemic during the approaching winter season.

R. CLEARY, M.D., Sanitary Inspector, M-H. S.

## ASSOCIATION NEWS.

### The Baltimore Meeting.

#### EXCURSION TO GETTYSBURG BATTLEFIELD AND PEN MAR.

In compliance with a widely-expressed desire on the part of members of the ASSOCIATION to visit the historic battle ground of Gettysburg, the Committee on Transportation has arranged for a special excursion train to that place on the fourth day of the meeting of the ASSOCIATION. The Western Maryland Railroad will furnish a fast express train for this excursion at the rate of \$1 per passenger, provided 150 persons desire to take the trip. Notice should be given at the registration office on the first day of the session.

GEORGE H. ROHE, Assistant Secretary.

**American Medical Association—Section on Dermatology and Syphilography.**—Address of the Chairman, Alfred E. Regensburger, San Francisco, Cal.

Cerebral Syphilis, by Frank P. Norbury, Jacksonville, Ill.

Conceptional Syphilis, by David H. Rand, Portland, Oregon.

Syphilis and Gonorrhea as an Etiologic Factor in Diseases of Women, by H. R. Holmes, Portland, Oregon.

Hereditary Syphilis, by G. S. Stein, Columbus, Ohio.

Early Constitutional Treatment of Syphilis, and a few remarks on Local Treatment of Primary Stage, by W. F. Breakey, Ann Arbor, Mich.

Those who have promised papers, but subjects not named are, Drs. Edward Martin, Philadelphia, Pa.; James Nevins Hyde, Chicago, Ill.; James E. White, Boston, Mass.; W. A. Hardaway, St. Louis, Mo.; R. W. Bishop, Chicago, Ill.; W. T. Corlett, Cleveland, Ohio, and Louis Frank, Milwaukee, Wis.

Alfred E. Regensburger, San Francisco, Chairman; David H. Rand, Portland, Oregon, Secretary. Executive Committee: L. Duncan Bulkley, New York; Louis A. Duhring, Philadelphia, Pa.; A. H. Ohmann-Dumesnil, St. Louis.

DAVID H. RAND, Secretary, Portland, Oregon.

## SOCIETY NEWS.

**Medical Association of Missouri.**—The thirty-eighth annual session of the Medical Association of Missouri will be held in Hannibal, beginning Tuesday, May 21, and continuing three days. In order that the program may be arranged and printed and distributed throughout the State a week or

ten days before the meeting, we ask and insist that you send the title of your paper to John H. Duncan, room 409, Union Trust Building, St. Louis, Mo., on or before May 1, 1895. Those who desire to read papers will bear in mind that the title of their paper must accompany the name of the essayist, and that they must be in the hands of the committee before May 1 in order to get a place upon the program.

J. C. MULHALL,  
A. L. FULTON,  
J. H. DUNCAN,

Committee on Scientific Communications.

**Medical Society of the State of Pennsylvania.**—The forty-fifth annual meeting will be held in Chambersburg, on Tuesday, Wednesday, Thursday and Friday, May 21, 22, 23 and 24, 1895, beginning on Tuesday, May 21, at 9 A.M.

Address on Practice of Medicine, by I. C. Gable, York.

Address on Surgery, by C. L. Stevens, Athens.

Address on Obstetrics, by W. B. Ulrich, Chester.

Address on Mental Disorders, by F. X. Dercum, Philadelphia.

Address on Otology, by L. H. Taylor, Wilkes-Barre.

Address on Hygiene, by Hildegard N. Longsdorf, Dickinson.

Report of Committee on Contagious Ophthalmia, by J. A. Lippincott, Pittsburg, Chairman.

Report of Committee on Pharmacy, by Adolph Koenig, Pittsburg, Chairman.

Report of the Legislative Committee, by I. C. Gable, York, Chairman.

Report of the Committee on Increase of Membership, by C. L. Stevens, Athens, Chairman.

Report of Committee on Rush Monument Fund, by W. Murray Weidman, Reading, Chairman.

Report from the State Board of Medical Examiners.

WM. B. ATKINSON, Permanent Secretary.

## NECROLOGY.

**WILLIAM S. W. RUSCHENBERGER, M.D.,** Medical Director on the retired list with relative rank of Commodore of the United States Navy, died at his home in Philadelphia, March 24, 1895, in the eighty-eighth year of his age. He was born in Cumberland County, New Jersey, Sept. 4, 1807. Entered the Navy as Surgeon's Mate in 1826 and the Medical Department of the University of Pennsylvania under the preceptorship of Prof. Nathaniel Chapman and J. P. Hopkinson, and received his degree in 1830. He was appointed Surgeon to the East India Squadron and served in that capacity for two years, during which time he circumnavigated the globe. He was made Superintendent of the United States Naval Hospital at Brooklyn. He is credited with organizing the first medical bureau and laboratory for supplying the Service with unadulterated drugs. He was Fleet Surgeon of the Pacific Squadron from 1847 to 1850, and of the Mediterranean Squadron from 1860 to 1861, serving between cruises at the Naval Hospital in Philadelphia. During the Civil War Dr. Ruschenberger was stationed at the Boston Navy Yard, where he rendered efficient service. After the war he returned to Philadelphia. From 1866 to the date of his retirement, Sept. 4, 1869, he was the senior officer in the Medical Corps, and March 3, 1871, he was commissioned Medical Director on the retired list, with the relative rank of Commodore. Dr. Ruschenberger has been a prominent figure in medical and scientific circles for many years. He was President of the Academy of Natural Sciences from 1869 until 1885, when he was succeeded by Prof. Joseph Leidy. He continued to serve as one of the Curators until his death. He became a Fellow of the College of Physicians in 1838, and subsequently served for several years as Secretary, and was elected President in 1879, succeeding Dr. George B. Wood, and in turn was succeeded by Dr. Alfred Stillé in 1883. He was sent as a delegate to the AMERICAN MEDICAL ASSOCIATION in 1847, at a time when the College had a representation in the National organization. He was also a member of the American Philosophical Society and of the Historical Society of Pennsylvania. As chairman of the building committee of the Academy he rendered for five years most important service in carrying out the plan for

WM. S. W. RUSCHENBERGER, M.D.

the erection of the present hall, and was one of the distinguished orators on the occasion of the laying of the cornerstone. He wrote a history of the Academy in 1852, and the report of his scientific observations on his cruises were published in popular form, among which are "Three Years in the Pacific," "A Voyage Around the World," "Elements of Natural History," "Notes and Commentaries during a Voyage to Brazil and China," "Lexicon of Terms Used in Natural History." He also wrote an obituary notice of Samuel George Norton, M.D., and other contributors to the proceedings of the organizations of which he was a highly honored member. He wrote a report on U.S. Marine-Hospitals which appears in the first volume of Transactions of this Association.

**JAMES RIDLEY TAYLOR, M.D.,** of New York City, died March 24, aged 75 years. He was a native of Scotland, but was brought to this country at an early age. He was 54 years of age when he took his medical degree at Bellevue Hospital Medical College. He had in his first half century given rein to his talent for invention, and this in the direction of mechanical pursuits. He made a fortune in this line. Then while his two sons were qualifying themselves for practice he himself took up the study of medicine, and straightway went to the front as a surgeon. He was for six years a lecturer on clinical surgery at his alma mater. He was a member of the County Society, the Physicians Mutual Aid Association, the Medical Union, the Academy of Medicine, and of the "Old Guard" militia organization, which sent representatives at the time of interment at Woodlawn Cemetery.

## MISCELLANY.

**Asylums for the Inebriate Insane.**—Within a very few years the inebriate-insane class in France has increased from 11 to 16 per cent., according to *L'Union Medicale*, and until recently no provision has been made for them save in the regular insane asylums. Owing to a campaign inaugurated by Dr. Magnan, of the St. Anne Asylum, and Drs. Deschamps and Dubois, Municipal Counsellors of Paris, the Council of the Seine has decided to build an asylum for the inebriate insane. It will cost \$840,000, will accommodate 500 men and 200 women, and is expected to be finished in the course of the present year.

**Endoscopy of the Urethra.**—Grünfeld announces in the *Bulletin Medical* that endoscopic examination of the prostatic urethra reveals some peculiarities. If the instrument be introduced up to this region and the patient be asked to contract the levator ani, as at the end of defecation, it will be noticed that the posterior urethra is drawn back from six to fifteen millimeters. This facilitates examination of the verumont anum and the neighboring mucous membrane. This means of examination may be compared to that used in laryngoscopy, where the patient is told to utter sounds, so as to allow inspection of the vocal cords.

**Roosevelt Hospital, New York.**—The Twenty-third Annual Report is a neatly illustrated pamphlet. One of the cuts shows the new amphitheater with a surgical clinic about to take place. The death rate for 1894 was about 120 per 1,000, or deducting the cases admitted moribund, less than 90 per 1,000. The total number of days of hospital treatment was 56,500, and average per diem cost per capita \$1.97, but deducting out-patient work, the in-patient cost was \$1.74 per diem, of which 26 cents was for food. The number of hospital attendants was 124; average daily patient population 155; showing an apparent inflation of the paid service departments. There were ambulance calls to the number of 1,642. The accident room treatment included 5,019 cases that did not need the regular hospital ward care, but received relief without taxing the accommodations of the hospital in the regular way. This department of the work has so far increased that it is proposed to make an addition for that object and for a Nurses' Home, that should cost not less than \$150,000; enlarged quarters for private patients will also enter into this plan.

**Diphtheritic Conjunctivitis Treated by Serotherapy.**—Dr. Jessup recently communicated a report to the Royal Ophthalmological Society of two cases of diphtheritic conjunctivitis treated by Klein's antitoxin. The first case was that of a boy, aged 19 months, with false membrane on the conjunctivæ of both eyelids of the left eye, with a patch on the uvula, swelling of the sub-parotid lymph glands and albuminuria. Three injections were made; the total quantity of the antitoxin used was three grams. The membrane disappeared in five days without leaving any trace on the conjunctivæ, though the only local application used was distilled water. In the second patient, also a boy aged 8 months, there were membranes on the palpebral conjunctivæ of both eyes, enlarged glands and a muco-purulent discharge from the nostrils. Two grams of the antitoxin were used in two injections and the false membrane disappeared in four days. Hayward examined the membranes in both cases and discovered large quantities of the Löffler bacillus. In his opinion the cure was certainly due to the antitoxin, because these cases are generally accompanied with purulent ophthalmia and ocular lesions which are very slow in healing. Coppey, of Brussels, has also reported a case in a little girl of 1 year, with severe ocular diphtheria cured in four days after one injection of Behring's serum.

**The Philadelphia County Medical Society.**—We print herewith a circular which is being industriously circulated by the Philadelphia County Medical Society. We make no comment on the kind of tactics which seeks to have other societies act on an *ex parte* statement; but we venture to remind our brethren in other societies that this matter is one which must be settled by the AMERICAN MEDICAL ASSOCIATION. The JOURNAL has taken no editorial part in this matter, but it can not help noticing that not the slightest commendation is given for any of the many changes that have taken place in the JOURNAL within the year, nor is any hint or suggestion given, of how the JOURNAL is to be supported if its advertising is cut off.

There are two direct mis-statements in the committee's report which we are sure they will be pleased to have corrected; one is that the decision of the Judicial Council was "not given to them or published." We notice that Dr. John

B. Roberts has signed this document, and that he was also the Secretary of the Judicial Council. If he failed to notify his associates on the committee of the action of the Council, surely the JOURNAL is not to blame. In the matter of the Stock Sanatorium, that advertisement was inserted *once* by inadvertence of a clerk, and afterward suppressed. In the matter of Labordine, it will be seen by reference to its advertisement, that the *formula is published* each insertion. It is therefore not a *secret* preparation.

The present management has acted according to its best judgment for the interest of the Association, and as the Trustees are personally liable for the expenses of the publication (the Association having so far refused to become incorporated) they would naturally be much pleased to have some of the critics point out a way to support the JOURNAL. They *assume* that the critics mentioned are friends of the JOURNAL, but the evidence is not overwhelming that the persons behind the movement are not really inimical, and would not rather have it die than live. They at least are remarkably careful not to commend the JOURNAL in any way, nor have these persons ever commended it since its establishment, when the proposition of a certain Philadelphia publisher to publish the JOURNAL was rejected.

These warlike preparations seem to us altogether unnecessary. If our dear friends really wish to see the JOURNAL independent of any particular class of advertising matter, will they kindly point out the best means of supporting the JOURNAL without receipts from advertising, and exactly how much they are willing to contribute to that support? The Trustees are ready to receive suggestions on this point, as they have not up to this time quite understood how to go on building up and enlarging the JOURNAL while depriving it of the revenue accepted by other journals recognized as reputable throughout the world. The JOURNAL has in fact declined a great many of the advertisements offered, when the formula was refused.

Seriously, the question arises, Will the profession support the JOURNAL in such a step? Will they contribute more freely? These are points that any sound business committee would want to have settled before they accede to any very radical departure from existing methods that at present are universal in medical journalism.

#### PHILADELPHIA COUNTY MEDICAL SOCIETY.

James C. Wilson, M.D., President; T. B. Schneideman, M.D., Secretary.

N. E. Cor. THIRTEENTH AND LOCUST STREETS, Philadelphia, Pa.

*Dear Doctor:*—As a member of a constituent society represented in the AMERICAN MEDICAL ASSOCIATION, your attention is asked to a matter in which every such member has a measure of personal responsibility. You will find the history and present status of the question at issue set forth in the annexed report of the delegates of the Philadelphia County Medical Society made on their return from the last meeting of the AMERICAN MEDICAL ASSOCIATION, held in San Francisco in 1894. In this connection we would call your attention to the following salient points:

1. The Code of Ethics—the moral and organic law of the AMERICAN MEDICAL ASSOCIATION—as is well known, not only prohibits physicians from employing secret nostrums, but declares that "in any way to promote the use" of such nostrums is reprehensible.

2. The advertising of such nostrums in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, which is taking place, is certainly an attempt to promote their use. The Association appears, therefore, at least tacitly to permit the Editor and Trustees of its official journal to transgress, in the conduct of the JOURNAL, the law laid down for our guidance as physicians.

3. The attention of the Association having been called to the inconsistency of its course in this regard, resolutions were unanimously adopted at the Detroit (1892) meeting, instructing the Trustees of the JOURNAL in future to respect this prohibition of the Code in the discharge of their trust.

4. Thereupon the Trustees appear to have evaded this command by adopting as their governing policy the rule "that an advertisement of a proprietary medicine shall be accepted in the discretion of the Committee when the proprietors thereof shall furnish the complete formula." The advertisement of secret nostrums in the JOURNAL continuing, the Trustees have, presumably, become accessory to the secrecy, inasmuch as complete formulae of the preparations referred to are not published. Plainly, persistence in the present course results in an abrogation by indirection of a fundamental provision of the Code, which should either be strictly enforced or frankly repealed.

The contention of the Trustees that without the income derived from this particular class of advertisements a deficit would result, does not in any way meet the ethical issue; nor does the precedent of other journals, including the organ of the British Medical Association, furnish a justification for the course adopted.

The question under consideration is not one of money but of morals; the AMERICAN MEDICAL ASSOCIATION can not afford to sell its honor under any circumstances or for any price. But would not the apparent financial sacrifice entailed by an honest and hearty observance of the spirit and letter of the Code of Ethics in the conduct of its journal be

## LECTURES.

### LECTURES ON INTRACRANIAL SURGERY.

#### IV—ABSCESS OF THE BRAIN.

BY EMORY LANPHEAR, M.D., PH.D.

ST. LOUIS, MO.

Suppuration in the brain does not differ from abscess in other parts of the body, except in the symptoms which arise from the peculiar location of the pus. Formerly, abscess of the brain and cerebral softening were regarded as synonymous terms; but now we know that softening is the result of the death of brain tissue from interference with the blood supply—a purely passive process, the creamy mass possessing none of the characteristics of pus excepting the resemblance in consistency and color; on the other hand, abscess is the result of an active process, inflammation, and in the broken-down tissues are found the distinctive microorganisms of true pus, and the same rule for the treatment holds good as in abscess elsewhere; let the pus out as soon as its location can be determined.

#### MORTALITY.

Abscess of the brain, from a surgical standpoint, is more favorable than almost any other form of cerebral disease. The rule is therefore to operate always; and as early as possible. Death is certain without surgical interference—relief is sure if operation be not too long delayed. The mortality after operation is very slight—about 17 per cent. according to von Bergmann—as compared with a death rate of 100 per cent. without it.

#### ORIGIN OF ABSCESS.

Cerebral abscess is never idiopathic. It always come from infection, the sources of which are three in number:

1. *Trauma*.—It may originate from blows or falls upon the head, even when the skin has not been injured nor the bone fractured; though often a punctured or other fracture has been present, in which cases it is usually associated with meningitis. Following trauma the suppuration may be either diffuse (acute meningitis and cerebritis running on to pus formation and proving fatal within a few days) or circumscribed, the area of red, or inflammatory, softening growing more and more liquid in its center until it becomes simply a collection of pus. In this instance the pyogenic cocci may reach the injured tissue by direct infection through a wound on the one hand or through the circulation on the other.

2. *Embolism*.—The abscess may be due to impaction of pyogenic emboli from some distant focus of suppuration (as the lungs, especially gangrene, bronchiectasis and fetid bronchitis; ulcerative endocarditis; empyema, etc.); in which case it will probably be located near some terminal twig of the middle cerebral artery, especially the left.

3. *Infection by Direct Continuity of Structures*.—But most frequently intracranial suppuration is traceable to purulent inflammation near by, as from injury or disease of the bone. Of the latter we see a typical case in abscess accompanying inflammation of the mastoid cells and in otitis media suppurativa; here the pus microbes find an entrance from the neighboring focus—and the same is true in abscess of the anterior lobes where caries of the ethmoid is the primary trouble.

The method of extension is thus described by Moullin: (2d edition, p. 666).

"In many instances the inflammation spreads by direct continuity of structures, the bone first becoming inflamed and necrosed; the dura over it sloughs, and either the pus spreads into or through the arachnoid space at once, or the membranes become glued to each other and to the cortex by a protective inflammatory exudation before this can occur. There are, however, other routes almost as direct along which the infection may travel. It may spread down the internal auditory meatus, or through the hiatus Fallopii, or the aqueductus vestibuli, or it may extend along some of the numerous small veins (each surrounded by a peri-vascular lymph-sheath) which run between the middle and internal ear on the one hand and the dura and pia on the other. Some of these pass directly from the temporo-sphenoidal lobe to the dura covering the petrous portion of the temporal bone; others run through the squamo-petrous suture and through the slit in the dura that lies by the side of the aqueductus vestibuli; others again lie in the small canals which connect the middle ear directly with the middle fossa of the skull; and not a few communicate with the middle meningeal veins and the superior petrosal and lateral sinuses."

The only unexplainable phenomenon connected with the formation of cerebral abscess has been brought to notice by Senn, viz., how the staphylococcus pyogenes aureus (or albus) which elsewhere causes only circumscribed suppuration, and which is the peculiar pus organism of otitis media and of suppurative osteomyelitis of the ethmoid or other bones, may in some cases be the exciting factor of a diffuse, septic leptomeningitis such as would result from infection with the streptococcus pyogenes or the streptococcus of Fehleisen—the suppurative meningitis following erysipelas.

#### LOCATION.

But whatever the cause, since intracranial suppuration is invariably fatal if left to itself, the indications are always 1, to locate the affected point and 2, to open the skull, evacuate the pus, irrigate the abscess-cavity and establish free drainage. So essential to success is this rule that when the dura is opened over the supposed seat of the abscess and no pus is found, it is advisable to thrust an aspirating needle into the brain in various directions until the

pus is located; that is, in cases of supposed abscess following injury or infection from a distant focus. I have often used a large needle in this way (even withdrawing some of the fluid from the ventricles) without apparent harm to the brain.

Great care must, however, be taken not to practice this extensive exploratory work in those doubtful cases which, instead of being cerebral abscess are thrombosis of the lateral sinus or pyemia from middle ear disease—cases which closely simulate abscess of the brain in their clinical picture. When the diagnosis is not certain the mastoid antrum must be first explored and free communication established with the external auditory meatus; by this procedure many cases of meningitis might be averted. But—in cases presumed to depend upon suppurative otitis media—if no pus is found in this preliminary operation, exploratory trephining should be practiced; the points of selection being a little above and somewhat behind the meatus (to expose the anterior surface of the petrous bone) or just behind the meatus and on the same level.

It is best, perhaps, to first examine the orifice of the mastoid vein, and if no evidence of thrombosis be found, to then make the opening in front, exposing the under surface of the temporo-sphenoidal lobe. The reason for this advice is that 95 per cent. of cerebral abscesses occur within a circle of an inch radius, the center of which is a point one and one-half inches above and one and one-fourth inches behind the center of the meatus auditorius externus. Rarely abscess is found in the anterior lobes or the cerebellum.

The pus may be, as regards the skull:

1. Subcranial—between the bones and dura;
2. Subdural—among the meninges;
3. Subcortical—in the substance of the brain.

#### SYMPTOMS.

The symptoms of cerebral abscess vary according to the rapidity of development and location of the point of suppuration. Very rarely the trouble is ushered in by a rigor and high fever, succeeded by delirium, vomiting, headache and other symptoms of acute meningo-encephalitis; this is what is called acute abscess, and follows injury or operation. Usually the symptoms are quite slow in making their appearance, as certain parts of the brain (like the apex of the temporal lobe, a favorite site of abscess) may for long contain an abscess of considerable size with no special symptoms to direct attention to its existence, the disease being suspected only when it begins to encroach upon more important structures either by pressure or direct irritation. When thus far advanced there will be found a subnormal temperature for a part of the day in most cases, together with more or less headache, and irregular fever.

In cases dependent upon traumatism there is commonly a latent period after the injury. This may, in rare instances, be as short as two weeks, but is generally much longer, even years occasionally elapsing before the disease causes trouble. In this period the patient is likely to become cachectic, more or less loss of memory accompanying the decline in bodily health, though the head symptoms may be so slight or so gradual in their development as to escape notice. Head pain is almost always present and may be quite intense; but I have operated upon one case of abscess of large dimensions (fully one-half

of the hemisphere) where no pain whatever was ever felt; the location of the pain does not necessarily correspond to the situation of the abscess. The headache may be either general or local. Optic neuritis is a quite frequent accompaniment and the pupil upon the affected side may be dilated or fixed.

Only too often localizing symptoms are not present, and so when headache, drowsiness or partial paralysis make their appearance some time after an injury or during the progress of long-continued middle ear disease, the surgeon is compelled to resort to exploratory measures, operating in the one instance at the point of trauma (though abscess may really be far distant) and in the other at the point of selection already described. As a rule, it may be said that the chief evidences of abscess are subnormal temperature, irregularity of the pupils, and a dull, sluggish condition of the mental faculties, possibly diversified by unexplainable fits of irritability, with more or less headache, either localized or diffuse.

Ptosis, fixed mydriasis or paralysis of the ocular muscles indicate the temporo-sphenoidal lobe as the location of the abscess; and it is not at all unusual for more or less paralysis of the arm and face to be present from compression of the lower motor centers which are close by; with aphasia if in the left hemisphere. Hemianopia and occipital headache are the chief signs of abscess in the hind-brain.

When the abscess is located in the cerebellum, vomiting is added to the other symptoms; and when the middle lobe is affected, staggering (cerebellar incoördination) is also present usually. Abscess of the cerebellum is so uniformly due to middle ear disease that when suspicion of abscess exists in the history of a case of otitis media and trephining does not reveal the pus in the temporo-sphenoidal lobe, the surgeon should open the skull over the cerebellum and explore for abscess in this region.

#### DIAGNOSIS.

These symptoms occurring weeks, months or years after severe injury to the head, or following a chronic discharge from the ear, are sufficiently prominent to enable the surgeon to make a diagnosis; or at least to give him enough assurance of the probable existence of pus within the cranium to justify exploratory trephining. Nor is a localizing symptom necessary to determine the situation of the abscess in the majority of cases; the operator may here well rely upon his knowledge of the pathology of the disease and the surgical anatomy of the part involved. In every suspicious case the patient should be given the benefit of the doubt; and here, if anywhere, the surgeon is to be commended for being positive in his demand for operation and prompt in carrying conviction into effect.

Certain kinds of tumor resemble abscess in their clinical picture, but choked disc will be found present almost invariably in tumor, while it is not a frequent symptom in abscess. Besides, in tumor the absence of a cause of abscess may be regarded as highly important from a diagnostic standpoint. And last—subnormal temperature alternating with an irregular febrile record will not be found in tumor; but may be absent in abscess as well.

Pus in the mastoid antrum may give rise to all the symptoms of abscess (even optic neuritis) but there are generally some local signs that point to the osteal

disease. In case of doubt one should open the mastoid before trephining.

Thrombosis of the lateral sinus is quite similar in a general way but a chill precedes the other symptoms; the pain is located at the point affected; and a stiff neck, retracted head and tenderness or edema over the mastoid will assist in differentiating. Later, pyemia occurs. If doubtful between thrombosis and abscess the mastoid vein may be exposed before trephining; if active the sinus is not clogged.

The transition from a chronic to an acute abscess may be sudden from a blow upon the ear or head (as in the case of Mr. D., of which I will soon speak) or from exposure to cold and wet; and should not interfere with a proper diagnosis being made.

Cerebellar abscess is almost beyond the possibility of positive diagnosis; the symptoms being very indefinite. Severe occipital headache, persistent vomiting and retraction of the neck, with irregular variations in the temperature are suggestive of disease of the cerebellar hemisphere; and when arising in connection with ear disease are enough to warrant exploration.

#### OPERATION.

It is frequently necessary, as will be evident from the preceding remarks, to make exploratory trephining; which here is certainly justifiable. If the abscess is not found at the seat of injury in traumatic cases, if the brain project into the opening and is pulseless, there can be little doubt as to the existence of an abscess somewhere and, an aspirating needle must be inserted in various directions until the pus is found; in so using the needle the point must never be moved from one part of the brain to another without withdrawal, as important fibers would be injured; but by taking the needle clear out of the brain tissue and re-inserting it with the point guided in the desired direction little permanent injury can be caused.

In cases of middle ear disease the scalp is retracted as a large flap including the pericranium, and the trephine applied at the point already indicated, viz., one and one-half inches above and one and one-fourth inches behind the center of the external auditory meatus; if nothing is found on reaching the dura, the latter is opened and exploration made.

Moullin very properly says if no abscess is found in this anterior operation, either between the dura mater and the bone or in the substance of the brain, and there is no evidence of thrombosis of the lateral sinus even when the orifice of the mastoid bone is exposed the surgeon should not hesitate to extend his exploration, even at the risk of being called hazardous, but should separate the periosteum and muscular attachments from the occipital bone beneath the superior curved line and open the skull so as to explore the lateral lobe of the cerebellum. In many cases of cerebellar abscess, however, there is sinus thrombosis as well, and there must consequently be some danger of the one being overlooked when the other is found—so it is best to search for both in every suspicious case. If extra-dural abscess or thrombosis of the lateral sinus be found, the jugular vein must be at once tied to prevent *débris* getting into the circulation, as the only hope of saving life lies in thoroughly cleaning out the clot and removing the whole focus of the disease. (Operation for thrombosis of the lateral sinus will be considered more in detail in a subsequent lecture.)

When the abscess cavity has been located, a free incision must be made into it to obtain thorough drainage. Then, for the only time in cerebral surgery, an antiseptic solution may be employed; in every other operation a normal salt solution being used for irrigation, etc., after the point of exposing the dura has been passed. In abscess, however, the cavity should be thoroughly washed out with hydrogen dioxid followed by a solution of bichlorid of mercury, 1 to 2,000. A large rubber drainage tube is then introduced and the wound in the scalp closed with silkworm gut sutures except at the point of drainage. It is perhaps well to dust in a considerable quantity of iodoform or other drying antiseptic powder, before closing the scalp. Very great care is exercised in dressing, fresh sublimate gauze being applied in abundance, as further infection from without must be avoided.

The drainage tube is washed out twice daily for a time, especially if it becomes clogged; later, once daily is sufficiently often to dress the wound. Day by day as the wound fills with granulation tissue the tube must be drawn farther and farther out, care being taken not to let the external wound heal too speedily. Usually from two to three weeks will be required for the abscess to stop discharging.

During the operation the most scrupulous care is to be taken as to asepsis. The scalp must have been thoroughly scrubbed and cleaned with alcohol or sulphuric ether and sublimate solution, and the hands of the operator and assistants disinfected by scrubbing for six to ten minutes and immersion in saturated solution of permanganate of potassium, then in strong solution of oxalic acid and finally in sublimate solution for two minutes; or in the absence of these, soaked thoroughly in alcohol and then in sublimate solution. And during the operation, if any object be touched which has not been sterilized—the table, the pulse of the patient, a chair, the pillow, etc.—the hands must be washed again in the sublimate solution before touching the wound or any instrument. These are little points, you say? No, indeed! Too many surgeons, nowadays, are too careless in these little details; and a human life may depend upon the care with which seemingly trivial acts are watched by the operator; no assistant must be for a moment beyond the eye of the surgeon, or if necessarily so be compelled to wash again. There may be no pus in the brain, and carelessness will cause infection. It is especially in redressing the wound that I would urge the greatest care. Here the surgeon says to himself: "Oh well—I have already a purulent infection, the wound is a pus-producing one, so I need not be careful." Only too often have I heard such remarks from men who should know better. There are other germs besides the staphylococcus pyogenes aureus which is found in these abscesses, and the greatest care in aseptic details must be carried out in the dressing, or there will be contamination through carelessness and death will result when recovery should have occurred.

#### CASES.

As I have already stated, abscesses are occasionally not single. Kidd reports a case of double abscess in which the trephine was used in the frontal region and pus evacuated from an abscess; the patient died on the fourth day and the post-mortem examination revealed a second and larger abscess in the temporo-sphenoidal

lobe of the right side *without* (a rarity, indeed) disease of the petrous bone; the cause of the frontal focus was a recent kick of a horse—that of the posterior abscess unknown. A case quite similar gave one of the two fatal results I have had in my own operations for abscess:

Chas. D., aged 32 years, was struck upon the right side of the head by a rapidly moving car in Kansas City, on the night of Sept. 18, 1891. He was unconscious for a little time, but recovered and went about his work next morning, though his employer noticed that he acted strangely—"dazed." This condition continued until Oct. 11, 1891, when he went to bed on account of an increasing head pain, especially marked at the junction of the parietal and occipital bones of the right side—the place of injury. He developed fever, had a severe general convulsion, repeated chills at irregular intervals and finally became delirious and semicomatose. I first saw him October 18 in consultation with his physicians, Drs. C. D. McDonald and G. E. Mosher. I advised trephining at the point of injury and also over the temporo-sphenoidal lobe of the opposite side on account of a chronic ear discharge, though there were no localizing symptoms pointing to trouble there—it was merely advice founded upon general principles. At 4 P.M. when arrangements were completed the patient was in profound collapse, the pulse intermittent and weak, extremities cold, eyes turned strongly to the left and insensible to light; operation was therefore postponed, as it was seen that death on the table would be the effect of our work.

Under stimulants, etc., he improved somewhat; and on October 25, I opened the skull at the spot injured. The dura bulged prominently into the hole and was entirely without pulsation. On turning back the dura a large area of softened brain tissue presented; which upon incision gave a considerable amount of pus. This cavity was scooped out and the surrounding red softening gently curetted with a sharp spoon, a Paquelin cantery being necessary to control the sharp hemorrhage. Palpation showed quite extensive softening anteriorly, but not broken down tissue; so it was left. After irrigation a drainage tube was inserted and the scalp closed. As the man was in extreme collapse from the bleeding, no further exploration was deemed advisable. There seemed to be quite an improvement that day in his mental and general condition though shock was profound. On the 27th we dressed the wound, finding fully an ounce and a half of pus discharged. Fresh dressings were applied and the patient made easy, but he died the next morning apparently from exhaustion.

The autopsy showed another abscess, evidently of months' standing in the left temporo-sphenoidal lobe due to caries of the petrous bone. The only ante-mortem evidence of this abscess was the chronic discharge from the middle ear with an occasional sharp pain in the occipital region of the left side.

As illustrating the fact that the abscess may be located far away from the site of injury, I quote my other fatal case from my record book:

Ed. F., carpenter, age 26, was shot by pistol, the ball entering one and a half inches to the right of the sagittal suture and two and a half inches posterior to the coronal. It emerged (or the major portion of it as afterward proved) at the sagittal suture, cutting the superior longitudinal sinus. The hemorrhage was consequently profuse and would have proved fatal had not a bystander crowded a handkerchief into the wound and applied firm pressure. Fifteen minutes after the accident, I found him upon the floor in an incredibly large pool of blood, pallid, limp and helpless but conscious and talkative. This was at 1 A.M. I packed the wounds with gauze and had him removed to the City Hospital. At 9 A.M. I opened the wound and found the bone badly shattered between the two openings which were therefore made one by the bone forceps; a portion of the bullet was found lodged between the plates of the parietal bone. All the broken-down brain tissue, amounting to a large teacupful, was trimmed away and after irrigation with water at 120 degrees, the cavity was packed with borated gauze. The patient soon regained consciousness. On the second day evidences of inflammation arose and a hemiplegia gradually developed—but upon the same side as the wound, a symptom we explained by saying it was a case in which there was no decussation of the motor fibers in the posterior pyramids. After a few days the inflammatory signs disappeared, the wound healed nicely and the thirteenth day the man was sent to his home.

He did well for a number of weeks, but the paralysis did not disappear, I thought because the motor area was destroyed. But he suddenly developed symptoms of abscess and died. The autopsy showed the cerebrum of the injured side in excellent condition; so far as any lesion here was concerned he was well. But a small fragment of the bullet pierced the falx cerebri a little above the corpus callosum and lodged in the white matter of the side opposite the injury, causing a hemorrhage just external to the corpus striatum—hence the hemiplegia of the same side as the primary injury. This clot became the seat of an abscess which, finally ruptured into the lateral ventricle, broke down the septum lucidum and caused death.

In this case the subject practically recovered from the original wound and from the operation; and the man would have been restored to his previous condition of health had not the fragment of ball caused the abscess in the opposite hemisphere. The location of the abscess I had no means of determining before death.

It has been said that abscess of the frontal region can not be diagnosticated. While this is true, there are certain cases in which we *suspect* abscess in the frontal convolutions and here exploratory operation can be made with some degree of propriety. Three patients have been under my care for frontal abscess. One case (subcortical) in which aphasia became a symptom as the disease progressed, would not consent to operation and died in the hospital; the autopsy showed the correctness of the surmise as to the location of the suppuration. The other two submitted to operation and recovered. The first I wish to report presented this history:

Dora V., of Denver, Colo., aged 28 years, prostitute, was admitted to the hospital Sept. 21, 1893. She complained of an intense severe headache, located just to the right of the middle line, two and one-half inches above the orbit; this pain began about six weeks before, and continually grew worse. Her physician regarding the case as one of gummy tumor, sent her to me for its removal, with the statement that for about ten days the mind had been seriously affected. Upon examination she appeared stupid, dull, with dilatation of the right pupil; and there was some tenderness at the point of greatest pain. Her temperature varied from 97 to 100 degrees during the next four days, so a diagnosis of abscess was made. On September 26, assisted by Drs. Thrush and Maxson, I reflected the scalp at the point supposed to be affected, and made an opening about one inch in diameter with the gouge. Upon removing the outer table there appeared evidences of bone inflammation, and when the inner table was pierced pus came welling up from within the cranium. The abscess was subdural, but adhesions everywhere had prevented general meningeal suppuration; the cavity was therefore irrigated but not curetted. Free drainage was established and the usual dressings applied. September 27 the record says: "Doing nicely, no pain, slept well, mind clearer. Temperature all day, 99.5 degrees." She continued to improve rapidly, the discharge of pus ceased on October 28, and two days later she was allowed to go. The cause is unknown, but is presumed to be syphilis probably aggravated by a blow, though no history of the latter could be obtained. All her mental symptoms vanished immediately after operation, and at last account she was still well.

The second case was subcranial. The condensed history is as follows:

Mrs. B. D., patient of Dr. J. E. Dennis, 28 years old, I saw Dec. 16, 1891, on account of severe headache of several weeks duration, which resisted every anti-neuralgic remedy, the doctor desiring operation for the relief of pressure on the brain, the symptoms certainly indicating such a condition. A careful examination failed to show any disease of the ear or the nose; the retina was slightly congested; pupils very sluggish; slight ptosis of right lid. No cause for the pain could be discovered unless it was due to tumor or abscess. There being no localizing symptom, I declined to operate; the pain, indeed, was referred always to one point, but I did not then feel that pain alone would justify exploration.

At midnight, December 18, I again saw her in consulta-

tion. The pain, she said, was unbearable—so great she would violently beat her head against the wall unless guarded. Her temperature was 100 degrees and she was delirious most of the time. On the evening of the 19th she was in a critical condition—temperature 96.5 degrees, heart action feeble and irregular, a low form of delirium still present; as death appeared inevitable I consented to trephine—upon both sides if necessary.

December, 20, at 1 A.M., I made an incision along the line of the eyebrow to the base of the nose, dissecting the tissues upward sufficiently to allow the use of a gouge. At a point about one inch above and a little internal to the orbit I opened the frontal sinus and then attacked the internal table. As soon as the chisel entered the skull, pus began to pour out and when a sufficiently large opening was made fully one and a half ounces escaped. The abscess was between the bone and dura; with the probe dead bone could be felt, believed to be necrosis of the ethmoid, so I gently curetted with the sharp spoon but hemorrhage caused me to desist. I washed out the cavity with bichlorid solution and with Marchand's peroxid of hydrogen and finally filled in with much iodoform and inserted a drainage tube.

My record for January 3 says: "The pain ceased immediately after the operation, and the general condition improved rapidly. The wound has been dressed every second day, the cavity being thoroughly irrigated with weak sublimate solution and then with hydrogen peroxid and filled with 10 per cent., iodoform emulsion, under which treatment pus has ceased discharging." The iodoform emulsion was used because I presumed the ethmoidal necrosis to be tubercular.

On January 15 the external wound was healed, but a little pus was still discharging through the nose.

I have frequently seen this patient since and there has been no further trouble from the necrosis—if there was a necrosis—and her health is perfect. There never was any evidence of syphilis in this case.

I do not give histories of cases from middle ear disease—they are too common, but as a result of my own experience, I can well counsel exploration in every case of suspected abscess of the brain; with the expectation of a favorable result in a large percentage of operations.

## ORIGINAL ARTICLES.

### THE DISEASE RESISTING POWERS OF THE BODY.

A REVIEW OF THE FOUNDATIONS OF NUCLEIN AND SERUM THERAPY.

Read before the Biological Society of Chicago University, Feb. 20, 1895.

BY CHAS. T. MCCLINTOCK, M.D., Ph.D.

UNIVERSITY OF MICHIGAN, ANN ARBOR.

When it was shown that bacteria were the cause of certain diseases, it was believed for a time, that if these bacteria by any means found an entrance into the body, disease must follow. Until quite recently, popular writers on these questions left this impression with their readers.

Pasteur noticed that in case an animal recovered from a germ-caused disease, the germs disappeared from the blood and tissues. He also observed that, in some cases at least, after an animal had recovered from the attack it was more or less immune or insusceptible to the same disease. That this immunity following one attack was true for many of the con-

tagious diseases was indeed a matter of common knowledge. Early in his investigations Pasteur noticed that some animals were readily affected by his microbes, while others were entirely immune; again, that in some cases, a young animal could be infected but not an older one. Pasteur studied these matters and worked out an explanation for them. He believed that his microbes were in some respects very delicate creatures, demanding particular kinds of foods, without which they could not grow. He noticed that in his flasks the bacteria grew for a time, then ceased growing, although a considerable amount of food remained unused. He concluded that their growth was stopped on account of the exhaustion of some essential part of the food. He noticed that other germs might grow in these flasks after one species had ceased to grow. Reasoning in this manner, he thought he saw a probable explanation for recovery and immunity. A few anthrax germs had been injected into an animal and after some hours an examination of the blood showed that each drop contained thousands of these germs, and yet a few days later, in the favorable case where the animal recovered from the disease, the blood when examined contained few, or it may be, no germs at all.

Pasteur reasoned that here the animal had served as a culture flask, and with the same result, as soon as certain things in the animal's body were exhausted the germs ceased to multiply and disappeared. On this, the "exhaustion theory," as it is called, Pasteur based his hope for preventing and curing the contagious diseases. Time will not suffice to give the details of his work on vaccines.

In brief, his method was to take an attenuated germ, one that by exposure to unfavorable conditions had been weakened and enfeebled. With a small quantity of this culture, he would then inoculate an animal. This feebly growing germ, or vaccine, would gradually and without serious harm to the animal exhaust that particular substance necessary for its growth. Having done this, the germ would die and disappear. The animal having recovered from its vaccination fever, would then be proof against an attack of the most malignant germs of that kind. The first two diseases studied by Pasteur in this way yielded brilliant results. By his method, with attenuated cultures of anthrax, and chicken cholera, he was able to make very susceptible animals wholly immune to the most virulent forms of these diseases. He concluded that the method could be universally applied, and made the remarkable statement that, "it is possible for man to eradicate every contagious disease from off the face of the earth."

Hundreds of workers attempted to apply this theory to the various bacterial diseases. Gradually it was seen that the method would give satisfactory results in but few diseases, and that the theory was a poor one.

In the same year that Pasteur's exhaustion theory was put forward, another and opposing one was advanced by Chauveau. Chauveau reasoned that bacteria ceased to grow in our flasks and test glasses, not because some particular food is exhausted, but for the same reason that a higher animal or plant when confined, is gradually poisoned by its own excretions. Whenever the excretory products of the bacteria reach a certain amount, they cease to grow, although there may be an abundance of food. It had long been known that this was true for some of the higher

plants. Pasteur himself had shown that the yeast plant ceased to grow whenever the amount of alcohol which it produced reached 15 per cent.

Chauveau explained that an animal recovered from an invasion of bacteria, if it could survive until these excretory products accumulated in such quantities as to gradually hinder and finally wholly arrest their growth. Immunity, he said, was due to the fact that these excretory bacterial products were very slowly eliminated, and as long as they remained in the body they protected it from an invasion of the germs. This theory was widely accepted and until the last two years was the most popular one. It was essentially on this theory that Koch based his attempt to cure tuberculosis with tuberculin, which is essentially an old filtered bouillon culture of the tubercle germ. So Klebs introduced diphtheridin for diphtheria.

The theory underlying these attempts at cure was to introduce into the body, those products which arrest the growth of the germ in our flasks and tubes, and by so doing to stop the growth of the germs already in the body. These attempts at cure were failures, and we now believe that they were wrong in theory.

Pasteur's facts were all right; the germs do disappear with recovery from the disease and there is generally, more or less immunity. How can we explain these things? These are all-important questions, for when we know how the body destroys disease germs then it is probable that we can discover some means with which to assist in the fight against these invaders.

"As early as 1872, Lewis and Cunningham demonstrated the fact that bacteria injected into the circulation rapidly disappear.

"In 1874, Traube and Gschiedlen found that arterial blood, taken under antiseptic precautions from a rabbit into the jugular vein of which  $1\frac{1}{2}$  c.c. of a fluid rich in putrefactive germs had been injected forty-eight hours previously, failed to undergo decomposition for months. These investigators attributed the germicidal properties of the blood to its ozonized oxygen. Similar results were obtained by Fodor and by Wysokowicz. The latter accounted for the disappearance of the germs, not by supposing that they were destroyed by the blood, but that they found lodgment in the capillaries.

"The first experiments made with extra-vascular blood were conducted by Grohmann under the direction of A. Schmidt in his researches upon the cause of coagulation. It was found that anthrax bacilli, after being kept in plasma, were less virulent, as was demonstrated by their effect upon rabbits. Grohmann supposed that in some way the bacteria were influenced by the process of coagulation.

"In 1877, Fodor made a second contribution to this subject, and in this he combatted the retention theory of Wysokowicz. One minute after the injection of 1 c.c. of anthrax culture into the jugular vein, in eight samples of blood, Fodor found only one colony of the bacillus. Then he took the blood from the heart with a sterilized pipette and added anthrax bacilli to it. This was kept at 38 degrees C., and plates made from time to time showed a rapid diminution in the number of germs; after a time, when the blood had lost its germicidal properties, the number of germs began to increase."

In 1888, Nuttall showed that defibrinated blood had this germicidal power. Since then Nissen, Behring,

Buchner, Haliburton, Hankin, Bitter, Christmas and others have worked on this question. All of these observers find that the blood, within or without the body, has germicidal powers. They find that this germicidal substance can be precipitated with alcohol, that it can be dried and when redissolved is as active as before. Prudden found that ascitic and hydrocele fluids restrain the development of certain germs. Other observers have shown that the humors of the eye have antiseptic properties. Some of the experimenters conclude that the germicidal substance is serum albumin, others that it is a globulin, while all agree that it is some proteid.

These experiments demonstrated the fact that the body had the power to kill at least some bacteria, but gave us little if any insight into how it was done. About this time, that is, in 1884, Metschnikoff brought forward an explanation that seemed plausible, and has had and still has many advocates. He believes that the white blood corpuscles together with the cells of the spleen, certain glands, and the cells lining the blood vessels have the power to take up and destroy the germs. All of these cells have the power to put out pseudopodia. It had been known for a long time that when small particles were injected into the blood, the white blood cells would pick them up and engulf them. It was also well known that when a part of the body was injured, the white blood cells flocked to the inflamed part in large numbers.

Metschnikoff concluded, that the function of these cells, which he named phagocytes, is to watch the avenues by which pathogenic germs may enter the body, and on their approach to engulf or swallow them and by a power of digestion to destroy them. The theory attracted universal attention and admiration. He also attempted to explain the migration of the white cells to a wound. He found that certain substances attracted the cells, while certain others repelled,—that they did not swallow every particle that came in their way but had a selective power—this positive and negative chemiotaxis as he calls it, is used by him to explain many of the phenomena connected with cure and immunity. He finds that certain bacteria attract and in turn are destroyed by the phagocytes while certain other more virulent ones, repel the phagocytes and so are left free to multiply, and harm their host. It was soon shown, however, that blood outside the body, blood in which the phagocytes had been killed by freezing, still had the power to destroy bacteria.

Some observers even went so far as to say, that Metschnikoff was wholly wrong; instead of the phagocytes swallowing and destroying the germs, these had invaded the phagocytes and were destroying them.

Metschnikoff, however, has brought forward evidence by means of stains, enabling him to show the difference between a living and a dead germ, to show that in some instances at least, the phagocytes do take in and destroy the bacteria. In certain other cases, however, as in gonorrhea, and mouse septicemia we must conclude from the enormous number of the germs present in a single phagocyte, and from their staining, that they have invaded the phagocyte, and multiplied at its expense.

Some three years ago, Dr. Vaughan and myself began some experiments on this question with the following results. In a paper before the Pan-Ameri-

can Congress, at Washington, we stated our views as follows:

From a careful and critical study of the investigations that have been briefly reviewed, we have come to the following conclusions:

"1. The serum albumin is not the germicidal substance in blood serum. As has been stated, either this must be true, or the experiment by which Buchner demonstrated that an active pepsin does not destroy the germicidal action of blood serum must have been an error; because peptic digestion readily and completely converts serum albumin into peptones, and we know that peptones are especially favorable to bacterial growth.

"2. The germicidal substance must belong to the proteids. Otherwise it would be difficult to explain the fact that a temperature of 55 degrees C. renders blood serum inactive.

"3. The only proteid likely to be present in blood serum and which is not destroyed by peptic digestion is nuclein.

"Having reached these conclusions, the following questions naturally present themselves:

"1. Is there a nuclein in blood serum?

"2. Has this nuclein, if there be one, germicidal properties?

"These questions we have attempted to answer.

"Dogs and rabbits were the animals from which the serum was obtained. Healthy animals that had not previously undergone any experimentation were selected. In each case the animal was bled to death. The flask containing the blood was placed in the ice-chest and allowed to remain for twenty-four hours. By the expiration of this time, a wine-colored serum had separated. This serum was poured into a second sterilized flask and about ten volumes of a mixture of equal parts of absolute alcohol and ether were added. This produced a voluminous precipitate that was nearly white. This was allowed to stand twenty-four hours, and in some cases much longer, the alcohol and ether twice, or more often during the time, being decanted and replaced by equal volumes. Then the supernatant fluid was decanted and an equal volume of 0.2 per cent. solution of hydrochloric acid containing active pepsin was added, and the flask placed in an incubator at 38 degrees C., and the digestion was continued until the fluid failed to respond to the biuret test for peptones. Each time this test was made, the fluid was decanted from the undigested portion and replaced by an equal volume of fresh digestive fluid. In some instances the flask containing this fluid was allowed to stand in the incubator for several days. This was not necessary in order to complete the digestion, but was allowed as a matter of convenience. In all cases the digestion was prompt and proceeded to a certain point, when it ceased altogether. The undigested portion was small in amount and grayish in color. This was collected on a small sterilized filter and washed first with 0.2 per cent. solution of hydrochloric acid, and then with alcohol. After the washing with alcohol, the filter was allowed to stand exposed to air for half an hour or longer, in order that all of the alcohol might pass through or evaporate. The precipitate was then dissolved in a sterilized solution of potassic hydrate. The strength of this alkalin solution usually employed was 0.12 per cent. Usually this solution contained in addition to the alkali 0.6 per cent. of sodium chlorid. In some instances a solution containing

1.2 grams of potassic hydrate, 6 grams of sodium chlorid, and 1 gram each of sodium bicarbonate and disodium hydrogen phosphate to one liter of water was employed as a solvent. The solution was filtered through a Chamberland tube and received in a sterilized flask. The solution thus obtained was perfectly clear, colorless, and did not respond to the biuret test.

"We have now answered the first question. Blood serum contains a nuclein. We hope to investigate at some time in the future the relation between this nuclein and fibrin-ferment.

"The origin of the nuclein found now for the first time in blood serum is an interesting question. Does it come from the disintegration of the polynuclear cells, or shall we regard white blood corpuscles as unicellular organs whose function it is to secrete this nuclein?

"In proceeding to determine whether or not this nuclein has germicidal properties, the solution was distributed in sterilized test-tubes, 5 c.c. being placed in each tube. It should be stated that in dissolving the nuclein, the volume of the solvent employed was in all cases the same as that of the blood serum from which the nuclein was obtained. These tubes were inoculated with different germs and plates made at varying intervals of time, in order to test the germicidal action. One and the same platinum loop was used in the preparation of each plate."

A number of experiments were then given in detail, showing that this nuclein had very decided germicidal power.

"We have made many other tests of the germicidal action of the nuclein obtained from blood serum, but as all of them gave practically the same results, further repetition is unnecessary.

"The fact that the germicidal constituent of blood serum can be isolated has an important practical bearing. Blood serum therapy has pronounced disadvantages, on account of the large amount of the fluid which must be injected. Nuclein therapy now promises to enable us to avoid this difficulty, and possibly the near future may find us using this agent in the treatment of disease. The nuclein may be obtained from an animal rendered immune to diphtheria, and a sufficient quantity of this injected into the blood or under the skin of a child suffering with this disease may effect a cure, but we will not prophesy. The future will tell us what it has in store when the future shall have become the present."

Since this was written, some two years ago, nuclein has been used extensively in the treatment of tuberculosis, and as we think with remarkable success. This work on the germicidal power of the nucleins has been confirmed by Kossel and others.

It seems to me that we have found an explanation that covers all the facts claimed by those who hold the phagocytic theory, as well as those who hold that the fluids of the body are its defenders.

Some one has suggested that the white blood cell is an unicellular gland whose business it is to secrete a germicide. As is claimed by Metschnikoff, there are obvious advantages to the animal in having the germicidal constituents of its blood (partly) in the form of amœboid bodies. Concentration at a desired place can be more easily accomplished, and the walls of the arteries and other tissues may be traversed without injury. But these cells do not eat and digest the invading bacteria. There are reasons for believ-

ing that they have no power to retard the progress of the invading bacteria until the constituents of the cells pass into solution.

Metschnikoff now regards nuclein as the germicidal substance in the blood. Suppose that it is shown that those indefinite substances which Hankin calls Defensive Proteids, Buchner Alexines, and Poehl Spermine, are nucleins, and that this substance is the one germ killing portion of the body, what have we gained?

How are we to explain the fact that of two individuals, living under the same circumstances, possibly of the same parentage, exposed to the same infective disease, the one takes it, the other escapes; or, both taking the disease, in the one, there is recovery and immunity to subsequent attacks, while the other dies?

How explain that at one age an individual is susceptible and at another immune to the same disease? That one animal is immune and another species very prone to die from a given germ? And above all how can we help the body in its ceaseless fight against disease germs? Some of the questions are as yet unanswerable, but day by day we are getting more light on these problems.

I have, so far, spoken only of the germ destroying powers of the body. It may be necessary to point out that in avoiding or recovering from disease, the body has to deal not only with germs, but also with their products.

It seems probable that the harmful effects of germs are not, as a rule, due to their mere presence, but principally to the poisonous products which they elaborate. In the case of tetanus the germs are found only in the neighborhood of the wound, while their effects are manifested, it may be, in every nerve and muscle in the body. So in diphtheria, the germs are practically confined to the upper air passages, and yet we find the deleterious effects of the disease in every organ of the body. These effects may be produced experimentally by injecting the filtered culture of the germ, without there being a single germ in the body. The paralyzes of diphtheria, or the tetanic conclusions of tetanus, can be produced at will in the laboratory with germ-free cultures.

These poisonous germ products, whether produced in our test tubes or in the body are called toxins. It is evident that if a child suffering from a severe case of diphtheria is to recover from the disease, it must be able, not only to destroy the germs themselves, but also to dispose of or destroy the toxins produced. The substances capable of destroying these soluble poisons are known as antitoxins. What are these antitoxins?

It may be well to point out, that the phenomena with which we are here concerned can not be explained, as was once supposed, by any theory of toleration. We know that there are many poisons, such as nicotin, arsenic and morphin, which when given in gradually increasing doses induce a tolerance on the part of the tissues so that eventually, many times the normal lethal dose may be taken without any serious manifestations. It can be shown that this effect is not due to any increase in the power of the body to destroy these drugs; in fact this power decreases. Not so, however, with the bacterial toxins; these are actually destroyed or rendered inert.

We take six guinea pigs, and give to each of them 1 c.c. of this diphtheria toxin. This toxin has been tried on some twenty or thirty guinea pigs and is

uniformly fatal in one-half c.c. doses. In a short time after injecting the toxin—on the opposite side of the body we inject into one of these pigs one-tenth of a c.c. (one drop) of this antitoxin, in another two-tenths, in a third five-tenths. The remaining three we leave with the toxin alone. I am describing experiments just as they were made in our laboratory some three weeks ago, and with these substances which I have here.

In forty-eight hours we find that the three pigs which received the poison alone, are all dead; the three receiving both toxin and antitoxin are alive and well. We take six more pigs. Into two of these we inject to-day one drop each of the antitoxin, twenty-four hours later we inject 1 c.c. of the toxin. These pigs never show at any time any symptoms of disease.

In a test tube we place 2 c.c. of the toxin and 2 drops of the antitoxin; after standing one hour one-half of this mixture is given to each of two pigs, these also show no sign of disease. The remaining pigs are given 1 c.c. each of the toxin and as in the preceding experiment are dead within forty-eight hours.

These experiments may be continued until many times the fatal dose of toxin is given, but if an appropriate quantity of the antitoxin is administered, no harm comes to the animal. Here there is a poison destroying power. What do we know of it? and how can the substance be produced?

We find here, just as when we study the bacteria themselves, that for a given germ or its toxin, certain animals are quite susceptible; others withstanding large doses of germ or toxin or, as we say, are immune. This immunity may in certain cases be borrowed from one animal and given to another. Thus one drop of the blood of a dog or frog, animals naturally immune to anthrax, if injected into the white mouse will effectually protect it against an inoculation of the anthrax germ. It makes no difference whether the drop of blood is injected several days before, or some hours after the inoculation with the germs. This, one experiment, and there are many similar ones, would at once suggest to us that the problems of cure and of immunity are closely connected, if not identical.

Now immunity may be natural or acquired. "Natural immunity may be peculiar to the species or race, or to the individual. An example of natural immunity is that of the domestic fowl to anthrax. As has been shown by Lazarus and Weyl, the chick, even at the time of coming from the shell, is immune to the most virulent culture of the bacillus anthracis. It is true that this animal may be made susceptible to anthrax, but this is an artificially-induced susceptibility. The immunity is natural to this bird at every period of its life. Another example of racial immunity is that of the frog to anthrax. This animal can also be rendered susceptible, but again it is true that the susceptibility is artificial and the immunity is natural. Racial immunity must be inherent in the parent cell.

"The natural immunity, which is peculiar to the individual, usually comes with adult life. The young are susceptible to a given disease, but adults of the same species lose this susceptibility and become immune. The young rat is susceptible to anthrax, while the adult is naturally immune, but can be rendered susceptible by exhaustive exercise. The child is highly

susceptible to scarlet fever and diphtheria; while the adult, though not wholly immune to these diseases, loses very much in susceptibility and is likely to become infected only when greatly reduced in vitality or after prolonged and aggravated exposure to the poison." In addition to the natural immunity due to race or age we have artificial or acquired immunity, as in the case of the mouse previously mentioned.

In 1880 Pasteur first showed that susceptible animals might be made more or less insusceptible to a contagious disease, and from that time to the present this artificial, or acquired immunity, has been the most interesting and important of bacteriologic problems.

Do natural and artificial immunity differ in degree only or in kind? This is an important question and one as yet undecided. The majority of investigators, following the lead of Behring, say that they differ in kind, that the germicidal and antitoxic powers are two different things. This is possibly true, and yet there are facts going to show that these are questions of degree only. In the last three weeks we have shown in our laboratory that nuclein from the yeast cell, has antitoxic as well as germicidal powers. A series of sixteen guinea pigs were treated for several days with yeast nuclein in varying amounts; they were then inoculated with twice the fatal dose of diphtheria toxin. Those pigs which had received doses of less than 2 c.c. of the nuclein, together with the control animals died; these receiving larger doses were not affected by the poison. The experiments were repeated with the same results. In a similar manner, rabbits have been made immune to tuberculosis and to pneumonia. The immunity to pneumonia is noteworthy, as these animals are very susceptible to the germs of this disease.

Aronson has shown that the blood of the untreated white rat has considerable antitoxic power against the diphtheria toxin, Behring and Wernicke to the contrary notwithstanding. Guinea pigs that had been treated with such blood showing marked increase in their resistance to diphtheria poison.

You will have noticed that all the work I have quoted has been the outcome of theory, and nowhere is the value of the scientific imagination shown better than in the results of bacteriology. "Again and again it has been shown that the value of a theory does not wholly depend upon its truth, but is rather to be measured by the fruitfulness of the lines of investigation that it opens. Indeed, a theory may be wholly erroneous and yet it may lead to most important discoveries."

Our theories of immunity, of the relation of acquired to natural immunity will have important bearings on the future of this work. At present, however, the attention of bacteriologists is attracted to the brilliant results that have been obtained in artificial immunity. It has been demonstrated, for example, that a horse, an animal very susceptible to tetanus, can be made so immune to the disease that it will withstand several million times as much of the tetanus toxin as would kill another and untreated horse.

The results in the treatment of diphtheria have been such as to elicit worldwide interest. Among the first workers in this line was Ehrlich. At that time it was impossible to obtain the bacterial poisons, toxins, with any degree of uniformity in their poisoning power. So that Ehrlich selected two poi-

sonous proteids or toxalbumins that had been obtained from the higher plants, as he could get these in relatively large quantities and with uniform toxic powers. These substances were ricin, obtained from the castor oil plant, and abrin from the jequerity bean.

This substance, ricin, is the most powerful poison we know. The contents of this bottle, 1 gram, 15 grains, Ehrlich estimates is sufficient to kill 1,500,000 guinea pigs. By giving his animals very minute and gradually increasing doses of these poisons; now in food, again hypodermically, and again by rubbing a weak solution on the conjunctiva of the eye, he was able at last to get them so immune that they would withstand several hundred times the fatal dose for an untreated animal.

He showed the best and quickest way to secure this immunity, and also the very important fact that his animals rendered immune to one of the poisons, say ricin, showed no immunity to the other one but were killed by it in the same dose that was fatal to the untreated pigs. Ehrlich went further, and showed that his animals did not merely tolerate the poisons, but destroyed them. He was indebted to Behring and Kitasato for this idea, they having in the meantime made the fundamental discovery that the immunity in diphtheria and tetanus was based upon a certain ability of the blood to neutralize the bacterial poisons. With this in mind, Ehrlich at last found that such a substance existed in his immune animals. These substances he called anti-ricin and anti-abrin. This discovery was the basis for all that we know of antitoxins.

Behring and Ehrlich next established the fact that the blood taken from immune animals rendered other animals immune. Discoveries now followed each other in rapid succession. Ehrlich demonstrated that the offspring of an immune mother was for a time immune. Further, that the immunizing or antitoxic substance was present in the milk of the immune mother, and could be transmitted in the milk of an immune nurse, even when the nursing was no relation to the nurse, and the offspring of very susceptible parents. This gives us an explanation for the well-known, but heretofore little understood fact, that the suckling is more or less immune to several diseases to which it is very susceptible after weaning, as scarlet fever, measles, etc.

Further experiments led to a method for quantitatively estimating the value of the antitoxins, and the duration and degree of the immunity. The results of these discoveries are far reaching. By appropriate treatment we can give an animal such a high degree of immunity to a certain disease, that a relatively small quantity of its blood or blood serum, will contain sufficient poison destroying power, or antitoxin, to neutralize all the poison produced in an ordinary case of this disease. The blood serum of this immune animal we can borrow without detriment to the owner; we can bottle it, preserve it, if need be send it thousands of miles and there give its hoarded strength to one in need.

The method of immunizing animals against tetanus and diphtheria has been published so widely that I pass it by. As to the results of the antitoxic treatment in these diseases I may say, in brief, that the mortality in tetanus has been reduced from 80 to 20 per cent. In diphtheria, an average of many estimates shows a death rate diminished one-half under

this treatment. Behring believes that the mortality will not exceed 5 per cent. if the treatment is begun within forty-eight hours after the attack. Roux holds that the treatment is not very effective in those cases complicated by a streptococcus infection. But these figures, good as they are, a saving of one-half of the children who die of this dread disease, do not nearly represent the value of antitoxin. Its greatest promise is in the way of immunity, prophylaxis. We will have little need of a cure for diphtheria if every child exposed to the disease can have an injection of antitoxin and thus escape an attack. This result is promised by this new remedy.

Now to return to a question previously raised, How do the antitoxins neutralize or destroy the toxins?

We have seen that when a lethal dose of toxin is injected it fails to have any harmful effect, if, at the time a sufficient quantity of antitoxin is injected. The results are the same whether we mix the antitoxic serum with the toxin and inject both together, or we inject them separately in different parts of the body, or finally, whether we inject the antitoxic serum twenty-four hours before injection of the poison. It is quite different, however, if we inject the antitoxin some time after the injection of the poison. The longer we delay the more unfavorable is the prospect of cure, the greater is the quantity of antitoxin required, and the more uncertain becomes the result.

Behring and his followers hold that toxin and antitoxin chemically neutralize each other and are both changed or destroyed in the process, just as when an acid and a base form a neutral salt—unite and neutralize each other. But there are, possibly, other explanations of this phenomena.

Many experiments go to show that when we mix toxin and antitoxin in test tube and then inject the mixture into an animal the toxin is destroyed but some antitoxin remains, capable of protecting the animal against small doses of the poison subsequently injected.

On the other hand, if the toxin alone is destroyed, we should expect that in our test tube mixtures, after a certain length of time, all the toxin would be destroyed and the antitoxin remaining would be capable of destroying a fresh quantity of the toxin—just as pepsin is capable of converting an indefinite amount of proteid into peptone. But experiments fail to justify any such conclusion.

These and similar experiments lead us to doubt the direct poison destroying of toxin by antitoxin. If that were true it should make no difference, except in quantity, at what stage of the disease we injected our antitoxin. We have seen, however, that it does make a great difference, often requiring in diphtheria five hundred times the dose to save an animal twenty-four hours after infection as before. The dose needed to cure in tetanus is a thousand million times the immunizing dose. Buchner carried out the following ingenious experiment: Ten white mice and ten guinea pigs were given injections containing 1-10 mg. of a tetanus toxin. As was to be expected, all the mice died with pronounced symptoms of tetanus poisoning. The guinea pigs lived, only a few of them showing transient symptoms of the disease. In the second experiment, twenty-three mice and twenty-three guinea pigs were used. Each of them received 14 mg. of tetanus poison, one hundred and forty times the amount which in the first series was sufficient to kill the mice. But with the tetanus toxin, 1.35 mg.

of an antitoxin had been mixed. Through this quantity of antitoxin the activity of the tetanus poison was almost destroyed. Nine of the mice were unaffected, eleven showed slight symptoms of the disease, while only three died.

As in the previous series 1-10 mg. had proved uniformly fatal to the mice, we must conclude that in this experiment the larger part of the toxin, certainly 13.9 mg. had been destroyed, otherwise the remaining 1-10 would have certainly killed the animals. Now exactly the same dose of toxin and antitoxin is given the twenty-three guinea pigs.

The previous experiment has shown that 1-10 mg. of the poison has but little effect on the guinea pig; this experiment seems to show that the antitoxin present is sufficient to destroy all but 1-10 of the poison in the mixture; hence we should expect to find little if any effect on the guinea pigs. On the contrary, eight died of marked tetanus, twelve showed chronic tetanic symptoms, and only three remained unaffected; showing conclusively that the antitoxin could accomplish results in the body of the mice which it could not in the guinea pig.

A study of this and other experiments, it seems to me, must force us to the conclusion that there is no destructive action of toxin by antitoxin, either in the test tube or in the body; but both substances act only through the intermediation of the cells of the body or, in other words, the action of the antitoxin is only an immunizing not a destructive one. There is in the strict sense of the word, no "antitoxin," but instead an immunizing substance.

Again the question, What is immunity? Before attempting any speculations on this question, it is necessary to call your attention to some facts regarding the nature of toxins. These, all are agreed, are albuminous bodies, toxalbumins as they are called—related to the poison of stinging insects, the venom of serpents.

Roux and Yersin in Pasteur's laboratory were the first to demonstrate the nature of these substances. They regarded the poison as a sort of enzyme or soluble ferment. This view has been adopted by Brieger and Fraenkel. This was the only way in which they could account for the intensity of the poison. By a ferment action, splitting up the albumins in our culture fluids, or in the body, they could account for the poisonous effects of the bodies. But in the laboratory of Straus, in Paris, it was shown that there was no diminution in the diphtheria poison when the germs were grown in albumin free urine. Buchner, in Munich, grew his tetanus germ in a solution of asparagin and mineral salts. Here, there could be but one source of the proteid poison, the cell contents of the bacteria themselves. Buchner concludes that the tetanus toxalbumins spring directly from the plasma of the tetanus cell.

Most writers on this subject assume that bacterial poisons are secretions or excretions of the germs producing them. But the ordinary method in use for obtaining the toxin of diphtheria disproves this. In our flasks of bouillon inoculated with the germ of diphtheria and kept at body temperature, there is every reason to believe that all growth and reproduction of the bacteria come to an end after two or three days, and yet before this fluid has attained its greatest toxicity it must be kept for some three months. Now what happens in that time? If we examine portions of the culture from time to time with

the microscope, we notice that the germs gradually lose their staining reaction and are slowly macerated and finally dissolved in the bouillon. The filtered fluid which at the end of three days had very little toxicity is now intensely poisonous. Here again we are led to believe that the source of the poison is in the bacterial cell. But I can not agree with Buchner that it comes from the cell plasma. In the last three weeks I have attempted to extract the poison from fresh cultures of the germs. By using the ordinary methods for extracting nuclein I have obtained an exceedingly poisonous substance, giving when injected, apparently the same symptoms as the toxin obtained from old cultures. If the bacterial poisons are nucleins it will help us to explain the phenomena of immunity and cure. That they are nucleins seems to me altogether probable even on theoretical grounds. The poison of the tetanus cell differs markedly from that of the diphtherial; the one produces tetanic convulsions; the other complete paralyses. Now we have many reasons to suppose that the protoplasm of all cells is much alike—that which gives the cell its morphologic or physiologic individuality comes from the nucleus.

I am aware that there are facts opposed to this view and I only offer it as an hypothesis. Brieger and Fraenkel have shown by analysis that tetanus toxin contains neither phosphorous nor sulphur. Malm has shown that a purified tuberculin contains no sulphur. How can they be proteids, much less nucleins? But the albuminous substance of the bacterial cell, according to Neucki, "is not precipitated by alcohol, and differs in its chemic composition from other known substances of this class." He calls it *mykoprotein*, and says that it contains no sulphur and no phosphorus. If these observers are right we must enlarge or modify our views as to the nature of proteids.

With all the preceding facts before us, what insight do we get in the problems of immunity and cure?

Pasteur's "exhaustion" theory asks us to believe that in case of natural immunity there was lacking in the organism a something necessary to the life of the microbe; that in acquired immunity, the attack of the disease—the growth of the germs within the body had exhausted this necessary food and until it was replaced the animal was immune. This theory is no longer sustained by Pasteur, or his pupils, and is evidently untenable.

The "retention" theory as proposed by Chauveau, is subject to similar objections. To suppose that an individual who has had scarlet fever, diphtheria, measles, smallpox, etc., retains in his body certain products which are capable for years, or even a lifetime, of protecting the body against these diseases is to ask a great deal of our credulity. Note that the theory requires a separate substance for each of the diseases. The child who has had, and is now immune to diphtheria is still susceptible to measles, etc. Moreover, we must under the theory suppose that the diphtheria poison for example, which now affects the organism so powerfully, is after recovery retained in the body without any deleterious influence. That the body could retain so many different poisons, for such lengths of time, and that these poisons could be tolerated with no ill effects seems to me to be bad physiology and poor theory.

Sternberg has elaborated a theory of immunity based on the idea of tolerance to poisons. Without

giving the arguments advanced for and against this theory, I may say that, as it seems to me, there is abundant experimental evidence to show that these poisons are not merely tolerated; they are destroyed or at least disposed of.

Metschnikoff on his "phagocytic" theory would explain immunity in this way: Immunity and cure are essentially the same thing, or as he expresses it "most often immunity is but recovery in operation from the very onset of a disease." Disease germs which are not very malignant to the body exert a positive chemiotaxis or attractive power for the phagocytes; these in turn swallow the germs and destroy them. This ability to destroy the germs, and to be attracted by them, increases with use and is hereditary. Hence in the case cited, sooner or later the germs are overcome and on account of the educational process which the phagocytes have gone through, they retain for a longer or shorter time this power, or there is immunity.

Artificial or induced immunity, he explains, by supposing and in some cases demonstrating, that when there is negative chemiotaxis for the malignant germ, for the attenuated germ there may be a feeble positive attraction; this is increased by use until gradually the most virulent germs of this kind attract the phagocytes only to be destroyed. So when the tissues are gradually subjected to bacterial poisons, in this method of immunizing, the phagocytes are gradually educated.

I feel that I should apologize for such a brief and unsatisfactory presentation of the really beautiful and weighty theory of Metschnikoff.

I wish to call your attention to one more theory in regard to immunity. This is a theory advanced by my teacher, Vaughan, of Michigan. For the most part I shall use his own words:

"There are three methods of inducing immunity which reduce themselves to one and the same principle, *i. e.*, the introduction of germ nuclein into the body. This nuclein may be either inclosed in the cell wall or in solution. These methods are: 1, by the use of very small numbers of the virulent germs; 2, with living bacteria modified and reduced in virulence, attenuated culture; 3, dead bacteria morphologically intact or in solution. In all cases the cause that brings into existence the condition of immunity is a bacterial proteid. I call these proteids, and I wish it to be understood that I do so tentatively, and that I recognize the fact that the exact chemic nature of none of them is known; but for the present we may call them proteids. For reasons already given, I believe that the proteids which induce immunity belong to the class of nucleins."

How can we explain immunity with these facts before us? Briefly thus: the nucleins of the animal body have the power, or under certain conditions may be so trained or educated that they assimilate the bacterial nuclein. We have seen that toxin must be regarded as a specific product of the bacterial cell. Toxin and antitoxin from their very nature should be closely related, possibly only different modifications of the same substance. The fact that one is poisonous and the other not, that the one heals while the other kills, does not contradict this assumption. We have many examples of closely related substances which differ widely in their physiologic effects. From the comparatively harmless cholin the very poisonous neurin is produced by the simple abstraction of water.

"These different nucleins, that of the bacterial cell, and that of the blood, may be isomeric bodies, one of which may be designated as the  $\alpha$ -compound, and the other as the  $\beta$ -compound, and one of these by simply causing a rearrangement in the atoms within the molecules of the other may assimilate the second. We do not mean to say that the process by which a nuclein assimilates another proteid is as simple as would be indicated by these examples, but they may suggest something of the nature of the chemistry of assimilation. We may assume that when an alpha-nuclein and a beta-nuclein are brought together, one will assimilate the other; and which one will absorb the other, will depend upon the relative strength or vitality possessed by them, and in measuring this strength several things must be taken into consideration. A vaccine has less of this power of assimilation than a germ of full virulence, and a nuclein in a sterilized culture less than either of the others.

"An organ that has once been stimulated by a given excitant responds more quickly the second time to the same excitant, provided that the interval of time is not too great. This explains the gradual loss of acquired immunity.

"Again, an organ that is stimulated by one excitant may not be responsive to another, and this accounts for the fact that an animal rendered immune to one disease remains susceptible to another.

"We can suppose that the process of immunizing an animal proceeds in something like the following manner: The modified virus of tetanus is introduced into some distant part, in some unknown way; the spleen is stimulated to action, and secretes a nuclein which is carried partly in solution, partly in the form of multinuclear cells to the invaded part of the body, and the tetanus poison is converted into the nuclein coming in contact with it, or is otherwise rendered inert. Later, a larger quantity of the tetanus poison is introduced, and now the spleen acts more promptly and energetically than before. This promptness and energy of action are increased by exercise and, finally, an amount of tetanus culture, of full virulence, sufficient to kill an animal whose spleen has not been subjected to this training may be introduced without ill effect. On this theory, the production of immunity consists in a special education of certain cells."

Now what have we learned from this review of these theories and experiments? We have seen that the body has the power to kill bacteria; that this power resides chiefly if not wholly in its soluble nucleins. On this fact is based nuclein therapy. We endeavor to aid the body when it is engaged in a losing fight, by giving it a nuclein closely related to its own, which it can readily assimilate and in turn use as a defensive agent.

We have seen that the body has a poison destroying or antitoxic power; that we can increase this to an enormous extent in certain animals, and that we can borrow this power from one animal and lend it to another. On these facts serum therapy is based.

We have seen that there are some reasons for believing that these germicidal and antitoxic powers are related; that in a strict sense there is no antitoxin but only an immunizing substance; that the problems of cure and immunity are probably identical. And I trust that we have seen that nucleins and antitoxins are not chance discoveries, but are the results of the investigations of many workers. A theory here,

an experiment there—step by step—until at last the bacteriologist offers to humanity the results of his labors.

In conclusion: Men have for ages sought to find specific remedies for diseases. There are but few substances,—mineral, vegetable, animal or the products of the chemist, but have been tried. These attempts have been well summarized by Rossbach as follows: "For thousands of years mankind has experimented in this direction and the result has been the discovery of but four remedies for three diseases. It would be a terrible idea, that some other thousand years were necessary to detect another four remedies. The usual way of proceeding is too dangerous. Especially harmful proves the enthusiasm, not to say dishonesty of many observers. If by chance, a physician has found a remedy, after the application of which one or two cases of an infectious disease have quickly recovered, the success is at once attributed to the medicine. No thorough investigation on a larger scale is made, the new 'specific' has been discovered and is emphatically recommended."

We are learning better methods. Before attempting to find remedies we study the etiology of a disease. Having found the cause,—its noxious principles,—the way in which it harms, we then endeavor to discover the agents with which the body combats the "disease powers." Then, and not until then, are we in a position to intelligently seek for remedies. With this method, medicine seems to be entering on a new day.

The brilliant results that are being obtained in tetanus and diphtheria lead us to hope that many, it may be most of the contagious diseases may be subdued. With the same methods, experiments more or less successful have been made with septicemia, erysipelas, typhoid fever, tuberculosis, etc. But when we remember that two-thirds of mankind die of germ caused diseases we hesitate and fear to prophecy.

## THE MEDICAL COLLEGE FRATERNITY, NU SIGMA NU.

BY BAYARD HOLMES, M.D. (ETA CHAPTER).  
CHICAGO.

Perhaps this effort to bring a college fraternity to the notice of the medical profession will not be approved by many public-spirited physicians. The wars between the Greeks and the barbarians are still going on in all our American colleges and universities. Much can be said for and against the fraternities as they exist or have existed. Medical men are no exception to the mass of educated men in being prejudiced either for or against the Greeks. This article is written to inform, not to convert.

The introduction of fraternities into medical schools marks a distinct stage in the development of medical education. While the medical college was open only a few weeks each winter for bombastic lectures embellished with obscene stories on the part of teachers and for boisterous cramming on the part of students, all repeated once or twice on successive seasons, there was neither time nor incentive for fraternity life. The medical students of those halcyon days rarely knew many of their classmates in after life. As times and customs changed and the medical term was extended to eight or nine months for each of three or four successive years, the medical college became the home of a social unit. It was natural

that the precedent of the literary colleges in America should be followed by the students in these new medical centers and that Greek letter societies confined to medical schools should accordingly be established.

There are traditions of little fraternities in nearly all of the older colleges. None of these, however, attempted to become national in character until the establishment in a formal way of the Nu Sigma Nu at Ann Arbor. From a humble beginning at the University of Michigan in 1882, this order now numbers nine chapters and a membership of about one thousand. The membership in each chapter is limited to eighteen active student members. The existing chapters are:

- A. Alpha, University of Michigan (1882).
- B. Beta, Detroit College of Medicine (1889).
- Δ. Delta, Western Pennsylvania Medical College (1891).
- E. Epsilon, University of Minnesota (1891).
- Z. Zeta, Northwestern University (1891).
- H. Eta, College of Physicians and Surgeons, Chicago (1892).
- Θ. Theta, University of Cincinnati (1892).
- I. Iota, College of Physicians and Surgeons, New York (1893).
- K. Kappa, Rush Medical College (1893).

Gamma Chapter has surrendered its charter.

The order stands for high scholarship and professional integrity. Its teachings are of the highest ethical character and the discipline of the order has been mild but effective. There has so far been no manifestation of snobbery, which is the rock upon which many fraternities break. Perhaps the spirit of the fraternity can be best exhibited by relating some experiences in the Eta Chapter. This chapter was organized three years ago. Over half the men were graduates of literary colleges and the active members have always been and are men of superior education and ability. Nearly all are total abstainers. At the banquets of this chapter no intoxicants have ever been used. A majority of the present active members live together in a flat which is called the Chapter House. It has been a great pleasure to me to drop in and see a little of the life there. The rooms are very pleasant and are furnished like a modern home. Music and pictures give the convivial spirit of community expression. An occasional visitor keeps alive the genial spirit of hospitality. For a few days, one of the fraters was sick and I found him well cared for by the other residents. The table is furnished by the occupants of the adjoining flat. It is not what one would call lavish, but it does very well and is dignified and satisfactory. The Chapter House is not only the home of the students but it is also the home of the chapter and the place of all regular meetings and entertainments. The influence of this chapter in promoting fraternity life seems to be very great. An older man looks with great satisfaction at the growing friendships which he sees in the relatively young under his instruction and care.

In this chapter the most favorable reaction of the stronger and rougher upon the weaker and more refined has been observed; of the true and exacting upon the politic; of the genial and effusive upon the reserved and diffident. It is not difficult to predict for the men who thus live together,—all for one and one for all, in this little social community,—great

pleasure in after life from these well cemented friendships. Each one has been a gainer. Each one has become a truer man, a better student, and will be a broader physician from the culture of this fraternity life. A few of the residents are working for honors and hospital positions. No records have yet been made.

In the college, the sentiment was for a time strongly against the fraternity and fraternity men. By a very carefully executed policy of non-interference and non-resistance and by a concerted effort at conciliation, nearly all the opposition has now subsided. A chapter of the medical order of *H. P. Σ.*, has lately been introduced with a full membership among the very best men in the institution, and this, it is hoped, will allay the remaining prejudice against the older fraternity.

The last grand council of the order was held with Zeta Chapter during the World's Fair. Prof. Nicholas Senn gave the council a complimentary clinic at Rush Medical College and a banquet was held at the German Press Club. John L. Irwin, M.D., was elected Grand President, and W. J. Lyster, Harper Hospital, Detroit, Acting Secretary. A directory of the fraternity has lately been published. The names of many members of the faculties of the colleges in which chapters are located are to be found in this directory as honorary members. Some of the most distinguished physicians and surgeons in the country are thus enrolled. With careful discipline and a discrete propaganda, the Nu Sigma Nu will be a powerful factor in medical life and education during the next twenty years.

## PERITONEAL SUPPORTS—(LIGAMENTUM PERITONEI.)

BY BYRON ROBINSON, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE SCHOOL,  
CHICAGO.

The peritoneal supports of the abdominal viscera have received different names and appellations. In the Latin language they all come under the term, *ligamentum*, but in the general English in vogue the supports are called: *a*, ligaments; *b*, mesenteries; and *c*, omenta. The term, *ligament*, is applied to a fold of peritoneum which supports the more solid portions of the digestive organs as the liver, pancreas and spleen, yet is not restricted to these organs but is applied to the peritoneal supports of the genitourinary organs. The term, *omentum*, is generally applied to a fold of peritoneum which stretches from the stomach to some other organs. There are three omenta stretching from the stomach to the liver, colon and spleen. The term, *mesentery*, is applied strictly to the small intestinal support, but general usage extended it to the supports of the four parts of the large bowel. The synonyms for the term, *mesentery*, are, *mesaraion*, *mesaræum*, *medianum*, *membrana pinquis intestinorum*, *Lactes*, *Mesenteron*, *meseræum*, *mesoræum*, *medium intestineum* and *epichordis*. Latin, *mesenterium*; French, *mesentere* and German, *Gekröse*. Some writers apply the word, *mesentery*, to the whole of the peritoneal supports. The utility of the peritoneal supports are:

1. To retain an organ in a definite position.
2. To hold the viscera in definite relations so that entanglement is prevented. To prevent volvulus strangulation, dislocation or misplaced pressure.

3. To limit the viscera in physiologic and anatomic relations.

4. To allow sufficient independent motion for the viscera to functionate. From the peritoneal supports allowing such freedom by slender neuro-vascular styles on the various viscera, arises the difficulty of acquiring accurate anatomic knowledge of visceral anatomy. The difficulty of acquiring correct views of visceral relations consist of three peculiarities of the viscera, viz., *a*, the abdominal organs allow a wide range of movement without becoming dislocated; *b*, the organs can alter their conditions without losing their integrity to return to normal; *c*, they are highly endowed with elasticity.

5. The supports serve to some extent to prevent hernia.

6. A special utility of supports is to transmit vessels and nerves to viscera.

7. The elongated visceral supports allow the organs to pass through their rhythm.

8. The supports allow the law of compensation, *e.g.*, when one viscus enlarges the elongated supports of others give them a chance to glide out of pressure, out of the way of harm.

9. The most common pathologic condition of peritoneal supports is elongation (frequent after 35 years of age).

10. Anomalies of peritoneal supports are not common. Their origin is nearly always due to peritonitis.

The following table of the chief peritoneal supports I have prepared for the purpose of noting the English and Latin appellations of the same, and also to show at a glance the variety and kind. The scope and number are more easily comprehended in a compact diagram:

FIG. 1—Represents the primitive mesentery and digestive tubes of mammals. S, stomach; M, mesentery; I, intestine; A, aorta. The straight digestive tube is suspended from its dorsum by a simple double bladed membrane.

Suspensory ligament of the liver. (Ligamentum suspensorium hepatis.)

Round ligament of the liver. (Ligamentum teres hepatis.)

Right lateral ligament of the liver. (Ligamentum triangulare hepatis dextra.)

Left lateral ligament of the liver. (Ligamentum triangulare hepatis sinistra.)

Coronary ligament of the liver. (Ligamentum coronarium hepatis.)

Gastro-splenic ligament. (Ligamentum gastro-lienale.)

Phreno-splenic ligament. (Ligamentum phrenico-lienale.)

Left costo-colic ligament. (Ligamentum phrenico-colicum sinistra.)

Right costo-colic ligament. (Ligamentum hepato-colicum.)

Hepatico-colic ligament. (Ligamentum hepato-colicum.)

Ascending mesocolon. (Mesocolon ascendens.)

Descending mesocolon. (Mesocolon descendens.)

Transverse mesocolon. (Mesocolon transversum.)

Lesser omentum. (Ligamentum gastro-hepaticum.)

Greater omentum. (Ligamentum gastro-colicum.)

Gastro-splenic omentum. (Ligamentum phrenico-esophageal.)

Phrenico-esophageal ligament. (Ligamentum phrenico-esophageal.)

Mesentery. (Mesenterium.)  
Broad ligament of the uterus. (Ligamentum latum uteri.)  
Round ligament of the uterus. (Ligamentum teres uteri.)  
Utero-sacral ligament. (Ligamentum sacro-uteri.)  
Utero-vesical ligament. (Ligamentum vesico-uteri.)  
Gastro-pancreatic ligament. (Ligamentum gastro-pancreaticum.)  
Infundibulo-pelvic ligament. (Ligamentum infundibulo-pelvicum.)  
Posterior ligament of the bladder. (Ligamentum recto-vesicale.)  
Lateral ligaments of the bladder. (Ligamentum vesico-laterale.)  
Suspensory ligaments of the bladder. (Ligamentum suspensorium vesicale.)

FIG. 2—Represents the final peritoneal structure in man. L, liver; L.O, lesser omentum; G.O, great omentum, drawn aside by two hooks; D, the outline of the duodenum; F.D.J, fossa duodeno-jejunalis; M, mesentery; S.M, meso-sigmoid; Y.A, appendix with its mesenterolum.

#### THE MESENTERY.

In various valuable works it will be observed that the word mesentery, is used to embrace all that is finally covered by the word, peritoneum. I wish at this place to discuss the origin of the mesenteries—the neuro-vascular pedicles of the viscera.

The works of Toldt and Gegenbaur may be mentioned as samples of such titles as the mesentery. The digestive tract is so intimately associated with the peritoneum that they are both studied together, as may be noted in Treves' little pamphlet, "Intestinal Tract and Peritoneum in Man." In the present work I shall consider the development of the digestive tract and peritoneum together, and that the development of the one can not be comprehended without the other. There can be no serous cavity without viscera. The viscera produce the cavity by their presence and advancing growth. The moving viscera and independent moving of adjacent walls are accountable for the serous lymphatic sac. In fact, the very relation of sac to organs also shows one depends on the other, for the peritoneum envelops the organs, without inclosing them, like a tightly fitting night-cap. A good illustration of the peritoneum is a frieze on a house, where the figures are represented in relief, but all the elevations and depressions are covered. The figures are thrust forward on the frieze, invaginating or carrying the surface with them. The idea of the inseparability of the abdominal viscera and the peritoneum can not be more forcibly impressed on the reader than to say that arrest of visceral development is nearly always due to peritonitis, *e.g.*, the non-descent of the cecum, which I have seen six times, was in each case due to old or recent peritonitis.

A mesentery in general consists of a double fold of peritoneum, which partially invests a viscus. No viscus is entirely covered by peritoneum. The point on the organ where the membrane diverges to envelop it, leaves a space uncovered by peritoneum. A mes-

entery is generally considered as such when its blades after diverging again come in contact before reaching the line of parietal insertion. As illustration of this idea the right or left colon may be taken. If the peritoneum covering the anterior and lateral surfaces of the colon does not come in contact between the posterior surface of the colon and dorsal wall we say there is no meso-colon. With no meso-colon the posterior surface of the bowel is in contact with the connective tissue of the dorsal abdominal wall. Should there be a mesentery of the colon, the layers of peritoneum which invest the lateral and anterior bowel surface approach to contiguity between the bowel and dorsal wall. In human anatomy the word, mesentery, is by general consent limited to the small and large bowel.

FIG. 4—Represents the mesentery with the chief part of the small intestine cut away (after Sappey).

As the digestive canal is developed, the peritoneum is also developed. The double layers of peritoneal membrane anchor the canal to the posterior abdominal wall and this anchorage is the mesentery. That part of the mesentery which passes to the stomach is called the mesogaster, anterior or posterior. At this point we have both a posterior and an anterior mesentery. Beginning at the middle line of the dorsal wall two layers of peritoneum (mesogastrium posticum) pass to the posterior border of the stomach. These two layers of peritoneum diverge, pass forward on each side of the stomach and again come in contact on the anterior border or lesser curvature, after which they (mesogastrium anticum) pass to the anterior abdominal wall. That portion of the double fold of peritoneum which extends from the liver to the abdominal wall and down to the umbilicus and is known as the suspensory ligament (ligamentum suspensorium) of the liver is a part of the anterior mesogaster. The mesogastrium anticum or lesser omentum has deviated from the middle line to the right, away from the remnant of umbilical vein, by the irregular and rapid growth of the liver. The remainder of the digestive canal has no anterior mesentery, having lost it by absorption or atrophy. In human anatomy the mesogastrium posticum and anticum bear the names of greater and lesser omen-

tum. They are then mesenteries with other acquired names. As long as the digestive canal maintains its original straight course the relations of its mesentery are simple. The peculiarities of its mesentery are all acquired, and in fact the only primitive mesentery left in the adult is the mesentery of the sigmoid. The liver grows rapidly and irregularly, displacing organs and appropriating large areas of peritoneum. The stomach rotates and twists, assuming new forms and positions. The great intestinal loop rotates and

FIG. 5—"A" represents an early mesogastrium anterior and posterior before torsion. 1, anterior abdominal wall; F, liver; E, stomach; 3, lesser omentum; D, duodenum; 1, remnant of vitelline duct (Meckel's diverticulum); 5, mesogaster posterior; 2, vertebral column; 4, 4, primitive mesentery; L, great intestinal loop; R, spleen, (after Deblierre).

changes the original mesenterial attachments. The kidneys rapidly enlarge and steal away the mesenteries of the colon ascendens et descendens. Still further changes of the mesentery arise from the fact that the small bowel grows more rapidly in length than its mesentery and hence the intestine is thrown into frill-like folds. These changes in the simple primitive mesentery are manifest in fishes; as the scale of animal life ascends, the most complicated acquired arrangements are found in man. In watching the development of the mesenteries from a simple straight fold, embracing a simple straight tube, through evolutionary stages to complications which are almost incapable of being unravelled, the mechanical idea of peritoneal development must be thrown aside. The whole matter must be considered under

FIG. 3 and 6—"B" and "C" represent progressive torsion and formation of mesenteric supports. 1, anterior mesogaster; 2, posterior mesogaster; E, stomach; C, colon; 1, vitelline duct; I, small intestine; V, cecum; 4, mesocolon; 5, mesorectum; R, rectum; 3, in "B" mesoduo-denum, and 3, in "A" mesentery, (after Deblierre).

readjustments of parts and relations. Some organs appropriate peritoneum by rapid growth, while others yield a portion from shrinking. Hypertrophy, atrophy and changes of position of viscera account for peculiarities of peritoneal arrangement in adults. Remnants of embryonic life, the peritoneal recesses formed by blood vessels contained in folds of the membrane account for changes in the mesenteries.

In a completely formed mesentery we have three distinctly formed layers to observe. The two superficial layers consist of an epithelial membrane of a whitish pink color, glistening, moist and smooth to the touch and covering the organs out of sight with an unbroken surface. The third, middle or essential part of the mesentery is the connective tissue lying between the superficial epithelial layers. This is the *membrana mesenterii propria*. It includes in its meshes veins, arteries, lymph vessels and nerves and occasionally some muscular fibers. This is the essential structure which serves as scaffolding to support in the definite relations vessels and nerves. It is a fibrous bed in which vessels and nerves securely lie. The fibrous tissue in the mesentery surrounding the vessels and nerves is dense, strong and often sufficient in quality to bury the vessels or nerves out of sight. This mesentery can be seen as early as the fourth embryonic week, in the human, with a strong lens. It then stretches from the mid-dorsal line to the straight digestive tube. At this time no sign of fat is visible with the strongest lens.

I have made careful examinations of the mesentery at six weeks of human embryonic life, when the digestive tube had just begun to distinctly show the bend for the great intestinal loop and the dragging of the duodenum to the right with its mesentery. At this age (six weeks) with a strong lens and the mesentery in a good light, it is plain to see white strands of connective tissue forming the *membrana mesenterii propria*. At certain points the mesentery is more transparent than at others. It is made non-transparent or opalescent by the accumulations of bundles of fibrous tissue. The bundles of tissue do not seem to have any distinct order, but seem to follow in general parallel with nerves and vessels. The change of this middle mesenteric connective tissue layer is not very manifest as fetal life advances. The bundles of nerves and vessels are securely united and fixed by the *membrana propria* in extensive qualities. As the nerves and vessels approach the gut they become more scattered and less parallel. The fibrous tissue also becomes more scattered and diffuse. The whole mesentery becomes thin among the arches of the mesenteric arteries. In the two months' human embryo, and in the horse, I have noticed it astonishingly thin. In most cases it may be noted that just as the mesentery divides to embrace the bowel, the middle mesenteric layer again increases in connective tissue. This serves the useful purpose of properly distributing the small vessels and nerves on the digestive tube. It also gives the bowel an opportunity to contract and expand in an elastic bed of tissue. About the fourth month of human embryonic life, the *membrana mesenterii propria* assumes more manifest proportions. The mesentery becomes thicker and stronger. It assumes more of the character of adult life. But the special change in the mesentery which occurs so manifestly at the fourth fetal month is the rapid increase of, not only the size of the blood vessels and nerves, but the sudden increase of the connective tissue fibers lying around them. The great trunks of blood vessels lie solidly and firmly embedded in the quickly increasing bundles of fibrous tissue, while the lateral small branches pass off in less compact surroundings. This connective tissue lying between the mesentery is governed very much by the blood vessels and probably nerves, for when the blood vessels become manifestly large at the

fourth fetal month the tissue accumulates step by step with them. This tissue is the guardian of the vessels and nerves to sustain and protect relations. In later fetal life the arrangement of fibrous bundles of sub-peritoneal tissue must be wrought in the line of blood vessels. A small amount of dissection will soon demonstrate that these fibrous bundles between the mesentery run parallel to blood vessels in general, and entwine and weave themselves around the channels which carry nourishment. Between the trunks of vessels one can observe the *membrana mesenterii propria* more as a membrane, dense and strong, which holds the parts in definite relations. In very spare infants of six months old or in very spare cadavers of adults, I have often dissected it and was surprised at the strength of the membrane. Yet it varies in different individuals. It is not so apparent in fat subjects, but in the sense of distinctly observing its wide meshes the fat subject is the best, for all fat is contained in the meshes of the *membrana mesenterii propria*. Perhaps this membrane can be seen the most typically in the horse, with his enormous-sized mesentery. It looks almost like fibers of white tendon in this animal. In a spare infant cadaver, of six months, the membrane is very thin, but in that case shows its fibrous character. It may be observed that by careful dissection on a spare adolescent cadaver it will be easy to note muscular fibers passing from the celiac axis and its adjacent region into the mesentery. In some subjects this muscle (*musculus suspensorius duodeni* or, better, *mesenterii*) is abundant, while in others it is difficult to find it at all, especially if the cadaver be old and long dead, or injected with decolorizing agents. Again, with the increase in size of the blood vessels, the fibrous bundles in the mesentery accumulate so rapidly along the blood channels that the deficiency of the fibers in the intervening spaces becomes more apparent. The view would hence arise that the *membrana mesenterii propria* has some directing influence over the vascular channels. Even the existence of the mesentery itself depends on the ordering of the blood channels. For, in certain areas in the mesentery, chiefly at the lower ilium, we may find in man and lower animals spaces almost devoid of blood vessels. These areas are so thin that a slight trauma would perforate the mesentery.

(To be continued.)

## NEPHRORRHAPHY FOR MOVABLE KIDNEY (LEFT).

Read before the Chicago Pathological Society, Jan. 14, 1895.

BY E. F. GAVIN, M.D.

CHICAGO.

J. P., 50 years old, sailor by occupation, married. Family history negative. Previous condition of health: He had typhoid fever when 4 or 5 years old. During the late war, while serving in the Navy, he was confined to his bed with rheumatism for nine months and at another time for four months. No history of tuberculosis in the family. He denies any syphilitic taint. He had malaria at about 20 years of age.

Condition before operation: His present illness began about five years ago. Since then he has been annoyed by chronic inflammation of the bladder. He found it necessary to void his urine four or five times during the night and the act of micturition

was accompanied by sensations of scalding or burning. His bowels have been constipated all the time, and he has slight gastric disturbance. About four years ago, slight spinal curvature began, being principally marked in the dorsal and lumbar regions. He finds it necessary to use a cane to support himself on account of his deformity. He has lost considerable flesh and complains of much pain of a neuralgic type, which radiates from the left lumbar region to left thigh and leg. About two years ago he noticed a "lump" in his abdomen which he could move around in various directions, and which he found gave him no trouble when it was pushed up under the left ribs as he expressed it. He stated that when he squeezed it a sickening pain was felt. After awhile he found that a canvas belt with a large pad on the inside of it kept the "lump" up in the left lumbar region. He said that occasionally this lump would slide down under the belt and being squeezed would cause him a great deal of distress. For a long while he has been unable to control his bladder and has found it necessary to wear a rubber urinal.

Bi-manual examination revealed a movable kidney, the outline of which could be easily made out as his abdominal walls were very flaccid.

An examination of his urine revealed pus and triple phosphates. A search was not made for tubercle bacilli. His spine was strongly curved to the right. Possibly there was some ankylosis of the lower dorsal vertebræ. The patient had no recollection of acute symptoms of spinal disease. His skin was dry and had a dusky hue.

Treatment previous to operation: I recommended him to drink freely of flaxseed tea and prescribed salol and boric acid  $\bar{a}\bar{a}$  5 grs., to be taken in a glassful of water (boiled) or in flaxseed tea every four hours during the daytime. I taught him how to pass a soft rubber catheter No. 9, and directed him to use it four times daily and told him to empty the bladder before retiring for the night.

A special apparatus was secured for him, with a suitable pad attached on the left side to keep the kidney in place. This failed to give him relief, *e.g.*, to support him as he desired, and so it was discontinued. He found that his old belt worked better. His bladder improved steadily and his annoyance at night almost disappeared.

He urged me to operate and either remove the kidney or fasten it in its normal position, and so I made the necessary arrangements. The indications were:

1. To relieve annoying pain, resulting from the kidney being squeezed.
2. To relieve bladder symptoms by straightening the ureter and relieving symptoms resulting from irritating urine in it and in pelvis of kidney.
3. Possibly to relieve weight from bladder and pressure upon bowels.
4. To possibly favor treatment of the spine.

Operation March 3, 1893: Chloroform anesthesia. The usual colotomy incision was made, the kidney pushed into its normal position, the capsule opened about one inch and the edges of the incised capsule sutured with silk sutures to the edges of the wound on either side, drawing the edges of the cut capsule as far outward as possible.

Three long silkworm gut sutures were passed through the kidney substance and through the muscles and fascia some distance from the edges of the

wound on either side and tied after inserting a twisted silkworm gut drain in the lower angle of the wound. The balance of the wound was closed with silkworm gut interrupted sutures, taking care to approximate the edges of the skin incision as neatly as possible. Beta-naphthol was sprinkled over the line of incision and bichlorid gauze and cotton applied. The patient made an excellent recovery.

Subsequent treatment: After the wound closed I decided to try and improve the condition of his spine. I advised Sayre's suspensory apparatus which he has used faithfully with good results. He is now more erect, the spinal curvature less marked and he feels better.

Once a week for about two months I washed his bladder out with silver nitrate sol. 2.5 per cent. This improved the condition of this organ very much, as he hardly ever expressed the desire to void his urine during the night after this treatment was begun.

He used the interrupted and continuous currents for some time and felt better, but electricity did not seem to assist the bladder as much as the silver nitrate sol. He now has some control over the bladder and can retain a moderate amount of urine. At night there is not the old inclination to void the urine, and taking everything into consideration, I feel that the operation has helped his condition a great deal.

#### DISCUSSION.

DR. D. W. GRAHAM—I would not consider in this case that the spine was in any degree the cause of the movable kidney. The Doctor is silent as to the pathologic condition of the spinal column; whether this was what we call scoliosis or whether it was disease of the vertebræ. But I do not see how the curve could be a cause of the condition of the kidney, although possibly it had something to do with it. In regard to the indications for operation, I think they were very clear in this case. It is in just this class of cases where anchoring the kidney to the muscles of the loin is followed by relief of symptoms and is of benefit to the patient. In the large majority of cases the right kidney is the movable one. I have had two cases of movable kidney on the left side; one this afternoon, and it seems to me in these two cases and the one reported tonight that the symptoms are more pronounced than when the right kidney is involved. I have seen a good many cases of movable kidney on the right side, but only one in which the symptoms were as pronounced and affected the health of the patient as much as in these cases of movable left kidney. We know that there are a great many cases of movable kidney, in which there is no necessity or indication for operation as far as symptoms are concerned. I have in mind a number of such cases. So it is not simply the presence of a movable kidney that calls for operation; it is the group of symptoms and their severity. The Doctor speaks of the kidney pressing on the bladder; that may be correct; it is possible. In one case where I operated the kidney was found hanging over in the pelvis, lying between the common iliac vessels. However, I did not determine that to be the kidney until I had opened the abdomen through the middle line. I then sewed up the wound and through an incision in the loin anchored the kidney in place. We know that the symptoms of cystitis and the symptoms the Doctor has described, as due to pressure of the kidney, may occur in any of these severe cases without having the kidney press upon the bladder. I am inclined to think the Doctor has drawn a wrong inference there.

As to the method of operating, there are three chief ones: one is simply stitching the fatty capsule to the muscles of the loin, but that method is being and should be abandoned. The other two methods differ a little in detail; one simply brings the kidney up against the wound and sutures it with two to four sutures through its substance to the borders of the incision. The other method consists in incising the fibrous capsule for a distance of an inch or an inch and a half and suturing the incised border of the capsule to the tissues. I prefer, having opened the capsule, to suture the edge of the fibrous capsule to the border of the muscle with absorbable sutures and then sew up the wound. I have seen a good many use silk and silkworm gut sutures to stitch the kidney to the lumbar wall. I do not understand why this is still

persisted in, because in the large majority of cases this material causes trouble; it leaves sinuses, and the stitches have to be removed at some future time. I am satisfied that it is not a question of the aseptic condition of the suture, because if one careful person can render silk or silkworm gut aseptic, another careful person can usually do it. With the help I have, I believe I can render silk or silkworm gut as aseptic as anybody can, and yet in the majority of cases where I bury silk in the tissues it gives rise to a sinus from which these sutures have to be removed. I am satisfied that the greater number of buried sutures of silk or silkworm gut require removal later. I am not speaking of the peritoneum, but of other tissues.

DR. GAVIN—In regard to the spine producing the movable kidney, Dr. Graham misunderstood me. I considered the curvature of the spine as tubercular in nature, and having caused the consumption of nearly all the fat of the body a lack of support to the kidney resulted. When I exposed the kidney there was very little fat about it, and I thought it extremely probable that the general wasting process favored the movable state of the kidney. I did not use catgut because I had no preparation that I could rely upon as being perfectly aseptic. I used buried silk sutures to connect the muscles together. I did not intend to state that I brought the skin directly in contact with the capsule, but the object was to bring the edges of the cut capsule as near the surface as possible and allow it to adhere to the muscular structure. The skin incision proper was closed with silkworm gut sutures, which were removed at an early date.

DR. SANGER BROWN—It appears to me that this is a very interesting case, but it is rather puzzling to get any satisfactory explanation of the relation between the spinal curvature and the kidney. I did not quite understand from the Doctor's paper that it was demonstrated the patient had tuberculosis, and it occurred to me in trying to think of cause of the curvature, that possibly the movable condition of the kidney and the irritation set up by that might excite atrophy or wasting of the muscle and in some way unfavorably affect the nutrition of the intravertebral substance, and in that way the spinal curvature be accounted for.

DR. A. E. HALSTEAD—I believe the ordinary explanation of cystitis in such cases is that the hydronephrosis which is usually present in movable kidney is always infective. I think that would explain all the bladder symptoms in this case. When the Doctor changed the position of the kidney and straightened out the ureter, the bladder symptoms disappeared, because the hydronephrosis was drained. I do not see any relation between spinal curvature and floating kidney.

DR. GRAHAM—I did not understand whether the Doctor's patient has tuberculosis of the vertebræ or any other disease of the bones.

DR. GAVIN, in closing the discussion, said: The patient had no active disease at the time I saw him; there was no evidence of a collection of pus. I thought possibly there might be a tubercular process in the bodies of the vertebræ.

## A CASE OF PAPULAR SYPHILIDE OF THE CONJUNCTIVA.

Read before the Chicago Pathological Society, Jan. 14, 1895.

BY W. FRANKLIN COLEMAN, M.D.

PROFESSOR OF OPHTHALMOLOGY, POST-GRADUATE MEDICAL SCHOOL OF CHICAGO.

As several of my confrères have never seen a secondary syphilitic lesion of the conjunctiva, and since, until recently, no case has come under my own observation, the disease seems sufficiently rare to demand that every instance of it be put on record.

Before reporting our own case, we will take a glance at the literature of the subject, to illustrate the infrequency and the nature of syphilitic disease of the conjunctiva (especially secondary lesions) and will refer chiefly to Bull's excellent resumé in 1878, and to writings indicated under the head of "Diseases of the Conjunctiva" in the "Index Medicus" from its first issue (1879) to date.

The following is taken from a paper by Charles Stedman Bull, M.D., in *American Journal Medical Sciences*, October, 1878:

"Syphilitic lesions of the conjunctiva, existing independently, and not connected with lesions of the eyelid on the one hand, or the eyeball on the other are not common. The syphilitic lesions of the conjunctiva are eruptions, ulcerations and infiltrations. Under the head of ulceration are the chancre and secondary ulcers resulting from the breaking down of infiltrated masses. According to Sturgis in his report of 1,646 tabulated cases of chancre, the ulcer occurred only six times on the eyelid. In some of the cases, the ulcer was purely a conjunctival lesion. Demarres had in his practice two cases of chancre of the conjunctiva, one palpebral, another in the inferior cul-de-sac.

Galezowski reports six patients with chancre of the conjunctiva, and Sturgis, Bumstead, Dietlen, and Bull one each.

An instance of syphilitic conjunctival disease is quoted from Smee, who calls it "conjunctival blotch," and three similar cases are given from Mr. French.

Lawrence cites two cases of general papular eruption in which there were a few pustules on the mucous membrane of the lids.

Bull says he has seen several cases of ulcerated mucous patches of the conjunctiva, and reports one. He remarks that secondary lesions of the conjunctiva, those occurring during the period of constitutional infection, are much more frequent than the initial lesion.

The papular syphilide at least, if more frequent than the chancre, is much less often reported. Bull does not quote a single case in his very full paper, and the "Index Medicus" gives only one by title.

A third variety of conjunctival lesion in constitutional syphilis is the gummy infiltration, and this is probably the least common of all.

Descriptions are given of conjunctivitis gummosa in the practice of Tavignot, Magnin, Hirschberg, De Wecker, Estlander, Brière and Bull.

Galezowski affirms that syphilitic affections of the conjunctiva are either chancres or mucous patches. If he intends to assert that the latter are identically the same as papules, the authority of Keyes will support it.

Laucereaux describes secondary lesions of the conjunctiva as small circumscribed spots, elevated, of a reddish gray or coppery color, not differing much from certain eruptions on the skin with which they may co-exist.

"The 'Index Medicus' refers to some thirty papers on the primary (ulcer) and tertiary (gumma) lesions of the conjunctiva, but to only one by title on the secondary (papular) lesions, viz., *Les papules syphilitiques de la conjunctive*."—*Gaz. Med. de Paris*, 1894, 9, s. I., 196–198.

Bull, writing on "System of Genito-Urinary Diseases, Syphilology and Dermatology," by Morrow, 1893, divides the syphilitic diseases of the conjunctiva thus: conjunctivitis; secondary lesions; mucous patches; ulcers; gummata.

Loring, in a chapter contributed to Bumstead on "Venereal Diseases," 4th Ed., says: "The ocular conjunctiva is very rarely the seat of syphilitic manifestations." He quotes from Savoy, (Paris, 1876), a case of syphilitic papule developed upon the ocular conjunctiva 3 m.m. above the cornea. The patient contracted syphilis six months previously, and had a lenticular eruption on the whole body. Two similar cases are given from Horteloup and Laibler.

Secondary syphilis gives rise to secondary skin affections of the conjunctiva, which attend it on other parts of the body. (Swanzy, "Diseases of the Eye," 1892).

In cases where the face is the seat of papular or tubercular eruptions, a corresponding condition may at times, though rarely, be observed upon the lining membrane of the lids (De Wecker). The papular syphilide appears from the third to the sixth month. Unless they ulcerate, the papules leave no scars. They frequently leave pigmented areas behind (Keyes).

The following notes of my case are incomplete, as the patient unexpectedly discontinued his attendance:

N. T., age 24, male, colored, came to my clinic at the Charity Hospital in November, 1894, on account of an inflammation of the left eye, which had somewhat annoyed him for a week, with a feeling as if something had got into his eye. At the limbus of the cornea were four nodules implanted in the conjunctiva; one on the nasal side, one on the temporal, and two below and within 3 m.m. of each other. The lateral nodules were 4 m.m. in diameter by 2 m.m. in height. The lower 3 m.m. in diameter by 2 m.m. in height. All circular, with a finely granular apex, and of the red color of granulation tissue. The papillary reaction, the iris and the cornea were normal. V = 20-50. The refraction was not tested. In the vicinity of the nodules there was moderate hyperemia of the conjunctiva. Very little pain had been complained of. Two very small ulcers (1 m.m. in diameter) were situated on the outer third of the anterior edge of the upper lid. The pre-aqueal glands were not enlarged. A history was given of the appearance on the face, at the age of 13, of an eruption which disappeared and left no pitting and relapsed once in about three years. During July last he contracted a chancre, which was followed by swelling of the inguinal glands, and a secondary papular eruption on the skin. The cheeks and forehead presented a thickly covered, mixed acne-like and papular eruption, arranged here and there in somewhat irregularly concentric groups. Numerous depressed hyper-pigmented scars were scattered among the papules. The covered parts of the body were not examined.

During the second week of treatment the papules of conjunctiva diminished one-half in size, and around the two lower edges of the conjunctiva a pigmented zone was first seen.

The diagnosis of a secondary papular syphilide of the conjunctiva was based upon the syphilitic history of the case, the associated papular syphilide of the face, the exclusion of other lesions of the conjunctiva, and the rapid resolution of the nodules without ulceration under the mixed treatment and the application to the eye of an ointment of hydrarg. ox. rub. grs. ii, vaselin 3j rubbed in for five minutes daily, by massage of the lids.

The patient was referred to Dr. Baum, Professor of Dermatology, Post-Graduate Medical School, who confirmed the diagnosis and prescribed the constitutional treatment. The rapid progress toward recovery (in two weeks) probably accounts for the early vanishing of the possessor of our rare specimen.

#### DISCUSSION.

Dr. C. D. Wescott—As Dr. Coleman has said, these cases are very rare; it has never been my fortune to see one such as the Doctor has described. The only syphilitic lesions of the conjunctiva I have seen are the simple chancre, of which I have seen one case, and one case of gumma. It does not seem possible that there can be an error of diagnosis in this case. I do not know of anything that affects the conjunctiva which would give a similar appearance, even without the confirmative syphilitic history and other lesions. I congratulate the Doctor on having had an opportunity to observe such a case.

Dr. F. W. Coleman—I would say with regard to chancre that they are not so very infrequent upon the edge of the lid, and chancres upon the lids might be easily mistaken for epitheliomata. I have had the misfortune to remove from the lid what I thought was an epithelioma and had a chancre turn up very near it within ten days, which was cured

with iodid of potassium. This case, by the way, was diagnosed by the syphilologists as an epithelioma. Gumma is not so rare although it seldom manifests itself in the conjunctiva, but not so rarely in the iris and ciliary body involving the sclera and therefore appearing externally as a nodule. That the Doctor does not refer to. The gumma that limits itself and is situated primarily in the conjunctiva is an excessively rare disease. Up to 1878 Bull makes a resumé of all the cases he has had access to and describes them fully, but does not describe a single case of papule. The "Indicus Medicus" from 1879 to date only records a single case by title of papule of the conjunctiva.

Dr. C. W. Hawley—Speaking of gumma of the conjunctiva reminds me of a case I saw in a hospital in Europe, which was diagnosed gumma of the conjunctiva and was treated with mercurials very faithfully for a long time, but it did not seem to improve and finally the surgeon concluded to operate upon it. When he made his incision through what he at first supposed was a gumma he removed three pieces of putty. It was impossible to get any history of how the putty came there, the patient said she did not know; either she did not want to tell or did not know how it got there.

### A CASE OF TACHYCARDIA COMPLICATING CHLOROFORM ANESTHESIA.

Read before the Louisville Academy of Medicine, March 18, 1895.

BY HENRY E. TULEY, A.B., M.D.

CLINICAL ASSISTANT TO CHAIR OF PRACTICE KENTUCKY SCHOOL OF MEDICINE; VISITING PHYSICIAN TO THE MASONIC WIDOWS AND ORPHANS' HOME, ETC.  
LOUISVILLE, KY.

The following is the report of a case of tachycardia, complicating chloroform anesthesia. The man was a patient of Dr. Mathews, and was to be operated upon for fistula. He was about 30 years of age; a strong, vigorous man, and a good subject for chloroform anesthesia. The following previous history was detailed after his regaining consciousness. He had had repeatedly, attacks of heart trouble, a greatly accelerated heart's action being the chief symptom, with once or twice loss of consciousness during the attack. He is a slave to smoking, using the strongest tobacco, uses liquor sometimes to excess and drinks strong coffee. Face was florid, but heart's action normal, pulse 84, with no organic lesion. He was very nervous when he got on the table, and asked that his heart be examined but said nothing of his previous history. The anesthesia was begun at 3:06 P.M., with chloroform, on the Esmarch inhaler, drop by drop method. The exciting stage was quite severe, the chloroform was pushed and in three minutes he was relaxed, it having taken 2 5-10 drachms to bring him to the surgical degree, taking fourteen minutes; in all 5 drachms were used.

The operation was begun at 3:20 P.M.; the pulse and respiration were normal. At about 3:42, after the operation was nearly completed, the chloroform mask was removed, as the pupils were well contracted and the patient fully anesthetized. At 3:44 without any warning whatever, the pulse from an even regular one of about 80 or 90 suddenly began beating too fast to count, more than 200. The respirations remained unimpaired. We administered 1-100 grain of nitroglycerin hypodermatically, the dressing was hastily applied and the patient put to bed. While his pulse was in this condition and before he was removed from the table he raised his head and said: "Well, I'm glad I'm through with that chloroform." During the next hour 1-25 grain of nitroglycerin was administered, 1-100 grain of atropia and 1-32 of strychnia, without any effect as to lessening the rapidity of the heart beats. Hot water bags were applied to feet, and over the heart. Only at one time, and then for only four or five minutes, did he complain of dyspnea. He was convinced of the fact that he was going to die. The radial pulse all of this time, one hour, felt as if there were a constant current of blood under your finger, no pulsation was distinguishable, but the ventricular contraction was easily made out, much too rapid to count. His respirations were unimpaired, breathing through his nose, skin relaxed and moist, mouth dry from the atropia and finger nails pink. He was seen at 4:20 by Dr. Marvin in consultation; ¼ grain of morphia was given at his suggestion hypodermatically, ice was substituted over the precordia, and in twenty minutes the pulsations could be felt, not counted at the wrist, but the ventricular contractions could be counted 160 to the minute. His pulse remained in this condition until 7 P.M., when it

again became rapid, beating 200 to the minute. A second dose of morphia,  $\frac{1}{4}$  grain was given hypodermatically, and at 8 P.M., his pulse was 97, and the patient sleeping quietly, having vomited some water which had been taken in the shape of crushed ice. During the night he slept at intervals and the hourly pulse was as follows, beginning at 7 P.M.: Two hundred, 97, 98, 92, 88, 80, 80, 81, 78, 78. At midnight one teaspoonful of aromatic spirits of ammonia was given.

The case seems to be a unique one as well as instructive. Here was a man who apparently was a good subject for anesthization and without warning the above complications arose. It teaches us that the rule laid down by most authors as to the careful watching of the respiration alone is erroneous. Had this man's condition not been noted, and the operation only partially completed, and had more chloroform been given, I believe he would have died. Hence the practical conclusion, watch the heart always, as well as the respiration. The second lesson is the danger of being too zealous in the application of restoratives, owing to anxiety as to the safety of your patient. There was in all probability too much given this man.

This case is entirely unique in the writer's experience, nor have I seen any such case in the literature of the subject.

#### DISCUSSION.

DR. BAILEY—The subject of anesthesia is a big one. As to the case reported, I would criticise it first, because Dr. Tuley said the patient was a vigorous healthy man; I find these the worst cases. I think his condition was peculiar and not developed by the anesthesia in the light of his present condition.

There was a bad nerve force present. As to the management of the case, with the rapid heart, nitroglycerin should not have been given. I should rather have chosen digitalis or digitalin because of its influence on the inhibition. I should have used moderate doses of morphia—should not have ventured 1-4 grain but have given 1-8 grain and waited for effects.

I think constantly of the possible evils of the Hyderabad Commission, in recommending that the respiration be watched and not the pulse. Notwithstanding that report, I am more anxious to watch the pulse, and I endeavor to look after both. I disregard the pulse in etherization, but not in chloroform. I am sure I have given chloroform in more than one thousand cases, and I am firmly convinced of that fact.

DR. F. C. WILSON—The case reported is an interesting one and shows the necessity of careful watching. To watch the pulse and respiration both, the anesthetist has his hands full. He should also watch the countenance. Anesthesia must be profound in operations upon the rectum, and because of that fact the danger is enhanced. If the previous attacks had been known in this patient, in all probability the case would have been watched for a recurrence, but I doubt if the case could have been watched more closely, or the tachycardia noticed earlier than was done by Dr. Tuley. Like Dr. Bailey I should not have given nitro-glycerin, but think that digitalin was indicated; strychnia also, as was given, morphia and perhaps spartein; the latter given previous to the administration of the anesthetic fortifies the heart, and those cases in which I have used it have done well, the heart maintaining its strength throughout the anesthesia.

DR. BAILEY—I would like to state that as to complete anesthesia, it is difficult to bring anesthesia to a proper stage for division of the sphincter, and there apparently is pain. Lauder Brunton said that no operation should be done unless there was complete anesthesia. It may be possible that the case was not fully anesthetized, and the reflex caused the tachycardia. No operation should be done unless the anesthesia is complete.

DR. VANCE—I believe that in local anesthesia the shock is not so profound. We used to see great shock from the removal of a toe nail under general anesthesia. Since cocaine has been introduced we see less of it, the nerves are benumbed locally, and they are prevented from transmitting any shock. I believe that all operations should be done under complete anesthesia. The greatest accidents are

when we operate under primary anesthesia. Local anesthesia proves that the shock is reflex, as it is in the division of the rectum.

DR. W. C. CHAPMAN—It has been noticed how frequently tachycardia occurs in tobacco users. I never examine tobacco users that I don't find them with a pulse rate of ten to twenty above normal. Tachycardia is not present at all times, and may be brought on by other causes, as a latent malaria may develop after a surgical operation, so an indigestion and excesses may cause tachycardia.

DR. DUGAN—I have had two fatal cases under chloroform anesthesia. Neither used tobacco, for they were both ladies; both occurred within a week of each other. The first one was an operation for ovariectomy; there was only one inhalation, the patient called for "a candle, a candle," being a Roman Catholic, in one breath. The lips became livid, the heart's action stopped. I thought that perhaps it was partially from pressure by the large tumor, and plunged my knife through the abdominal wall and relieved that by letting out the fluid, but the patient never rallied. This case was on Sunday, and the following Tuesday I wished to divide a rectum for fissure. The patient was not excited, her heart was good, pulse regular. She was rather inclined to be fat, but took the anesthetic like a baby. When Dr. Guest said she was ready, I introduced my thumbs and divulsed; there was no pain, no resistance, chloroform was withdrawn, and the patient was sponged off. In half a minute, Dr. Guest seemed concerned, and said the patient was not breathing well. I noticed some lividity of the face. She was suspended, artificial respiration performed, and at no time during the forty-five minutes we worked with her did she show pulse or respiration. She was healthy, a non-tobacco user, and drank little tea or coffee. We can not tell when these cases will do badly. The shock could not have been due to the division, and Dr. Guest estimated that only 30 minims had been used altogether.

DR. J. B. BULLITT—Dr. Wright, of Bowling Green, has in the last few months reported several cases of the new-born asphyxiated, in whom respiratory effort was established by the introduction of the tip of the index finger in the anal orifice, producing thereby a dilatation of the sphincter. There was complete asphyxiation, absolutely no respiratory effort, but immediately on dilatation of the sphincter and respiration was established and the infant began to cry lustily. He also suggested the adoption of similar means to restore respiratory effort in unfortunate cases of anesthetization. This fact would appear to throw some light on the subject in hand. It is generally conceded that death from chloroform occurs primarily from respiratory failure, the heart failure being secondary. It hardly seems probable that dilatation of the sphincter and could produce respiratory effort on the one hand (asphyxia neonatorum) and yet produce a paralysis of effort on the other (chloroform narcosis). There seems to be here an incompatibility of effects. It would seem probable, that what really happens is this: division of the sphincter before narcosis is surgically complete causes deeper respiratory effort, thereby a largely increased amount of the anesthetic is thrown suddenly into the circulation, so that the centers are overwhelmed and respiration suddenly ceases. It is not the "shock" *per se*, that has done the mischief, but its respiratory effects. In such a case, if the anesthetic were withdrawn and the division of the sphincter and again practiced, it would seem quite probable that respiratory effort would again be stimulated as suggested by Dr. Wright.

DR. RODMAN—We never know when accidents will occur. If deaths are more likely occur from partial anesthesia, why do they not occur without any anesthesia in minor operations? Certainly if a little pain is so dangerous, we would have many deaths where no anesthetic is given. I do not believe Dr. Bailey's explanation the true one. I think it is best to have light anesthesia in the condition of shock. I am satisfied that the danger is in proportion to the amount of chloroform vapor in the blood at any given time. There have been more deaths reported in the last few years than ever before in the history of chloroform. In Germany, chloroform used to be given almost exclusively, but ether is now being extensively used. There have been five or six deaths in Louisville in the past eighteen months from chloroform, and there were none for five years previous that I remember. It may be that the chloroform we use now is not so good, but the chemists say it is better. A statement was made recently by the Professor of Therapeutics in the Johns Hopkins Hospital, that if we give chloroform to a dog once it bears it well, and will have no bad effects, but if it is given the second time it kills, but this is not so of ether.

Hare, in a paper on chloroform, makes the statement that instead of lowering the head it should be thrown forward as that position opens the epiglottis. Notwithstanding chloroform has been a favorite in Louisville for so many years. I am an advocate of ether. It can be incontestably shown that ether is safer than chloroform:

DR. I. N. BLOOM—The history of anesthesia shows ether to be the safer. It is rare that death occurs in complete anesthesia. Statistics will prove this.

DR. DUGAN—I would like to add that I saw a patient operated on by Dr. Weir for a nephrectomy, die under the anesthetic, having taken it twenty-one times before.

DR. TULEY—I simply want to state that nitro-glycerin was given in the case reported, because there was a good effect noticed from it, in that the pulsations at the wrist could be felt after each dose. Digitalin was thought of but none was at hand. The divulsion was practiced without causing any impression upon the patient.

## THE NORMAL SITUATION OF THE GALL BLADDER IN MALES.

BY JOHN B. HAMILTON, M.D.

CHICAGO.

To find the gall bladder, draw a line from the anterior superior spinous process of the ilium to the center of the xiphoid appendix. Intersect this with a line from the umbilicus to the tenth costo-cartilaginous junction.

tion. In the right upper triangle near the apex, but nearer the right oblique line, the fundus of gall cyst will be found. A needle thrust through the abdomen at the point indicated, will usually transfix the gall bladder. The position of the gall bladder varies with the changes in the position of the liver; in enlargements it is pushed downward, and in some cases deflected to the right.

## ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.  
NEW ORLEANS, LA.

(Continued from page 520.)

### CHAPTER VIII.

#### EFFECTS OF JAUNDICE UPON THE FREQUENCY OF THE PULSE.

Case 1.—Malarial fever, dysentery and jaundice. A. F., age 32; native of Germany. Entered Charity Hospital Dec.

29, 1875. Had had intermittent fever. Says that he has been sick with intermittent fever and dysentery for fourteen days. Upon entrance presented a pale sallow, bloodless hue, and suffered from painful discharges from the bowels, of mucus and blood at regular intervals. On January 1, the patient showed a distinct yellow tinge of the skin and conjunctiva of the eyes, which gradually increased to the most intense jaundice in the course of ten days. The urine was heavily loaded with bile, but free from albumin. The pulse which had been rapid and feeble, ranging from 100 to 120, became much slower after the supervention of the jaundice. The effect of the bile in the blood upon the frequency of the pulse is shown in the following table:

Date.	Pulse.		Resp.		Temp.	
1875	M.	E.	M.	E.	M.	E.
Jan. 13	...	70	...	...	...	99 °
14	...	70	...	32	...	101
15	...	80	...	36	...	100
16	70	80	28	32	99 °	101
17	100	100	24	32	101	104
18	80	92	32	32	98	102
19	70	92	24	32	99.5	103.5
20	72	80	28	36	99.5	103.5
21	80	88	20	20	98.5	103.5
22	76	84	24	24	99.5	101
23	76	72	32	24	99.5	100.5
24	72	68	28	28	99.5	100
25	...	80	...	20	...	99.5
26	72	72	36	40	97.5	98.5
27	72	76	40	36	99.5	99
28	60	72	36	32	98.5	100
29	72	64	32	32	99	99.5
30	60	64	28	36	99.5	100
31	...	68	...	32	...	99
Feb. 1	68	68	40	32	99.5	99.5
2	68	...	32	...	98.5	...

The periodic variations of the temperature in this case were regarded as the result of the action of the malarial poison. It will be observed that in this case after the supervention of jaundice, the pulse was only 100, with a temperature of 104 degrees F., and on January 20, the pulse was only 80, with a temperature of 103.5 degrees F. On the 30th the pulse was only 60, notwithstanding the continuance of the dysentery, with frequent discharges from the bowels.

The treatment of this case consisted mainly in the rigid adherence to milk and rice diet and beef tea, and the employment at regular intervals of a mixture of quinin, subnitrate of Bismuth and Dover's powder; in the proportion of 3 grains each of quinin and Dover's powder, and 10 grains subnitrate of bismuth, every three, four or six hours. These powders were also alternated with a simple mixture of syrup of morphia and subnitrate of bismuth, or with a mixture composed of equal parts of the tinctures of catechu, opium, camphor, capsicum and Peruvian bark, a teaspoonful in a wineglass of water every three or six hours. Port wine and alcoholic stimulants in small quantities were also found to be beneficial. This was a protracted and tedious case, but the patient was finally restored to health and was discharged in the month of March.

Case 2.—Malignant scarlet fever attended with jaundice; slow pulse, recovery. Adam Grethiel, age 19; native of New Orleans. Entered Charity Hospital Feb. 11, 1876. February 11, deep scarlet eruption; where the eruption is not very great the skin presents a yellowish tinge. Conjunctiva of eyes yellow. Mucous membrane of throat and tonsils swollen and ulcerated. Tongue dry and red; patient swallows with difficulty; hemorrhage from the mouth and gums; wild delirium; necessary to confine the patient to bed. Has been sick about one week. Abscesses are beginning to form near the elbows and at the extremities of the fingers; P.M., pulse 100, respiration 48, temperature 103.5. February 12, A.M., pulse 100, respiration 36, temperature 102; P.M., pulse 108, respiration 28, temperature 103. Desquamation is beginning, and as the scarlet color diminishes, the deep yellow color becomes more manifest. February 13, A.M., pulse 100, respiration 36, temperature 100; P.M., pulse 124, respiration 36, temperature 103.5. February 14, A.M., pulse 88, respiration

tion 28, temperature 100; P.M., pulse 100, respiration 32, temperature 99. The pulse continued to decline in frequency and on the 16th was 72, with a respiration of 24 and temperature 101. It would consume too much space to present the numerous details relating to the pulse, respiration and temperature in this case; the pulse, however, continued to grow slower notwithstanding the condition of the throat and the formation of abscesses and on the 19th the pulse was 68, respiration 24, temperature 101; on the 22d, pulse 64, respiration 20, temperature 100.5. The patient finally recovered entirely.

*Case 3.*—Pneumonia, with intense jaundice; albumin and bile present in the urine, chlorids absent; frequency of the pulse diminished by the bile in the blood. John T. Webb, age 37, native of Maryland. Has resided in New Orleans for eighteen months. Entered Charity Hospital January 8 in a restless sleepless state and apparently suffering from alcoholism. Patient states that he "had been drinking very hard before entering the hospital." The bowels were opened with the compound cathartic pill (U. S. P.), and the nervous agitation was measurably relieved by bromid of potassium in combination with liquor ammoniac acetates. On January 10, the patient complained of pain in the right side, with cough and oppression of breathing. Dullness upon percussion, with crepitation over lower and middle lobe of right lung. Pulse and respiration greatly accelerated, temperature elevated. January 11, evident marks of pneumonia of right lung; the conjunctiva of eyes and skin present a distinct yellow tinge. January 12, jaundice well marked, high fever, pulse decreasing in frequency, falling from 130 to 112. Bile and albumin present in urine, chlorids entirely absent. There is no hepatic tenderness.

January 13, cough, pneumonic sputa, headache, pain in back and limbs; no hepatic tenderness, albumin and bile in urine, chlorids absent. Skin of a golden yellow color, conjunctiva of eyes yellow. Patient complains of great depression of spirits and restlessness. At 8 A.M., pulse 100, temperature of axilla 101. 14th, A.M., pulse 128, respiration 32, temperature 99; P.M., temperature 102. 15th, P.M., pulse 100, respiration 32, temperature 99.5; P.M., temperature 100.5. 16th, A.M., pulse 100, respiration 20, temperature 99.5; P.M., pulse 109, respiration 32, temperature 99. 17th, A.M., pulse 108, respiration 28, temperature 100; P.M., pulse 112, respiration 24, temperature 101. 18th, A.M., pulse 88, respiration 24, temperature 98.5; P.M., pulse 100, respiration 32, temperature 101. 19th, A.M., pulse 100, respiration 28, temperature 100; P.M., pulse 100, respiration 24, temperature 102. 20th, A.M., pulse 100, respiration 32, temperature 99.5; P.M., pulse 100, respiration 28, temperature 101. 21st, A.M., pulse 84, respiration 32, temperature 98.5; P.M., pulse 88, respiration 32, temperature 101. 22d, A.M., pulse 80; respiration 32, temperature 98.5; P.M., pulse 100, respiration 40, temperature 101.5. 23d, A.M., pulse 72, respiration 32, temperature 98.5; P.M., pulse 92, respiration 32, temperature 101.

Convalescence was tedious in this case, but the patient was discharged on the 23d. In the intensity of the jaundice and in the presence of albumin in the urine this case upon a superficial examination resembled yellow fever. The effect of the bile in the blood on the action of the heart will be still further evident by comparing the variations of the pulse and temperature in the three preceding cases, with the three following:

*Case 4.*—Pneumonia of right lung, rapid pulse, rapid respiration and elevated temperature—fatal issue. Thomas Gegan, age 20, native of Ireland, baker. On Feb. 10, 1876, went to sleep on cold ground, and on awakening suffered with severe pain in the right side. Entered Charity Hospital Feb. 17, 1876. He says that he has been sick with fever and severe pain in the right side for five days. February 17, evening, pulse 140, respiration 48, temperature 105.5 F. Some pain in right side, with cough but little expectoration; sputa contains much pus mixed with the rusty colored fibroid matter. Crepitation and dullness over right lung and over lower lobe of left lung. A cavity is evidently forming in the infraclavicular region of the right lung. Percussion gives the cracked-pot sound, and auscultation reveals amphoric respiration. The purulent matter comes from this cavity in great measure. February 18, A.M., pulse 140, respiration 44, temperature 105.5; P.M., pulse 128, respiration 40, temperature 106. No albumin in urine, bile present, chlorids wholly absent; specific gravity 1010. 19th, A.M., pulse 140, respiration 36, temperature 104.5; P.M., pulse 140, respiration 36, temper-

ature 104.5. 20th, A.M., pulse 146, respiration 48, temperature 106; P.M., temperature 103.5. 21st, A.M., pulse 140, respiration 36, temperature 105; P.M., pulse 140, respiration 24, temperature 103.5. 22d, A.M., pulse 148, respiration 28, temperature 105; P.M., pulse 144, respiration 24, temperature 104.5. 23d, A.M., pulse 120, respiration 28, temperature 103.5. On the 20th the patient became delirious, with occasional lucid intervals and died on the 23d.

We might greatly multiply such cases, but they have been illustrated in the first volume of my "Medical and Surgical Memoirs."

*Case 5.*—Chronic malarial poisoning and intermittent fever, illustrating the rapid circulation in this disease. J. Hogan, age 29, native of New Orleans, carpenter, admitted to Charity Hospital Oct. 21, 1875; has been working on Baker River, Louisiana, and has suffered with intermittent fever for two months. October 23, sallow anemic complexion, presenting a dusky greenish-yellow color; has fever as in chronic malarial poisoning. A.M., pulse 122, respiration 32, temperature 103.25; P.M., temperature 102. 24th, A.M., pulse 128, respiration 36, temperature 103; P.M., temperature 101.5. 25th, A.M., pulse 130, respiration 24, temperature 101.5; P.M., temperature 101. 26th, A.M., temperature 100; P.M., temperature 102. 27th, A.M., pulse 100, respiration 24, temperature 101.5, P.M., temperature 102. On October 25 I administered to this patient, in addition to the full doses of quinin, tincture of digitalis. The reduction of the frequency of the pulse was marked and rapid. In this case with a temperature of 101.5, the pulse reached 130 beats per minute. The urine was high colored, but contained no albumin.

Case of circumscribed pneumonic pleuritis; rapid pulse; fall of pulse after effusion into pleura and lungs. George Allen, sailor, entered Charity Hospital Jan. 18, 1875. January 19, pain in left side; hurried respiration; pleuritic friction sound and crepitant râles in lower and middle lobes of left lung; delirium. A.M., pulse 150, temperature 103.6. 20th, A.M., pulse 120, respiration 45, temperature 101.5. 21st, A.M., pulse 112, respiration 36, temperature 99. The urine was loaded with urates but contained no chlorids. Albumin absent. The dullness upon percussion increased, effusion has taken place and with it the temperature has fallen and the pulse has become slower.

January 22, A.M., pulse 72, respiration 20, temperature 97.7. 23d A.M., pulse 72, respiration 25, temperature 97.8. The delirium and mental aberration continued for four days and was followed by two days of sleep and drowsiness. Patient recovered.

It will be observed that in this case of circumscribed pleuro-pneumonia the pulse was 150, with a temperature of 103.6 degrees.

*Case 6.*—Typhoid fever and double pneumonia, rapid pulse, high temperature; death on thirteenth day of disease. Thomas Feverson, age 22, native of Norway, sailor. Has been in New Orleans during the past five months; came direct from Europe. Entered Charity Hospital Feb. 1, 1876. At time of entrance had fever, which was wholly uninfluenced by quinin which was daily given for four or five days without any manifest effect. February 4, P.M., skin hot and dry; dichrotic pulse, 160 per minute, respiration 28, temperature of axilla 103.5. Dullness upon percussion over lower lobes of both lungs, with crepitant râles and rusty colored sputa. Epistaxis, delirium, subsultus tendinum. Tenderness in right iliac region, with some gurgling; bowels slightly tympanitic; stools not frequent but loose. Passed excrement and urine in bed; sordes on teeth; tongue red and dry, not furred. The tympanitis has been greatly relieved by turpentine stupes over chest and abdomen. Chlorids absent from urine; high color. Albumin present in small quantities in urine. February 5, ninth day of disease, morning, pulse 100, respiration 24, temperature of axilla 100. February 6, tenth day of disease, morning, pulse 100, respiration 20, temperature 100; P.M., pulse 112, respiration 32, temperature 104. 7th, A.M., pulse 120, respiration 36, temperature 102; P.M., pulse 130, respiration 40, temperature 106. 8th, A.M., pulse 120, respiration 40, temperature 103.5; P.M., pulse 136, respiration 48, temperature 106. 9th, A.M., pulse 160, respiration 40, temperature 104. Patient died February 9, at 12 M.

Autopsy twelve hours after death. Thorax: Heart normal, cavities contained no blood. Lungs: right lung did not collapse when the pleura was opened; lower lobe in second stage of pneumonic inflammation, left lung adherent to walls of chest by old pleu-

ritic effusion. Lower lobe like that of right lung, congested and solidified and in second stage of pneumonic inflammation.

Abdominal cavity: liver, spleen and kidneys normal. Gall bladder distended with bile. Peyer's patches in ileum, prominent with ulcerations; solitary glands of small intestines and especially of ileum enlarged and ulcerated. White deposits in Peyer's gland and solitary glands.

In a case of yellow fever, which terminated fatally in the month of November, in the ward directly opposite to the one in which the preceding case was located, the temperature on the third and fourth day of the disease reached 104, while the pulse never exceeded during this period 100. This case (Martin H. King, a native of Ireland, age 26) terminated fatally on the fourth day; and the post-mortem examination revealed the characteristic lesions of yellow fever; fatty yellow heart, liver and kidneys; black vomit in stomach; mucous membrane of stomach highly congested.

(To be continued.)

## SOCIETY PROCEEDINGS.

### Proceedings of the First Meeting of the American Academy of Railway Surgeons.

Held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.

(Concluded from page 448.)

#### The Academy then discussed the subject of INJURIES OF THE TENDONS IN RAILWAY ACCIDENTS.

THE CHAIRMAN—Inasmuch as none of the essayists are present, we will proceed to a general discussion on this subject. Nothing troubles me more than injuries of the tendons. I want to hear what the members have to say. I expect to get some wheat and a lot of chaff as usual, but I will try and save the wheat.

DR. R. HARVEY REED—There is no question but what the subject of injuries of the tendons is one that is important to the railway surgeon. I do not think in any of the previous meetings of railway surgeons that I have attended in this country that this question has been discussed. Not a paper has been written on the subject, and yet at the same time the surgeon every now and then encounters a case of injury to the tendon that gives him more or less trouble. A traumatism to a tendon is bound under ordinary circumstances to give permanent injury, and where permanent injury occurs to a person riding on a railroad it usually means damage and loss of money to the company. We may have a tear of the tendon from its insertion; we may have a rupture in the body of the tendon itself. These are the two most frequent injuries I have met with or that are taught in our text-books, although there are other varieties, but in the treatment of injuries of tendons our text-books nearly all advise placing the arm or leg in a position in which the muscles can be relaxed, placing the tendon in the most relaxed position and keeping it there until the reparative process takes place. In my experience that is absolutely impractical, and I think if we rely on our success in treating cases in this way we will find ourselves defeated in our object. In the first place, you can not hold any tendon of any consequence in its place by a bandage. In the second place, if you bandage the tendon tight enough to come near holding it you cut off the circulation and if you do that you interfere with nature's process, and you can not have a normal reparative process. We recognize this as an important matter and one which we should seriously consider. When we have a simple tear of a tendon we should make it a compound injury instead of a simple one. With the present advantages offered us by antiseptic and aseptic surgery, I think we are justifiable in making a simple injury of this kind a compound one. It is our duty to explain to the party injured the importance of doing so and the danger of permanent injury if it is not done. If we had a tear, a fracture, a solution of the continuity of the tendon in the middle part of it, we may have so much contraction as to be unable to bring the two ends

of the tendon together. Then what are we to do? We are taught to build a bridge of catgut between the two points and we would expect a reparative process to go on the same as in bone or sponge grafting. We bring the two ends of the tendon together with catgut and therefore aid the reparative process and fill up the space with connective tissue. The difficulty with this method is to get your catgut sufficiently strong so that it will bear the tension brought on it by the muscle—i.e., the biceps or the gastrocnemius, as the case may be. It is quite difficult to get enough catgut interlaced to hold the tendon solid without destroying so much tissue in the tendon as to impair or even prevent the reparative process and thereby induce sloughing of the ends of the tendon. If you get the catgut to remain in its place you are liable to have adhesions of the sheath of the tendon, and are liable to set up thecitis, and have these adhesions extending from the sheath of the tendon to the muscles, thus impairing the activity of the tendon which we desire to obtain if possible. I think the better plan is to lengthen the tendon by the ordinary methods, which you all understand, of cutting into the tendon above at this point (illustrating), and cut down near the end, turn the piece around and do the same way below, bring the two parts together, and it requires only a few short sutures to hold them in place; at the same time you lengthen the tendon. Instead of building in a bridge of catgut you simply lengthen the tendon with its own substance, and the reparative process goes on satisfactorily. On the other hand, if you have to suture the tendon in order to bring it together, I prefer silkworm gut to catgut or silk, as the silkworm gut is stronger and less liable to become septic, and when put in position it remains unabsorbed for a long time. I have had very satisfactory results from its use. It seems to me with all of these different methods—any one of which you may adopt—it is highly important that you warn the patient against the possibilities of impairment of motion in cases of this kind. I recall a case I was called to treat a few months ago. In attempting to lift a barrel of salt, a railway employee tore the tendon of the long head of the biceps from its insertion. I made an incision in a line with the normal position of the tendon, beginning the incision just below the fibers of the deltoid and extending it downward some two inches. I found the muscle contracted, and the tendon coiled up with the belly of the muscle midway between the shoulder and the elbow. After fishing out the tendon I passed a strong double silkworm gut ligature through it, which I attached to a long needle. I carried this needle up the groove for the tendon under the deltoid and pectoralis major fibers to its normal point of insertion where I firmly anchored it subcutaneously. By this method I replaced the dislocated tendon besides anchoring it firmly at its normal point of attachment. By placing the arm in a Velpeau bandage the muscle was relaxed and the result was a speedy and very satisfactory recovery, with good use of the arm.

DR. R. S. HARNDEN, of Waverly, N. Y.—I desire to express my pleasure at hearing the remarks of Dr. Reed in regard to this subject. It seems to me important, simply from the fact that it has received so little attention, also because of its importance with regard to the prospective feature of damages to railway companies. Some ten or twelve years since I undertook to suture tendons and, while I think at that time we were usually advised against suturing them, I undertook to go against that advice. I sutured the tendon in a case to relieve the patient from deformity and I had the usual result, I suppose—a thecitis which alarmed me—and I proceeded to take out my suture and made up my mind that I would never use one again. I thought I had acted unwisely in going against what I supposed was authority in the matter. This subject was held in abeyance by me until the advent of aseptic treatment. Since that time I have used sutures in tendons with invariably good results, and I have become satisfied that the suturing of tendons is not only feasible, but proper, whether authority in the past has recommended it or not. The method of suturing tendons to overcome the natural shortening and contraction, as Dr. Sayre puts it, is something original. I would like to ask the Doctor if it is not a new method of suturing?

DR. REED—Yes, it is a comparatively new method.

DR. HARNDEN—It overcomes the natural method of shortening in a tendon. I would also emphasize the use of antiseptics and experimentation in this direction, because I think this subject may still become more important and useful to us.

DR. F. H. CALDWELL, of Sanford, Florida—I do not have a great deal of this work to do, but I have sutured some tendons, and have to report in a majority of cases that I have

given relief to the unfortunate ones. By releasing the tendon from its surrounding adhesions I have been enabled to render the limb fairly useful, after making a resection and by suturing. I have never tried the plan mentioned by Dr. Reed of lengthening the tendon.

DR. F. H. PECK of Clinton, N. Y.—In incised wounds of tendons it is a very simple thing to put in a buried suture, making an end-to-end approximation of the tendon and getting a very nice result. In the class of injuries we are called upon to treat as railway surgeons, we are liable to get a contused wound of the tendon which will cause sloughing of the bruised parts and consequent shortening and contraction, and it seems to me it is important that when the tendon is likely to slough we should excise the bruised ends and then make our lengthening of the proximal and distal fragments of the tendon by the method that Dr. Reed has already mentioned.

DR. L. E. LEMEN, of Denver, Colo.—I have tried the plan that has been mentioned, but in the last six or eight months, in addition to suturing after rendering the wound as aseptic as possible and removing the bruised tissues, I have been in the habit of dusting the tendon, before I sew up my incision, with stearate of zinc, thereby preventing adhesion of the tendon to its sheath. You will be surprised how nicely it works. The stearate of zinc will remain for quite a while. You apply it to the wound and then seal it over. It is simply to prevent mechanical adhesions of the tendon to the sheath.

DR. REED—Do you not have to make it aseptic in order to avoid sepsis?

DR. LEMEN—I render the wound antiseptic before I apply my suture and then wash it afterward. I do not use it as an antiseptic, but simply to prevent mechanical adhesions. It is one of the best powders for eczema or galling, or of any surface that is raw. I simply use my finger and rub it all around the sutured ends of the tendon until I varnish it over, so to speak, and sew the parts together. I have a great deal less trouble in having the tendon itself unite since practicing this plan.

DR. REED—I am not sufficiently familiar with the stearate of zinc to know whether it is antiseptic or not, or whether if we were to put in a wound, it will be the means of infecting the wound, or whether it would be necessary to submit it to any process by which it could be made aseptic. I heard a prominent surgeon advocate making antiseptics aseptic a few days since. Is this one of this kind?

DR. LEMEN—In cases in which I have used stearate of zinc, I will say that I have had union by first intention.

DR. C. M. DANIELS, of Buffalo—I think Dr. Reed and Dr. Lemen struck the keynote of this question when they referred to antiseptic treatment. Many years ago it was considered by leading surgeons almost criminal to perform subcutaneous tenotomy, but we have reached a point where we can incise tendons and suture them with a considerable degree of success.

DR. HARNDEN—I would suggest one point in regard to the prognosis that seems to me important, as we are working for the interest of science and admittedly for the interest of the companies we represent. Inasmuch as there is a prospective feature of damages always in sight, I believe it is admitted that in a resulting contracture from injury to the tendons there is the feature of damages. Now in the light that has been given us by Dr. Reed's description of this operation, which seems to be very valuable, can we not render the prognosis of cases of thecitis, or the result of an injury to the tendons where contracture has taken place, more favorable, thereby benefiting the company and science as well by this operation? I simply call attention to that point.

DR. JOHN E. OWENS of Chicago—I feel somewhat handicapped in discussing this subject, as I did not hear the paper. I may say, however, that the prognosis after operations upon tendons is most favorable, not only when done at early, but at remote periods, and particularly is it the case if you can bring the two ends of the tendon together, after having prepared them for suturing. I think that this can be done by certain well-formulated operations for splitting and splicing one part with a piece taken from the other. It can be done by stitching the end of the divided tendon to the contiguous tendon, all of which you can do well, and I think it ought to go without saying that the prognosis after such procedures must be favorable.

Take, for instance, the case which I have in hand at the present time. It seems so simple that I feel like apologizing for mentioning it. The wound occurred across the dorsum of the hand of a patient during my absence, and when I returned to the city it was noted that the patient could

not extend the middle finger. Two weeks afterward the ends of the tendons were readily united by making a longitudinal incision corresponding with the tendon, freshening the ends, bringing them together. The patient now has full control over the finger. If this case had been allowed to go on a considerable time without operation there certainly would have been added an element of cost which would have doubtless brought larger damages in case of a medico-legal contest. The time does not seem to cut a very important figure in the matter, because I have seen records of long periods after the accident where operations have been done for the purpose of uniting tendons to contiguous tendons for the purpose of restoring the loss of function. In the case referred to the question comes up when I ought to remove the splint. I am disposed to keep it there for six weeks, because on account of flexion I was afraid the new cicatrix might be gradually elongated and finally give way and the effect of the operation would be lost. I would say that rather long continuance of the splint seems to be essential.

DR. REED—Before the discussion is closed, there is one point that it might be well for us to remember, and that is when we make a tenotomy, we will say of the tendo-Achilles for shortening of some kind as the result of some accident or disease, we all know that union takes place subsequently. That is a fact which we should consider before treating a tendon by suturing. We all know that where the tendo-Achilles is an inch too short, by making a tenotomy there is an inch of space to be filled up. We understand that space is not filled up with tendon but with connective tissue that is built up during the reparative process by the proliferation of connective tissue cells and which unites the two ends of the tendon by this band of connective tissue. We must take into consideration that where we have a fracture of the tendon, where it is possible to immobilize the part and where shortening is not too great, we can depend upon the reparative process in cases of this kind. Under these circumstances, I would not advise making a compound wound of one that is simple when it can be repaired by nature in this way. In my former remarks I was speaking of the class of injuries of the tendon which could not be repaired in this manner. I think it is the proper thing to splice the tendon by the well-known methods of recent date, whether by suturing or otherwise, as the case may be.

The Committee on Constitution and By-Laws being ready to report on that part relative to the duties of the Editor, such report was made, and on motion of Dr. C. B. Parker, Cleveland, Ohio, adopted.

On motion of DR. R. HARVEY REED, Columbus, Ohio, the Constitution and By-Laws were then, as amended, adopted.

On motion of DR. C. K. COLE, Helena, Mont., the Secretary was instructed to have the Constitution and By-Laws printed and a copy sent to each Fellow of the Academy, together with a slip authorizing the Secretary to sign the Constitution and By-Laws for them.

On motion of DR. C. D. EVANS, Columbus, Neb., the Committee on Publication was authorized to secure certificates of fellowship.

On motion of DR. R. HARVEY REED, Dr. W. H. Elliott, Savannah, Ga., and Dr. L. E. Lemen, Denver, Colo., were appointed to conduct the newly elected President to the chair.

DR. COLE, in accepting the Presidency of the Academy, spoke as follows: Mr. President and Fellows of the Academy: I feel that it would be inopportune for me to attempt to make any extended remarks at this time. Because first, we have no time to devote to that sort of thing, and also, because I am totally unprepared to say what would seem befitting upon this occasion. I can do no more than to make my profound acknowledgments for the distinguished honor which you have voluntarily conferred upon me, and to say to you that I am not unmindful of the gravity of the duties which I shall assume in becoming the President of this organization. I desire to say further, that I pledge you in the interest of railway surgery that I will give my very best efforts in behalf of the institution which we have organized upon this occasion. In saying this, I am not saying any more than any gentleman has already said to himself, and whatever I may do, as well as the other officers of the Academy, will necessarily be entirely unavailing unless they are seconded by your efforts. While I think we all appreciate the fact that we have taken an important step, and one fraught with grave responsibilities and important possible results, I question whether we ourselves, notwithstanding the consideration we have given this matter, fully appreciate the step we have taken and the importance of this structure which we are about to rear. If the American Academy of Railway Surgeons fulfills its mission, we will have been factors in

making history in this country in connection with what is destined to be one of the most important branches of medicine—railway surgery.

Gentlemen, I trust you will excuse me and the embarrassment under which I labor. I feel keenly my inability to properly respond and give voice to the sentiments of my heart. I reiterate what I have previously said, that I will endeavor to the best of my ability to aid in advancing the objects and aims of this Academy and ask of you your indulgence and aid in furthering this plan. (Applause).

The following standing committees for the ensuing year were appointed by the President:

Committee of Arrangements: Chairman, Dr. A. D. Bevan, Chief Surgeon Iowa Central R'y, Chicago, Ill.; Dr. F. H. Caldwell, Chief Surgeon S. F. & W. R'y, Sanford, Fla.; Dr. J. H. Ford, Chief Surgeon, Big Four R'y, Wabash, Ind.

Committee on Transportation: Dr. W. J. Galbraith, Chief Surgeon, Union Pacific R'y, Omaha, Neb.; Dr. G. W. Hogeboom, Chief Surgeon, A. T. & S. F. R'y, Topeka, Kan.; Dr. A. C. Scott, Chief Surgeon, G. C. & S. F. R'y, Temple, Tex.

After short addresses by the different officers elected, the Academy adjourned to meet in Chicago on Sept. 12, 13 and 14, 1895.

### American Electro-Therapeutic Association.

*Fourth Annual Meeting held in New York Academy of Medicine, New York, Sept. 25, 26, and 27, 1894.*

WILLIAM J. HERDMAN, M.D., President.

(Continued from page 522.)

DR. G. BETTON MASSEY, of Philadelphia, read a paper on THE GALVANIC CURRENT IN CATARRHAL AFFECTIONS OF THE UTERUS.

The keynotes to the prevailing methods of treating pelvic disease may be said to be the following pathologic dicta: That the cause of the given complaint is either 1, a narrow or constricted os, producing menstrual obstruction; 2, a bend in the neck or body of the uterus resulting in the same conditions; 3, a mechanical displacement of the uterus causing congestion, enlargement and even inflammation; 4, a laceration of the cervix or even the scar tissue resulting from it, causing enlargement of the uterus, congestion, and a host of reflex symptoms through the agency of the nervous system; 5, a salpingitis, unassociated with other conditions; or 6, a diseased ovary or ovaries, similarly unconnected with more important concurrent conditions.

These six generalizations in pathology do not cover the whole field of pelvic diseases, but any one conversant with the every-day practice of the average gynecologist will agree with me that they represent the conceptions formed by him in the majority of his cases. Some of these conceptions are of recent origin; others date from Marion Sims and his earliest followers, and have molded practice for forty years.

It is noteworthy that but one of these conceptions, that of salpingitis, has any bearing on the modern facts of bacteriology, the accepted facts of endometritis being really neglected in practice. This neglect of the germ theory in the pathology of uterine disease is even more remarkable, when we consider the importance accorded the same theory in the operative precautions of surgical practice.

It is my own conviction that a catarrhal affection of the uterine cavity is at the bottom of many of the complaints heretofore referred to various mechanical deviations in and about the uterus; that it is far more frequently the cause of menorrhagia or menstrual pain than any alleged narrowing or bending of the cervical canal; that it is the prime cause of the enlargement that accompanies metritis, whether associated with laceration or not; and that it is the initial lesion in both salpingitis and oophoritis, often persisting after their appearance as a most important factor in the case. Its relative importance when associated with these conditions is attested by the fact that in many instances it remains to annoy the patient after the cervix has been torn apart in one class or sewed up in another, after the pessary has been worn for years, or the tubes and ovaries have been removed from the body. The day is past when we can consistently expect to cure a microbically-produced proliferation of the uterine endometrium and parenchyma by stretching the cervix, by stitching it up, or by merely propping up a heavy or displaced organ; and the day is equally far past when we should expect to cure the same condition of the uterus by removing ovaries and tubes that have become

affected by an upward extension of the process; yet at no time in medical history are these illogical procedures more frequently resorted to or more generally regarded as orthodox than at the present moment.

The opportunities afforded by the post-operative history of some of their cases has, however, had its effect on certain gynecologic surgeons who now announce their conviction that the uterus itself should be removed when operations are undertaken for diseased adnexa, and from all over the land come reports of the performance of complete amputations and extirpations of this nature. This acknowledgment of their previously neglectful attitude toward the uterine seat of the catarrhal process would be more encouraging if it were not accompanied by the hopelessly pessimistic prognosis that advises amputation rather than an attempt to cure. Lawson Tait is said to have graphically answered a questioner as to his treatment of chronic metritis by thrusting a red hot wire into the uterine cavity of a patient on the table; but these gentlemen prefer the knife and total destruction to even this heroic treatment.

The members of this Association are thoroughly conversant with the admirable results to be gained from the use of the galvanic current within the uterine cavity in this intractable affection, yet I fear that the allied work in the treatment of true fibroid processes has cast somewhat into the shade this important additional contribution of Apostoli to our practical resources. To the general profession, itself, this work is almost unknown; a fact due not only to the pathologic errors alluded to, but to a misconception of the range of the activities of milliampere currents. To many physicians electricity is nothing but a nerve and muscle stimulant—actions extremely valuable, it is true, in relaxation of the uterus, but far less important than the alterations of tissue activities by which absorption and trophic regeneration may be initiated. In these catarrhal hyperplasias of the uterus, electricity has a fourfold value, combining within itself probably four times the usefulness of any other remedial agency, for it is at once an antiseptic, a stimulant to absorption, a nutritive stimulant and a means of lessening uterine bulk by contracting the uterine muscular tissue.

For therapeutic purposes, these cases may be divided into two classes: those in which the uterus is movable by reason of the fact that the catarrhal process has not yet ascended into the Fallopian tubes; and those in which the uterus has become adherent or fixed by a metro-salpingitis or its consequences. The movable class is by far the more readily cured by electrical applications. Any appropriately curved electrode may be used within the cavity, skillfully inserted, for the application of the negative pole of the galvanic current, though my practice of late is to more frequently employ the positive pole, necessitating a platinum electrode. This latter polarity is imperative in hemorrhagic cases, and is distinctly best if any form of discharge is abundant. Another reason for the use of the positive pole is its distinctly microbicidal power in doses above 50 milliamperes, under the conditions of electrode surface existing in these applications. As to the question of the dosage used, however, I find that in my own practice it is more often below than above the figure mentioned, 35 or 40 milliamperes being often the limit.

In the second class of affections, those in which the uterus, while yet retaining the initial catarrhal affection and its hyperplastic consequences, is handicapped by an extension of the chronic process upward along the tubes, with more or less adhesion between the diseased structures and neighboring surfaces, the intra-uterine treatment must be extremely circumspect. It is best preceded by a course of a vaginal galvanic applications by means of moist, cotton-covered electrodes and strong currents, with possibly the addition of calomel faradic currents. The intra-uterine treatment by means of galvanic currents will nevertheless be necessary if we expect to do more than alleviate this unfortunate condition, and it is employed in its least painful form if the elastic platinum instrument is used, either bare as ordinarily employed, or covered with cotton if the cavity is patulous and sensitive. In cases where the extra-uterine morbid conditions are of long standing, curative results are possible, though we must often be satisfied with a more or less permanent amelioration of the symptoms. With the cases of uncomplicated catarrhal hypertrophy, on the other hand, the results should always be perfect, the morbid conditions yielding slowly but surely to the directly applied alterative agency. Not only may a resolution of the uterine process be thus gained, but the disappearance of swelling about the uterine end of the tubes will permit catarrhal accumulations within the

latter to be drained through the uterus, several well-attested instances having occurred within my own experience.

Appended to this paper will be found a tabulated analysis of thirty-four unselected cases of catarrhal disease of the uterus which have been more or less under galvanic treatment. The histories were consecutively extracted records of my private and hospital practice, and state the results attained, so far as known, together with clinical and therapeutic data.

Of these thirty-four cases, twenty-four were found to be of the movable class, of which seventeen were cured and seven improved. Ten cases belonged to the adherent variety, of which four were cured and six improved. Eight of these patients are recorded to have become pregnant after the cessation of the treatment, six having been of the movable variety and two of the adherent.

DR. L. A. W. ALLEMAN, of Brooklyn, N. Y., read a paper on  
ELECTRO-THERAPEUTICS OF DISEASES OF THE EYE.

It is not my purpose to enter into an exhaustive consideration of all the possibilities of electro-therapeutics in the

treatment of ocular disorders, but to invite you to discuss with me some of the more important and better established indications for its employment.

In ophthalmic surgery, as in all other branches of medicine, the charlatan has found "electricity" a fruitful field for his endeavors. "To vivify the decaying nerve, by the tamed lightning," has proved a very catching phrase and the discouraged patient receiving no promise of relief from legitimate medicine, has again and again caught at this straw only to be disappointed. I doubt not that these perennial electric humbugs have done much to discourage the profession from enthusiastically investigating, and sifting out the really beneficial, from among the much that was worthless or actually harmful that has been asserted for electro-therapeutics. Then, too, the class of cases in which electro-therapeutics is indicated are, as a rule, chronic, and it is impossible that this, or any other treatment, will yield immediate and startling results, and patient and practitioner are apt to become discouraged, and abandon treatment before sufficient time has elapsed to render an appreciable improvement possible.

I am, however, convinced, that used intelligently and perseveringly, we have in electro-therapeutics, an agent which in certain classes of ocular disorders is of the utmost utility, and one which will yield us results which can be obtained by any other method with difficulty if at all; and I am farther convinced that the scope of its applicability will be found to broaden in the light of farther experience.

There are already many conditions in which the indications are clear and the results immediate and definite. Such for example, as when an annoying irritation is kept up in the eye, by the presence of lashes which either through a faulty position or direction rub against the ball. When this condition extends to a part of the lid only, (partial trichiasis) electrolysis furnishes the best method of treatment at our command. For this procedure, no special apparatus is required beyond that necessary in ordinary office practice.

A battery of eight or ten cells, a milliamperemeter, an electrolysis needle (it is much preferable to use a stronger battery and a rheostat,) are all that is required.

Platinum needles are often employed for electrolysis; but a very fine steel needle is more serviceable in destroying cilia. I prefer a needle holder without a circuit breaker; it is sufficiently difficult to insert and hold a delicate needle in the hair follicle, without the unnecessary manipulation of working the circuit breaker with the fingers. The circuit can be closed by a floor button by an assistant, or by the patient, who presses the anode upon the skin when directed. The anode should be large and well moistened.

The patient should be placed in a reclining chair, with the head comfortably fixed on a rest, and in a good light. The whole success of the operation will depend upon reaching with the needles the bottom of the hair bulb which is to be destroyed, and if this is properly done there should never be any question of the permanency of the relief afforded; as these hairs are often set very obliquely. This is by no means an easy task and one has to learn by experience the sensation of resistance which is experienced when the needle leaves the follicle. The needle (the kathode) being well down past the bulb, the circuit is closed and a current of 3 or 4 milliamperes passed until a little froth is seen to bubble up about the needle. The hair is then withdrawn with an epilation forceps and should come away without the slightest resistance. If it is not thoroughly loosened, the operation should be repeated, several hairs should be removed at a sitting and the treatment followed up till the lid is entirely free.

The patient will experience some little pain during the passing of the current, which is not relieved by cocaine; which will, however, render the insertion of the needle practically painless; but so severe is the distress occasioned by the lashes that patients never rebel at a little pain, if it will insure them permanent relief.

*Herpes Zoster* is a condition in which galvanism has been found empirically of great utility. The distressing neuralgia is relieved by it, as well as the duration of the disease lessened. The direction of the current does not seem to be a matter of great importance, as good results have followed its use, however employed. The anode seems, however, to be preferable on the painful nerve and a current of  $1\frac{1}{2}$  to 2 milliamperes for ten minutes every day. I have in this way obtained excellent results in several cases.

*Conjunctivitis Granularis.*—Among the myriad remedies which have been advocated in the treatment of granular conjunctivitis, electrolysis has found a place and justly, as it is an agent of undoubted utility.

Whether there be any special indications for its use, I know not, save that it must be used in the stages preceding cicatricial contraction. In the use of electrolysis, as in any other treatment of this disease, the natural history must not be lost sight of. The goal to which the case is tending, and the termination which we wish to prevent is the final stage of cicatricial contraction and atrophy. For this reason, any method should be deprecated which involves tissue destruction. All severe applications and operations, although attended by temporary benefit must in the end be harmful, and a current which destroys the deeper conjunctival tissues is even more harmful than a knife.

George Lindsay Johnson has published<sup>1</sup> a very valuable paper on this subject; he points out that in many cases the indifferent success which attends treatment is due to the failure of the applied remedies to penetrate to the deeper layers of the conjunctiva, and suggests the use of electrolysis. His method is to make scarifications in the conjunctiva, and to follow the track of the scarifier with an

electrode. He reports excellent results. The only criticism on his work is that he uses a current of 30 milliamperes. I would not feel safe in using a current of anything like this strength in the conjunctiva, and it strikes me as odd that in the paper he deprecates the use of strong currents.

D. T. Myers, of Philadelphia, has also furnished a valuable contribution to the subject of electrolysis in granular conjunctivitis and his method is preferable, in that he uses no scarification and milder currents: he destroys the granulation with a needle, thus sterilizing each sac.

It will require much time and patience in practice, but I have found it to work admirably in the few cases in which I have tried it. The lid can be anesthetized by cocaine, and when necessary Myers uses the solid salt; he advises one and one-half to two milliamperes, which would be entirely free from objection. Many cases are amenable to treatment, by the ordinary methods; but we will now and then meet cases in practice, which are entirely unrelieved by the antiseptic and astringent applications or even expression, and for such I hope we have a new resource in electrolysis.

*Stricture of the Lachrymal Duct.*—In occlusion of the lachrymal punctum, and in strictures of the canal, the old treatment of slitting up the punctum and passing probes after dividing the stricture leaves much to be desired. The punctum loses its usefulness as a capillary canal after the operation, and we too often find that the operation which was at first eminently successful, fails to afford permanent relief. It is far preferable, when possible, to dilate the punctum and inject antiseptic solutions, and this procedure is greatly assisted by electrolysis. Several observers have reported favorably on this treatment, and the experiments of Lagrange<sup>2</sup> on the antiseptic action of electrolysis do much to explain its utility. The benefits are not, however, confined to the antiseptic action of the current. It undoubtedly tends to reduce the swelling and hypertrophy of the mucous membrane lining the duct, and the results of the treatment are fortunately much more permanent than by the use of probes alone. When the punctum is occluded, it can usually be sufficiently dilated by a conical probe, to admit a small lachrymal probe into the duct. This is made the kathode, and a mild current of say 2 milliamperes passed for three or four minutes; the probe which was at first tightly grasped will be now found to lie loosely in the canal, and a larger one can be introduced. If this is followed up, allowing an interval of a day between treatments, and the injections used at the same time, the treatment will be much less tedious and the results much more permanent.

Lagrange<sup>3</sup> while indorsing the use of electrolysis and reporting good results from it, gives, very wisely, a word of caution against the employment of very strong currents which would produce sloughing and subsequent cicatricial contraction. I have noticed an interesting fact in this connection, viz., that the passing of a probe, made by the kathode with a mild current is much less painful than without the current which is an additional reason for the use of electrolysis. One must remember not to use the anode, as much pain and reaction attends its use and the probe instead of passing easily is even more firmly grasped in the canal than before the current is applied.

*Keratitis.*—To relieve the blepharospasm, and the distressing photophobia, which does so much to make miserable the little sufferers with this disease, as well as to retard the cure, the constant current is a valuable adjunct to treatment. This is mentioned in Althus, and I have found it of much utility; a current of 2 or 3 milliamperes on the closed lids, anode to the eyes for five minutes at a sitting, is, I believe, the preferable method of employment.

*Corneal Opacities.*—The use directly upon the site of the opacity, with a corneal electrode and a current of from one-half to one and one-half milliamperes kathode to the eye is the best, and so far as I know, the only way in which old opacities of the cornea can be at all benefited; under the use of galvanism, in time, old and dense opacities can be thinned down and, if proper care is exercised, no distressing reaction need follow the application.

I have presented this subject in detail to this Association at a previous meeting,<sup>4</sup> and I will only add that my subsequent experience has tended to increase rather than diminish my confidence in the possibilities of the treatment.

*Retinitis.*—In certain forms of retinitis much can be accomplished by employment of the constant current. In retinitis diabetica, I have obtained most excellent results. Not only has the central scotoma when present, diminished

<sup>2</sup> Journal de Med. de Bordeaux, August, 1893.

<sup>3</sup> Eleventh International Medical Congress.

<sup>4</sup> The Times and Register, Nov. 21, 1891.

and the vision much improved, but the ophthalmoscopic picture has shown that the effect on the tone of the retinal vessels has been most pronounced. In one case in my practice, a few years since, I had an opportunity to demonstrate this very satisfactorily. The patient was suffering from retinal hemorrhage; small punctate hemorrhages were scattered in the greatest profusion in the fundus, and vision was seriously interfered with. I endeavored for some time to give the patient relief by rest, the correction of ametropia and the like; but the case failed to improve. I then began the use of the galvanic current, diet and medical treatment remaining unchanged. She steadily improved, the hemorrhages cleared up, and the vision showed a corresponding increase. After several months, she was so much better that treatment was discontinued. She remained very comfortable for a year or more, when she again had a recurrence of the hemorrhages and again under treatment made a gratifying recovery. In several subsequent cases, although not having so marked a result, I have been much gratified by the success attending the treatment. I used a current of one to one and one-half milliamperes through the closed eyelids, with frequent reversals.

*Retinitis Pigmentosa.*—Among all the diseases which we are called upon to treat, none are more utterly discouraging than retinitis pigmentosa. The subjects are, as a rule, young and the termination is pretty sure to be, sooner or later, hopeless blindness. In such a condition any faint prospect of relief or retardation would be most welcome; but we are as yet, practically helpless as far as any direct treatment is concerned.

It is surprising that since Dor, in 1873,<sup>5</sup> published reports of improvement obtained by the use of galvanism, we have had so little experience contributed to our meager fund of knowledge. Gunn<sup>6</sup> has reported a few cases as benefited, but the most trustworthy reports thus far at our command are those of Derby<sup>7</sup> and Standish.<sup>8</sup> These experienced observers made careful studies in several cases, observing all precaution against error, and report results which are wonderfully encouraging.

Dr. Derby also publishes a personal letter from Mr. Gunn (June, 1894) in which he writes: "I have followed only one case of those I then published and the improvement has been, or rather was when last seen, permanent."

Dr. Derby presented two cases of retinitis pigmentosa, on which the current had been applied three times a week for three months. The sittings were for five minutes, with six to eight Stöhrer cells. The electrodes were, as a rule, placed on the temples, but sometimes above and on the eye. The results were slight visual improvement and marked increase in the size of each visual field, as shown by the charts; he also mentioned a case treated by Dr. Standish, which Dr. Standish reported in detail at the next meeting of the society. It was of a woman 33 years of age, who had noticed a failure of vision for three years; this had increased very rapidly the three months previous to her first examination by Dr. Standish; her vision was at that time reduced to 12-40 in the right and 12-50 in the left. The night blindness was so great that she could no longer go safely alone on the street at night. The ophthalmoscope showed a number of characteristic star-shaped spots of pigment in the periphery of the fundus of each eye. The field of vision did not extend over 20 degrees in any meridian in either eye. The patient was placed under treatment by the galvanic current, and no other treatment was employed. The sittings were of five minutes' duration and were, as a rule, repeated every five days. The anode was placed on the closed lid; the kathode on the brow or temple; the current employed was not more than that given by four to six Stöhrer cells. The treatment was continued for fifteen months and the result was most surprising and gratifying. There was a constant improvement in vision up to the last three months, since which the vision has remained stationary. Upon one occasion, when the patient absented herself for a period of six weeks, after having been under treatment for four months, the vision and field were found to have fallen off slightly. At the end of the treatment the vision was improved from 12-40 to 12-30 in the right, and from 12-50 to 12-15 in the left; the field from 20 to 75 degrees right; 70 degrees left, horizontal diameters; 60 degrees right and 68 degrees left, vertical diameters. These measurements were made upon a perimeter, and the greatest care was exercised to make the different examinations under uniform conditions. The ophthalmoscopic

changes which took place while the patient was under observation were confined to a widening out of the prolongations of each patch of pigment, so that they did not present so characteristic a picture as when first seen. No new pigment patches appeared.

Such results as these should stimulate us to further investigation, and should they be confirmed by good results the effort will be richly repaid.

#### DISCUSSION.

DR. HOLFORD WALKER, of Toronto, said that Dr. Fuller, of Montreal, had been consulted by a physician's wife who six months previously had suffered from la grippe, followed by paralysis of the ciliary muscles. About two weeks ago she had come to him with the suggestion that he should do something for her with electricity. He would like to know what Dr. Alleman would do in such a case.

DR. ALLEMAN replied that the constant current frequently reversed was the most likely to give good results, but the outcome in such cases was very doubtful, some of them recovering very suddenly without treatment, and others proving obstinate under what appeared to be well directed measures.

DR. BEAVER, of Reading, Pa., said he was very much pleased with the success the author had had with electricity in the treatment of so many diseased conditions of the eye. He wished, however, to criticise the paper in one particular, *i. e.*, the importance of considering the element of time. It had seemed to him that most of the papers already presented were lacking in this same particular. In this last paper we had not been told how often the applications were made, how long they had been continued, or the amount of pain produced by them. Just as we need to be precise in stating the doses of drugs, so should we be particular in stating the exact conditions under which we employ electrical treatment. He had never found it necessary to use the very strong currents which had been recommended, either in the treatment of eye diseases or of gynecologic cases.

DR. O. S. PHILIPS, of New York City—referred to an interesting case, that of a lady who had been operated upon about one year ago for cataract. From partial blindness in one eye and perhaps half vision in the other, there was total blindness after the operation. The lens was broken up and the cavity filled with opaque matter. He would like to ask the reader of the paper whether he had had any experience with galvanism directed toward causing absorption of any such deposit?

DR. ALLEMAN said he had tried galvanism only in incipient stages of cataract. In the case reported he thought it would accomplish no purpose. As to the remarks of Dr. Beaver, he would say that he was entirely in accord with him regarding the importance of accurately stating the dosage and time of application, and he thought he had done so in most of the instances mentioned in the paper.

DR. CLEAVES said that she thought optic atrophy had not been mentioned by the author. It might be interesting therefore to report such a case, which had been under her care during the last six months. The atrophy was of four years' standing. R. V. was found to be 1-200 with a correction of one dioptre, and L. V. 1-200. The patient could read No. 12 of Jaeger's type. For the first two weeks he received three applications daily of the constant current with from 1 to 5 milliamperes, depending upon the tolerance, which varied from day to day. The indifferent electrode which presented an area of eighteen square inches, was placed at the nape of the neck, and the active electrode over the eye. The method was by changing the polarity. Always following the voltaic alternations a mild application of the sinusoidal current was made, with position of electrodes unchanged. During the months of August and September the treatments were not regular. On Sept. 22, 1894, the patient was re-examined by Dr. Francis Valk, who reported that there was a decided improvement in the distant vision, R. V. being 10-200, with a correction of two dioptres = 10-100, and L. V. 20-200 with correction of 1-36 = 20-50. The vision in the left eye had improved about 100 per cent., but otherwise in the examination of the field the appearance of the fundus of the eye was about the same. Symptomatically, the patient was in much better condition. He could now read letters, and could see objects clearly in going about the room and street, which he could not do before the treatment.

The Association then adjourned at 6 p.m.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, APRIL 13, 1895.

THE STATUE OF PROFESSOR GROSS.

"For if our grief is alleviated by gazing on the pictures of departed friends in our houses, how much more pleasure is there in looking on those public representations of them, which are memorials not only of their air and countenance, but of the honor and esteem with which they were regarded by their fellow-citizens."—PLINIUS EPISTOLÆ.

The day before the adjournment of Congress, that body passed the following public resolution:

[PUBLIC RESOLUTION—No. 21.]

Joint resolution granting permission for the erection of a bronze statue in Washington, District of Columbia, in honor of the late Prof. Samuel D. Gross, Doctor of Medicine, Doctor of Laws, Doctor of Civil Law.

WHEREAS, The physicians and surgeons of the United States of America have raised a fund for the erection of a bronze statue to the memory of Samuel D. Gross, Doctor of Medicine, Doctor of Laws, Doctor of Civil Law, late Professor of Surgery in the Jefferson Medical College of Philadelphia, whose labors in the cause of his profession as surgeon and as author have caused his name to be respected in the civilized world as one of the benefactors of his race, and have added luster to the entire medical profession of the United States; therefore, be it

*Resolved by the Senate and House of Representatives of the United States of America in Congress assembled,* That permission be, and the same is hereby granted to the American Surgical Association and the Alumni Association of the Jefferson Medical College to erect said statue in such place in the city of Washington, District of Columbia, as shall be designated by the Superintendent of Public Buildings and Grounds. And the sum of fifteen hundred dollars, or so much thereof as may be necessary, is hereby appropriated, out of any money in the Treasury not otherwise appropriated, for the erection of a pedestal upon which to place the said statue.

Approved, March 2, 1895.

Great credit is due Drs. W. W. KEEN, of Philadelphia, and C. H. MASTIN, of Mobile, for their successful work in securing this public honor for the late PROFESSOR GROSS who as President of the AMERICAN MEDICAL ASSOCIATION and founder of the American Surgical Association, did so much for the elevation of the standard of American Medicine. Mr. Adams from the Committee on the Library, in reporting the bill gave an exhaustive and appreciative review of his life, literary work and services, and concluded as follows:

"The record of such a well-spent life is a valuable lesson, and in the opinion of the committee the erection of a statue to such a distinguished man in civil life will serve as an object of inspiration to the generations to come, as a monument of one of the brightest examples of skill, learning, patient study, dignity and morality that ever adorned the medical profession of our country."

It is well that this statue is to be erected while the generation that knew him in the ripeness of age is still alive, for experience warns us that the duty of commemorating virtue and learning as exemplified in any person, is neglected in exact proportion to the march of time.

SIR WM. TURNER DECLINES.

PRESIDENT DONALD MACLEAN, on behalf of the AMERICAN MEDICAL ASSOCIATION, extended an invitation to SIR WM. TURNER, of Edinburgh, to attend the Baltimore meeting. SIR WILLIAM would have been a welcome guest, for he is recognized in America as in Great Britain, as the greatest living anatomic philosopher. His article on "Anatomy" in the Encyclopædia Britannica, deserves to rank among the English classics.

In a pleasant response to DR. MACLEAN's letter of invitation, the venerable anatomist says in part:

"When your letter of February 28 reached me, I was ill in bed with a sharp attack of influenza, and

for some days after its arrival I was quite unable to give it the consideration which was due to it. Nothing could surpass the graciousness and cordiality of your invitation, and it did me good in my illness to think that my professional colleagues in America had been so kind and so considerate.

"In many respects I have felt that I ought to accept the invitation of the AMERICAN MEDICAL ASSOCIATION, and to take a part in its proceedings. There are powerful reasons to lead me to do so; the desire to meet distinguished members of my profession in America, the opportunity of seeing under such favorable auspices the beautiful city of Baltimore, and such other of your great cities as time would permit, and to visit your great educational institutions, such as the Johns Hopkins University and its distinguished President, whom I claim as a personal friend; were strong arguments in favor of my accepting this most cordial invitation."

SIR WILLIAM adds, however, that the debility following the grip compels him to decline to attend the meeting.

PRESIDENT MACLEAN, in giving the foregoing information to the JOURNAL, expresses what we are sure will be the voice of the ASSOCIATION—sincere regret, not only that the invitation was declined, but on account of the illness which occasioned the declination.

#### THE STATE SOCIETY VS. THE TRI-STATE.

Under our form of government, the States have the power that regulates manufactures, and the internal affairs of the State. Neither municipal nor Federal authority may meddle with that exclusive jurisdiction.

As Legislatures thus have almost supreme control over the citizens of the State, it naturally follows that all legislation which affects the profession and the direct sanitary interests of the people, must emanate from the State Legislature, and this necessitates similar organization on our part. If the medical profession are to influence a Legislature, it must be done by the State medical organization; no "Tri-State" organization can accomplish anything in the State except at the expense of the different State societies, and even then they can not take the place of the State society. The more the question is studied, the more clear will stand forth the principle that if our profession desires power, influence and consideration, every member of that profession owes it to himself and as well to his colleagues, that he support and maintain his local, State and National medical societies. These societies should be as a holy trinity to the medical man, and the necessary support should be given as a matter of duty.

These three societies surely afford an ample field for all the power, energy and ability that any medical man may possess, and in so far as the "Tri-State" societies weaken the respective State societies, they are directly harmful to the profession by loosening the ties of professional organization.

#### A FATAL RESULT FOLLOWING A HYPODERMIC INJECTION, BEHRING'S ANTITOXIN BEING THE INJECTED REMEDY.

A death has been reported at Brooklyn following a treatment of diphtheria by means of BEHRING'S antitoxin. The death is stated as having followed the injection in about ten minutes. This lamentable result occurred in the case of a girl in her seventeenth year, in the practice of a regularly equipped physician who had already had some very satisfactory experience in the use of the serum. The case was duly referred to the coroner of the county and an autopsy performed by a competent pathologist. The coroner's findings were inconclusive as to the true cause of the fatal issue of the case. The serum was all used upon the case, but other packages belonging to the same shipment from the same German laboratory were procured and tested.

There was nothing found in this procedure that can justly be held to inculcate the antitoxin used in the case. Experiments were made by the bacteriologists of the Boards of Health of New York City as well as Brooklyn, and these concur in tending to show that the serum was of sound quality, and in leaving the inference to be drawn that the hypodermic operation itself was at fault. Untoward accidents are not unknown as following that operation, and they are nearly always difficult of explanation except in a general way.

The accident, in this particular case, judging from the great rapidity with which the disaster followed the injection was doubtless a lesion of some part of the circulatory apparatus, although it must be admitted as possible that the bottle of antitoxin was not correctly labeled and really contained some toxin or other substance intended only for laboratory uses. Very little knowledge has yet been obtained regarding possible toxic alterations that may take place in the serum after bottling.

The following is taken from the report of DR. E. H. WILSON, of the Brooklyn Board of Health, and shows the line of experimentation followed by him to ascertain the qualities of the serum, of the same shipment as that used in the fatal case. He says, in effect: "I procured two bottles of BEHRING'S antitoxin No. 2, containing one thousand immunity units, sealed under the date January 30, operation No. 159, being a portion of the same lot as used in the case of BERTHA VALENTINE. Of this serum, 1 cubic centimeter was injected beneath the skin of a guinea pig weighing 420 grams; at 4:30 P.M. the animal suffered no inconvenience from this injection. At the same time 2½ cubic centimeters of the same serum were injected directly into the ear vein of a large rabbit; this animal also suffered no inconvenience. I also obtained from DR. CLAYLAND, coroner's physician, about one ounce of fluid blood received in a sterilized

bottle from the right auricle of the heart. One-half of this blood was given to the chemist of the department for chemic analysis. Direct microscopic examination and cultures made from this blood showed it to be free from microorganisms. Speculative theories may be advanced as to the cause of death in this case, the true cause not having yet been determined, but the above experiments conforming as nearly as possible to the actual condition, demonstrate that the cause was not inherent in the antitoxin."

DR. W. H. PARK, of the New York Board, also experimented with two vials of the same importation of "operation No. 159," and his report states: "I have submitted both vials to thorough tests at the bacteriologic laboratory of the Board of Health, by injecting excessive doses into guinea pigs and rabbits without producing in the animals any deleterious effects whatever. Specimens from both vials were also submitted to bacteriologic tests and were found to be absolutely free from living germs of any kind.

"These results, taken together with the fact that the New York City Board of Health has employed this same make of antitoxin in a considerable number of cases with only the best of results, leads me to express the opinion that the unfortunate results which followed its administration in the case referred to can not be attributed in any way to the antitoxin which was employed."

There have already been many hundreds, if not thousands, of injections made in this country of the imported serum, and this is the first accident of the nature described that has been publicly reported. On the other side of the ocean the number of serum treatments has been vastly greater, with only a very small proportion of untoward results referable to the remedy and not to the operation.

#### BUFFALO MEDICAL AND SURGICAL JOURNAL.

After a half century of good work in the cause of medical literature, and for the welfare of mankind, the *Buffalo Medical and Surgical Journal* proposes to signalize its semi-centennial anniversary by increasing its reading pages from sixty-four to eighty, and by making other improvements.

The editors will please accept the congratulations of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, on the youthful vigor which still characterizes our Buffalo contemporary despite the fifty winters that have passed away since it was founded. We hope that our contemporary may still be young and as active, when it celebrates its centenary.

#### PROGRAMS OF THE SECTIONS.

In order to prevent delay in the preparation of the program, Section officers are earnestly requested to send their *manuscript at once to this office*.

#### AFTER THE FIRE.

WE print herewith an illustration showing the appearance of the hallway at the entrance to the office of the JOURNAL, from which the members of the ASSOCIATION will see our narrow escape from a disastrous conflagration. It is a source of gratification that the Saturday issue of the JOURNAL was not only on time, but had the standard number of twenty-eight pages of reading matter. This is the smallest number issued since July, 1893, but it is the same size as most of the other weekly journals in the United States and the size adopted for the four years previous to 1893.

The hallway entrance to the JOURNAL office, after the fire.  
[From a photograph.]

We can not commend too highly the prompt and efficient service of the Fire Insurance Patrol of Chicago. Every night since the fire, while the roof has been open and exposed to the rain, the Patrol has promptly appeared and covered up every article in the office with waterproof tarpaulin. To this care and vigilance may be ascribed a large part of the saving that was effected.

Do not forget the JOURNAL SPECIAL TRAIN leaving Chicago Sunday, May 5, from Pennsylvania depot, 3:15 P.M. Write for space desired.

Blank Applications for membership in the Association, at the JOURNAL office.

## CORRESPONDENCE.

## The Case Against the Code.

SAN JOSE, CAL., April 3, 1895.

To the Editor:—I have just received a copy of a circular issued by the Philadelphia County Medical Society under date of March 11, 1895, desiring action by our county and State societies in relation to the character of advertisements that shall appear in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. This circular states among other things the following:

1. "The Code of Ethics—the moral and organic law of the AMERICAN MEDICAL ASSOCIATION—as is well known, not only prohibits physicians from employing secret nostrums, but declares that 'in any way to promote the use of such nostrums is reprehensible.'

2. "The advertising of such nostrums in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, which is taking place, is certainly an attempt to promote their use. The ASSOCIATION appears, therefore, at least tacitly to permit the Editor and Trustees of its official JOURNAL to transgress, in the conduct of the JOURNAL, the law laid down for our guidance as physicians."

It may be recollected that the present writer had something to say a year ago and more, in the JOURNAL, on the question of the revision of the Code of Ethics. I pointed out then some of the glaring inconsistencies as between some of the declarations of the Code and the practices of most members of the profession. I urged the importance of revising the Code that our professions and practice might be in harmony. But the majority at the San Francisco meeting thought that the old creeds had better stand, while we would go on belying them every day.

This Philadelphia County Medical Society assumes an air of immaculateness, innocence and virtue that is refreshing in these days of moral degeneracy and humbuggery. They say the JOURNAL OF THE ASSOCIATION must be immaculate like themselves, and stand on the very orthodox letter of the Code! There must not be the least shadow of a doubt about every medicine and thing advertised in the JOURNAL as being warranted by "The Patent Regulator," the Code. Their chief refrain seems to be in relation to proprietary medicines, forgetting at the same time that the Code also declares that no member of the ASSOCIATION shall patent a surgical instrument or appliance, and inferentially "that he must not use a patented instrument or encourage the use of the same." "Consistency, thou art a rare jewel!" What about the patent vibrometers, nebulizers, uterine supporters, artificial limbs, surgical chairs, and multitudinous other instruments advertised in the columns of the JOURNAL from time to time? Should the JOURNAL aid the use of patented instruments any more than proprietary medicines? Philadelphia County Society, stand up and answer!

The Philadelphia County Society may be composed entirely of members who are nothing but the true blue, Code of Ethics type of medical gentlemen; but if we can judge of that society by what we know of others, and at such long range, I would seriously question whether their practice corresponds with their preaching. In the first place, how many members of that society use proprietary medicines constantly in their practice? Yea, how many, even, have used antikamnia? How many members of that code-bound society use patented surgical instruments or appliances in their practice? Is it a sin to patent a surgical instrument, but not a sin to use one? Would the members of this society allow a patient to die before they would use a patented surgical instrument, and thus violate the Code? If not, why not?

This society says that a certain class of advertisements that are admitted to the columns of other supposedly respectable medical journals must not be published in the columns of our JOURNAL, as being inconsistent, and contradictory to the Code.

Let us put these gentlemen on the witness stand again: Do the members of the Philadelphia County Medical Society take any other journals than the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION? If so, do not all these journals contain in their advertising columns just the very class of advertisements that they declare shall not be published in our JOURNAL? Why do they take journals which aid and abet the use of secret nostrums or proprietary medicines? In doing so, are they not likewise aiding the use of said remedies?

As I said, in the first place: "Consistency is a rare jewel." If we are guided by an injunction which is much older than the Code of Ethics of our ASSOCIATION, and which reads, "Let him that is without guilt cast the first stone," I wonder how many stones will be thrown? I wonder if the members of the Philadelphia County Medical Society would make the air fairly black with missiles? Our own Augean stables must be cleaned before we insist on a general cleaning up all round. We must "get the beam out of our own eyes."

The only way to have consistency between the Code and the practice of the profession, in regard to patent things in general, is to remove the clause referring to the same from the Code. We know that we are professing one thing and practicing another now; why should the inconsistency continue?

Yours truly,

A. C. SIMONTON, M.D.

## Of What Use Is the Pharmacopœia?

FORT WAYNE, IND.

To the Editor:—I do not wish to disparage the United States Pharmacopœia in the least, nor to detract from the great merit of a work involving so much conscientious care and science and labor on the part of its authors, but I think I voice the feeling of the profession generally when I ask the question written above.

In England, the College of Physicians has a legal right to inspect apothecaries' shops, and therefore to determine to some extent the nature of their contents. In Germany, Italy, and some other European countries the civil authorities have control over pharmacies, and can fine the proprietors if a specified list of drugs of a specified quality be not kept in stock. But in the United States there is no legal control of pharmacy, except in regard to pharmacists' qualifications, and there is no pretense on the part of physicians to regulate the range of their remedies by the Pharmacopœia. A few druggists are still found who make their salts and tinctures as this authority prescribes; for most drugs and preparations are purchased from reputable wholesale dealers, and from manufacturers whose pharmaceutical laboratories are on a scale calculated to inspire confidence in the purchaser regarding the purity and standard strength of drugs sold. Hosts of small makers, too, compete for the patronage of the physicians, with a pill or tablet or elixir; and the German color makers supply most of the newer and rarer chemicals.

Under these circumstances, the Pharmacopœia seems to be out of gear with the times, and is to be looked on as a kind of survival from the past, like the great auk and the woolly rhinoceros. Yet it is quite possible that there is still a place for a United States Pharmacopœia, provided that the book can be made to suit the conditions of these days. Until then, it is only an expensive luxury, and an unnecessary imitation of works that—under the different laws of European countries—may have some good right of

existence. What number of American physicians use the Pharmacopœia in their practice, or have it in their libraries? What drugstore confines itself to the Pharmacopœia, or cares for it as an authority? What medical college uses the Pharmacopœia as a text-book for teaching materia medica? It was said once that the work "has got away from the medical profession;" but I think it is the profession—including pharmacy—that has emancipated itself from the Pharmacopœia.

In America, our chief use of such a work would be to fix or standardize the nomenclature of drugs. A second use would be to offer a list of drugs that are therapeutically efficient, distinguished from drugs that are valueless or inert, and from new remedies that have not been sufficiently tested. A third use would be to reinforce the decimal system of weights and measures in medical usage; and, to accomplish this, a new weight, the decimilligramme, should be added, and the system must be made to conform better to the *teaspoonful*, until the domestic and convenient measure can be eliminated.

More regard must be paid to the convenience of prescribers; the confusion between waters, liquors, and solutions, syrups, elixirs and glyceroles, tinctures, wines and spirits, and so on, should be abolished. A more extensive list of remedies, with posologic and therapeutic tables might be added. The list of preparations should be as brief as possible—especially of compound mixtures and syrups, and powdered extracts, tablets and troches should be recognized. We should regret to give up the Pharmacopœia; we should be glad to see it radically recast; but, in its present form, we are justified in asking, Of what use is the U. S. Pharmacopœia? W. P. WHERY, M.D.

### Leprosy Case—Where It should be Reported.

NEW YORK, March 31, 1895.

To the Editor:—I beg to state, with reference to one of your remarks in the Public Health columns, of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, March 30, as to my not reporting a certain case of leprosy directly to the local Board of Health that I take, in such affairs, a higher ground. According to my opinion, such cases should be reported to a United States Health Officer, and the State or City Board of Health should have nothing to do with them. The State Board of Health would think only of the protection of its own citizens, and would most probably do everything possible to shift the responsibility, that is the expense of the maintenance of the leprosy family on some relations or friends of the leper, living perhaps in another State. If the danger was averted from their own vicinity, their particularistic conscience would be perfectly satisfied.

A city board would rather shut its eyes and ears to the proclamation or avowal of existing leper cases, than to undergo all the evils resulting from the reception of such a communication. Think of the New York Chinese lepers who had to be shipped back and forth, to and from Vancouver, in box cars (like cattle), and then to be exposed miserably on the extremity of North Brothers Island, until death separated them still more from human charity, as they had been separated from it before. These things must be trying for any human being whose power and authority decrees them, and we have no reason to believe that the members of our Board of Health have harder hearts than the rest of us.

If these cases were reported to the United States Public Service, the Federal Government would have to protect every State equally, and the United States ships could return the lepers to the place where they came from, without those vain and expensive endeavors to get rid of them by way of Van-

couver, whence, as the British steamers declined to receive them, they had to be brought back.

I may add here, that I mentioned this beginning of a leprosy condition after the puncture of a fish-bone, to Professor Putnam. He said that while he was helping Agassiz in his investigations on fish, the assistants very often received poisonous wounds, but that these poisonous wounds were always painful. It must be remembered that the wounded place in our leper was anesthetic. Professor Putnam is of opinion that the poisonous element in fish resides in the mucus; for when the bones had been washed with alcohol, or simply dried, no puncture had any poisonous effect.

I must say that it seems to me quite probable that the leper whom I have seen here, had already when he came in contact with that fish, at least the beginning of leprosy anesthesia.

Dr. Bristow, of Brooklyn, asked me how I could explain the fact that in my case the tuberculation appeared first on the face, while the inoculation had begun in the finger. I answered that the tuberculation occurring in the face and outer sides of the forearms, and on the back of fingers is supposed by Unna to be due to selection by the bacilli; they established themselves in those regions where the least motion is felt. The occurrence of tuberculation in the exposed parts of the body is the strongest argument for the theory of host-inoculation. Yours truly,

ALBERT S. ASHMEAD, M.D.

### The Warren Formula.

ROSLINDALE, MASS., March 29, 1895.

To the Editor:—Will you kindly give me the name of the writer of the answer to "Injections in Hernia," printed on page 418, March 16 issue of the JOURNAL? I want to learn the page in Heaton on the "Cure of Rupture" where that formula occurs. As a fact the formula is copied from page 65 of "A Plea for the Cure of Rupture," by Jos. H. Warren, A.M., M.D., LL.D. You will find other formulæ on page 57. Heaton used only oak bark, pure and simple. The formula that you print was first used by my father, Dr. Warren, and was an improvement on Heaton's crude method. Heaton's book was published in 1877. My father's books were dated 1880 and 1884, and were considered authoritative.

I fail to see how such a flagrant mis-statement as crediting the formula to Heaton could possibly have occurred, and I trust a correction will be made at an early date.

Yours respectfully, CHAS. EVERETT WARREN, M.D.

ANSWER.—The prescription mentioned was quoted from Marcy ("The Anatomy and Surgical Treatment of Hernia," New York, 1892, p. 275). He says: "Dr. Warren began operating upon hernia by the Heaton method soon after the author's death. He stated in a note to his second edition, that he is 'convinced the credit of the origination of the method belongs to Dr. Pancoast; that to Dr. Heaton is due the discovery of the exceptional value of the thick extract of the oak bark.' . . . He greatly modified and improved the instruments to be used, both needles and syringe, and changed somewhat the medicamenta employed. Among the recipes commended the following is preferred"—Then follows the prescription given in our issue of March 16, 1895. It is due to Warren to say that Heaton used the fluid extract of white oak bark alone. The alcohol, ether, morphia and tincture veratri viridis were added by Warren. In our answer to our Alabama correspondent we gave the formula without the slightest intention to detract from whatever of merit was contained in the additions mentioned, or the twisted needle of the Warren syringe. Only a part of the editor's library is in Chicago, and in the transfer of a working collection, both Heaton's book by Davenport, and Warren's book were left in his Washington library.

### Diphtheria Epidemic at Akron—Use of Antitoxin.

CLEVELAND, OHIO, April 1, 1895.

To the Editor:—Permit me to submit for the columns of Public Health in the JOURNAL the following item:

An outbreak of diphtheria has recently occurred in the Summit County Children's Home at Akron, Ohio. Dr. L. S. Ebricht, physician in charge of the Home, and Health Officer of Akron, diagnosed and isolated the first case March 21. This boy recovered after a severe illness of a week's duration. March 27 another boy was taken sick, and the next day the disease appeared in three girls. The Home contains sixty children varying in age from 2 years to 15 years, and fifteen attendants. March 30, after making a preliminary bacteriologic examination of one of the cases, I went to the Home with Dr. Ebricht and administered the antitoxin obtained from our (Wooster Medical College) diphtheria-immune horse. The boy who had been sick three days was dying of a profound toxemia, and lived but six hours after my visit. Therapeutic injections of antitoxin were given to the three sick girls at my first visit, also to a new case brought into the hospital March 31. Aside from these therapeutic injections, immunizing injections of the antitoxin were given to all the children and all the attendants in the Home (seventy in all).

Bacteriologic examinations showed diphtheria bacilli in all of the sick children. The four patients who received the therapeutic doses are doing splendidly. Fever and pulse much reduced and *membrane all gone* in all these cases forty-eight hours after the first injection. No new cases have developed in the last two days among the immunized individuals. Thus far we have been unable to trace the cause of this outbreak, which is entirely confined to the inmates of this institution. There seems but little doubt that the prompt and liberal use of antitoxin has saved the Home from a devastating epidemic of diphtheria. Very truly yours,

A. P. OEHLMACHER, M.D.

### No Smallpox at Little Rock.

LITTLE ROCK, ARK., April 1, 1895.

To the Editor:—In the issue of the JOURNAL for March 23, page 454, under the heading "Health Reports," it is stated that from February 1 to March 8, eighty-two cases of smallpox and fourteen deaths have occurred at Little Rock! The report was sent out from the latter place and the error doubtless occurred from that fact, while Hot Springs is the place where the disease has existed and the figures refer thereto. There is no smallpox in Little Rock, but we have the Legislature. Very respectfully, L. P. GIBSON, M.D.

### Cold in the Treatment of Pneumonia.

1829 SPRUCE STREET, PHILADELPHIA, PA.

To the Members of the Medical Profession:—My last paper on "Ice-cold Applications in Acute Pneumonia" gives a record of seventy-four cases so treated, and only two deaths.

Being desirous of making a full collective report on this subject, I take the liberty of asking those who have tried this measure to kindly give me the result of their experience with it. Full credit will be given to each correspondent in the report which I hope to publish.

THOMAS J. MAYS, M.D.

### Infantile Scorbatus.

BOSTON, MASS., March 11, 1895.

To the Editor:—In a recent number of your JOURNAL there is a report of a case of infantile scorbatus in which the infant was nursed until three months old, then fed on Condensed Milk and Mellin's Food, upon which she seemed to thrive till she was about a year old, when certain pathologic symptoms were observed. One of the five doctors under whose observation she now passed, made an attempt to change her diet to cow's milk, but its use was abandoned as it caused nausea and constipation. When sixteen months old she was first seen in consultation by the writer of the article, and the diagnosis of infantile scorbatus was made; at this time the diet was changed by him to fresh cow's milk, with no record of digestive trouble.

He says: "The child was put on fresh milk and a rational diet suited to her age. The attending physician gave a little lime water and cod-liver oil for the rachitis. Later, when she came under my immediate care, Thompson's Solution was given for the same purpose. She steadily improved, and would now make a splendid picture for an advertisement setting forth the fact that proprietary foods are always useless and frequently dangerous."

The sweeping statement in the last sentence of the above quotation is not borne out by the record of the case. The writer says earlier in the article that "proprietary foods mixed with water or condensed milk are the most common causes of this disease. Condensed milk alone and fresh milk unduly diluted have also produced some cases." He superseded the Condensed Milk and Mellin's Food with fresh cow's milk; but he entirely ignores, in his summary, the effect of the Condensed Milk, which elsewhere in his article he says will cause scorbatus, and casts the blame wholly on the proprietary (Mellin's) Food, which he nowhere shows to have been the cause of it. It should be further observed that the Condensed Milk, of itself an inadequate food, was "unduly diluted," half a fluid ounce being mixed with eight fluid ounces of water. This half a fluid ounce of Condensed Milk must represent but a small amount of milk, and probably not the total constituents of that small amount. Condensed Milk being usually deficient in fat, and moreover Condensed Milk is not fresh milk.

It was not the Mellin's Food, it was the lack of fresh milk that caused the disease.

We quote from those eminent authors, Dr. Cheadle and Dr. Barlow, to prove that Mellin's Food was not the cause; these authorities the writer of the article also has quoted.

Dr. Cheadle states his conclusions in reference to infantile scorbatus as follows, in his work entitled "Artificial Feeding and Food Disorders of Infants," third edition, page 216: "In no instance have I seen the disease arise in an infant at the breast, or when fed on an ample supply of good cow's milk. Oatmeal and water, bread and water, various patent farinaceous and desiccated foods, peptonized condensed milk, sterilized milk, pancreatized farinaceous food and milk, German sausage, bread and butter and tea, beef tea, gravy and bread, in most cases with no fresh milk at all, in a few with a very small amount only, are the dietaries on which I have seen scurvy develop, and, latterly, most often on the peptonized and pancreatized foods now so much in vogue."

Dr. Barlow, in the Bradshaw Lecture on Infantile Scurvy (the London Lancet, Nov 10, 1894), says: "Let us turn to the question of food. In the group which I have described, in no single case at the time of onset of the malady has the child been breast-fed. In the great majority, where complete details have been obtained, these infants are found to have been nourished on what may be called 'preserved foods.' In the front rank come the various proprietary infant foods, prepared by the addition of water to certain powders. Then come the different forms of condensed milk, and the proprietary goods made with condensed milk. Then come cases in which, either accompanied by proprietary food or not, fresh milk has been given, but with extreme dilution, during the later stages of infancy."

These quotations from these eminent authors fully sustain our position.

The Liebig formula is a formula for the extemporaneous modification of fresh cow's milk; Liebig utterly condemned the use of farinaceous foods and Condensed Milk. Mellin's Food, a true Liebig food is not a dried milk food; it is not a patent farinaceous or desiccated food; it is not a peptonized or Condensed Milk; it is not pancreatized; it is a preparation for the modification of fresh cow's milk. Our advertisement which has been running in your JOURNAL and other medical journals for some time, brings this prominently to notice. We have been compelled thus to emphasize this point on account of the great efforts that have been made to promote the use of Condensed Milk as an infant food. And we assert, and our assertion is borne out by facts, that infantile scorbatus, "even now comparatively rare," has only been observed to any degree where condensed and desiccated milk and milk foods and other forms of devitalized milk have been substituted for fresh cow's milk. The directions require the use of fresh cow's milk with Mellin's Food; only as a temporary expedient in case fresh cow's milk is not obtainable should the use of Condensed Milk ever be permitted.

In further confirmation of our position we quote from the report of a case of infantile scorbatus, by Prof. William C. Hollopeter in the Medical Bulletin, of Philadelphia: "The duration of the disease was one year, and this long period was consumed by reason of the irritable condition of the gastro-intestinal tract. The slightest change in the diet would provoke a sharp attack of diarrhea. I placed the child on freshly filtered milk, cream, and boiled water, equal parts, which she failed to digest. I then began with freshly peptonized milk, which did well for a short time. Finally I was compelled to resort to equal parts of filtered milk, cream and boiled water, with the addition of two teaspoonfuls of Mellin's Food to each bottle. This seemed to meet the necessities of the case exactly. Meat juice, 5j (4 gm.), t.i.d., and a salt bath every day were also ordered. Medicinally, I prescribed 2 grains (.12 gm.) of the ammoniated citrate of iron in freshly expressed orange juice. This was also too irritating to the bowels, but after reducing the dose so that he might receive 1 grain of the iron and a half drachm of the orange juice twice a day, a marvellously rapid improvement was seen, which soon terminated in complete recovery."

Dr. Cheadle says that fresh milk possesses, in addition to the other essential elements a mysterious anti-scorbutic element. Fresh milk, of necessity, is the antiscorbutic food of infancy. Imperative as its use is, Professor Hollopeter was unable to employ it in the case under his charge until he added Mellin's Food to the fresh milk, when all difficulty ceased. Mellin's Food, prepared with fresh cow's milk, contains the antiscorbutic element, and it will not produce scorbatus, but on the contrary will prevent it.

Respectfully yours,  
DOLIBER-GOODALE CO.

The Forty-sixth Annual Session of the AMERICAN MEDICAL ASSOCIATION will be held in Baltimore, Md., on Tuesday, Wednesday, Thursday and Friday, May 7, 8, 9 and 10, commencing on Tuesday, at 10 A.M.

## ASSOCIATION NEWS.

**Secretary's Notice.—The Certificate System.**

PHILADELPHIA, March 28, 1895.

Each person when purchasing a ticket to Baltimore must pay full fare, taking receipt of the agent at the time; this signed by the Permanent Secretary at the meeting enables the purchaser to buy a return ticket for one-third fare. These certificates are not transferable, and should one be offered by any one not entitled to it, the Association will be required to pay the penalty. These are good but three days after the adjournment of the Association. The sale does not begin until three days before the meeting. Special arrangement has been made for the American Academy of Medicine, so that its members can obtain tickets early enough to attend its sessions, which begin May 4.

The following railroads have given excursion rates: Alabama Great Southern; Alabama Midland; Atlantic Coast Line; Atlanta & Florida; Atlanta & West Point; Brunswick & Western; Charleston & Savannah; Central Railway of Georgia; Cincinnati, New Orleans & Texas Pacific; East Tennessee, Virginia & Georgia; Georgia; Georgia Pacific; Georgia Southern & Florida; Jacksonville, St. Augustine & Indian River; Knoxville, Cumberland Gap & Louisville; L. & N.; Marietta & Northern Georgia; Memphis & Charleston; Morristown & Cumberland Gap; Nashville, Chattanooga & St. Louis; Pennsylvania; Port Royal & Augusta; Richmond, Fredericksburg & Potomac; Savannah, Florida & Western; South Carolina; Southern Railway and Western Atlantic.

Now we have all roads including those under the Western Trunk Line Passenger Committee. The New York & Boston Lines Passenger Committee have just agreed to a fare and a third. This includes Boston & Albany; New York & New England; New York, New Haven & Hartford; Old Colony; Fall River; Norwich; Providence; Stonington. The Boston Passenger Committee adds to these Boston & Maine; Central Vermont; Concord & Montreal; Fitchburg; Maine Central; Portland & Rochester.

The Trunk Line Association, includes the Grand Trunk Railway; New York, Connecticut & Hudson River; West Shore; N. Y. O. & W.; N. Y. L. E. & W.; Del., Lackawanna & Western; Lehigh Valley; Central of New Jersey; Philadelphia & Reading; Pennsylvania; Baltimore & Ohio; Chesapeake & Ohio.

W. B. ATKINSON, Secretary.

**Section on Neurology and Medical Jurisprudence.**—Daniel R. Brower, M.D., Chicago, Chairman; T. D. Crothers, M.D., Hartford, Conn., Secretary.

## HYPNOTISM.

1. Hypnotism; its Uses and Uncontrolled Abuses, by William Lee Howard, Baltimore, Md.
2. Medico-Legal Studies of Hypnotism, by Charles K. Mills, Philadelphia, Pa.
3. Medico-Legal Relations of Hypnotism, by Hon. Clark Bell, New York City.
4. Duplex Personality and its Relations to Hypnotism and Lucidity, by R. Osgood Mason, New York City.
5. Difficulties in Eliminating Fraud from Hypnotic Phenomena, by Charles W. Burr, Philadelphia, Pa.
6. Hypnotism in General Practice, by J. S. Eskridge, Denver, Colo.
7. Therapeutics of Hypnotism, by S. Allison Hodges, Richmond, Va.
8. Hypnotism in the Management of Inebriety, by T. D. Crothers, Hartford, Conn.
9. The Psycho-Physics of Sleep, by W. Xavier Sudduth, Minneapolis, Minn.
10. Hysterical Amaurosis and Pseudo-Meningitis, with Report of a Case Treated by Hypnotism, by Hugh T. Patrick, Chicago, Ill.

## ELECTRICITY.

11. Observations on some Characteristics and Relations of the Dynamic and Static Forms of Electricity, by A. D. Rockwell, New York City.
12. Treatment of Esophageal Stricture by Electrolysis, by W. S. Watson, Fishkill-on-the-Hudson, N. Y.
13. Sinusoidal Electrical Current and its Practical Uses, by J. H. Kellogg, Battle Creek, Mich.

14. Electro-Therapeutic Technique in the Treatment of Neurasthenia and Nervous Prostration, by G. Betton Massey, Philadelphia, Pa.

15. Electricity in the Treatment of Ocular Neuralgia, by Horace M. Starkey, Chicago, Ill.

16. Electricity in the Treatment of Exophthalmic Goitre, by Robert Newman, New York City.

17. Electric Light Bath; its Uses in the Treatment of Diseases, by J. H. Kellogg, Battle Creek, Mich.

18. Electricity in the Treatment of Chronic Neuritis, by James C. Gill, Chicago, Ill.

## EPILEPSY.

19. On the Relation of Sex to the Prognosis of Epilepsy, by William Browning, Brooklyn, N. Y.

20. The Medical and Surgical Treatment of Children before the Epileptic Habit is Fixed, by E. D. Ferguson, Troy, N. Y.

21. Therapeutics of Epilepsy, by Horatio C. Wood, Philadelphia, Pa.

22. Practical Treatment of Epilepsy, by Frederick Peterson, New York City.

23. The Value of Craniotomy in Epilepsy and Imbecility, by Charles L. Dana, New York City.

24. The Technique of Craniectomy for Epilepsy and Imbecility, with exhibition of New Instruments, by Seneca D. Powell, New York City.

25. Reflex Causes of Epilepsy, by Wharton Sinkler, Philadelphia, Pa.

26. Epileptoid Attacks of Reflex Crises Curable by Surgery, by Robert S. Morris, New York City.

27. Supplementary Treatment of Epilepsy, by A. N. Williamson, New London, Conn.

28. Relations of Food to Epilepsy, by Edward M. Schaeffer, Baltimore, Md.

29. The Limitations of Surgical Operations as a Means of Relief in the Cure of Epilepsy, by Thomas H. Manley, New York City.

30. Some Non-Medicinal Suggestions for the Treatment of Epilepsy, by Samuel J. Fort, Ellicott City, Md.

31. A Remarkable Case of Epilepsy, by W. S. Whitwell, San Francisco, Cal.

32. Solanum Carolinense in the Treatment of Epilepsy, by C. S. Barber, Brooklyn, N. Y.

33. Moral Treatment of Epilepsy, by H. M. Bannister, Chicago, Ill.

34. Surgical Treatment of Epilepsy, by Albert Vanderveer, Albany, N. Y.

35. Disorders of Sleep and Automatism in Epilepsy, by Sanger Brown, Chicago, Ill.

## OTHER PAPERS.

36. Notes on the Nature and Treatment of Chorea. Based on Seventy-five Cases in Private Practice, by A. D. Rockwell, New York City.

37. Suggestive Criminality, by Arthur McDonald, Washington, D. C.

38. Transcendental Therapeutics, by Richard Dewey, Chicago, Ill.

39. Some Atypical Forms of Tabies, by Theodore Diller, Pittsburg, Pa.

40. Diagnosis in some Forms of Nervous and Mental Diseases, by Irving C. Rosse, Washington, D. C.

41. Reflex Neuroses, by James K. King, Watkins, N. Y.

42. Post-Active Treatment of Narcotic Habitues, by J. B. Mathison, Brooklyn, N. Y.

43. Paranoia Differentially and Medico-Legally Considered, by C. H. Hughes, St. Louis, Mo.

44. Migraine, its Causes and Radical Cure, by J. B. Kellogg, Battle Creek, Mich.

45. The Neurotic Element in Pulmonary Consumption, by Thomas J. Mays, Philadelphia, Pa.

46. The Degenerate Ear, by Eugene S. Talbot, Chicago, Ill.

47. Right Hemiplegia and Aphasia—a Case, by H. M. Lash, of Indianapolis, Ind.

48. Early Recognition and Proper Management of the Mentally Disturbed, by W. S. Watson, Fishkill-on-the-Hudson, N. Y.

49. Alcoholic Coma coming under Police Care, by L. D. Mason, Brooklyn, N. Y.

50. The Responsibility of Opium, Chloral and Cocain Inebriates, by T. D. Crothers, Hartford, Conn.

51. Notes of an Epidemic of Acute Anterior Poliomyelitis, by C. S. Caverly, Rutland, Vt.

**Section on State Medicine.**—Liston H. Montgomery, M.D., Chicago, Ill., Chairman; Charles H. Shepard, M.D., Brooklyn, N. Y., Secretary.

## PAPERS FOR AFTERNOON SESSION—TUESDAY, MAY 7.

1. Address by the President of the Section, by Liston H. Montgomery, Chicago, Ill.
2. Physical Training in Childhood and Youth as a Preventive of Disease, by C. F. Ulrich, Wheeling, W. Va.
3. Hygiene of the Eyes and Ears in Schools, by B. Alex. Randall, Philadelphia, Pa.
4. Anticipative Treatment of Disease, Organically, Functionally and Specifically, by W. G. A. Bonwill, Philadelphia, Pa.
5. Municipal Hygiene, by Geo. T. Maxwell, Jacksonville, Florida.
6. The Proper Relations of National, State and Municipal Quarantine, by Jerome Cochran, Montgomery, Ala.
7. Sanitation, by Archelaus G. Field, Des Moines, Iowa.
8. Depopulation of Civilized Nations, by James W. Cokenower, Des Moines, Iowa.
9. Tuberculosis and Its Prevention, by Chas. E. Winslow, Albuquerque, N. M.
10. Prevention of Tuberculosis by Feeding, by E. Cutter, New York City.
11. The Use of Vaccine Serum in Variola, by Llewellyn Eliot, Washington, D. C.
12. The Necessity for Increased Hospital Accommodations for the Treatment of Contagious Diseases in Large Cities, by Benjamin Lee, Philadelphia, Pa.

## AFTERNOON SESSION—WEDNESDAY, MAY 8.

13. The Bath in Modern Medicine, by Chas. H. Shepard, Brooklyn, N. Y.
14. A Practical Demonstration on the Natural Facilities for Water Contamination, by R. Harvey Reed, Columbus, Ohio.
15. Importance of State Government Control of Artificial Agencies that may be Productive of Noises, by Augustus P. Clarke, Cambridge, Mass.
16. Reform in Medical Expert Testimony, by S. S. Herrick, San Francisco, Cal.
17. The Gold in Garbage, by Douglas H. Stewart, New York City.
- 18 and 19. No titles given. Drs. Cressy A. Wilbur, Lansing, Mich.; F. E. Stewart, Detroit, Mich.
20. Observations on Hydrophobia and the Pasteur Treatment, by Antonio Lagorio, Chicago, Ill.
- 21, 22 and 23. No titles given. Drs. Granville P. Conn, Concord, N. H.; John L. Davis, Cincinnati, Ohio; W. C. Woodward, Washington, D. C.

## AFTERNOON SESSION—THURSDAY, MAY 9.

24. Symposium on Alcohol: N. S. Davis, Chicago, Ill.; T. D. Crothers, Hartford, Conn.; J. H. Kellogg, Battle Creek, Mich.; I. N. Quimby, Jersey City, N. J.; W. B. French, Boston, Mass.
25. Danger of Alcohol in the Grip, by Chas. H. Shepard, Brooklyn, N. Y.
26. Acute Alcohol Insanity as Distinguished from Delirium Tremens, by John Morris, Baltimore, Md.
27. The Influence of Alcohol upon Urinary Toxicity, by J. H. Kellogg, Battle Creek, Mich.
28. Report of a Series of Psychologic Tests, Showing the Effect of Alcohol in Moderate Doses upon the Nervous System, by Drs. David Paulson and Howard F. Rand.
29. The Treatment of Typhoid Fever without Alcohol, by W. H. Riley, Battle Creek, Mich.
30. Six Grave Cases of Typhoid Fever successfully Treated without Alcohol, by Kate Lindsay, Battle Creek, Mich.
31. Alcohol in La Grippe, by C. H. Shepard, Brooklyn, N. Y.
32. Influence of Alcohol on the Blood, by Geo. W. Burleigh, California.
33. Fatality of Surgical Operations in Alcoholism, by I. N. Quimby, Jersey City, N. J.
34. Some Factors in the Solution of the Alcoholic Problem, by F. W. Grosvenor, Buffalo, N. Y.
35. Alcoholic Intolerance and Predispositions, by T. D. Crothers, Hartford, Conn.
36. Alcohol Anesthesia, by L. D. Mason, Brooklyn, N. Y.
37. Does Alcohol ever Act as Food or as a Generator of any Natural Force in the Living Body? by N. S. Davis, Chicago, Ill.

**Section on Obstetrics and Diseases of Women.**—Franklin H. Martin, Chicago, Chairman; X. O. Werder, Pittsburg, Secretary.

## PRELIMINARY PROGRAM, SESSION 1—MAY 7, 2 P.M.

Chairman's Address, Treatment of Fibroid Tumors of the Uterus, by Franklin H. Martin, Chicago, Ill.

1. The Method of good Operations and bad Fibroids, by Joseph Eastman, Indianapolis, Ind.
2. Advantages of Abdominal Extra-Peritoneal Fixation of Pedicle in Hysterectomy for Fibroids, by Joseph Price, Philadelphia, Pa.
3. Technique of new Method of Abdominal Hysterectomy, by Nicholas Senn, Chicago, Ill.
4. Technique of Supra-vaginal Hysterectomy, by B. F. Baer, Philadelphia, Pa.
5. Present Status of Treatment of Fibroids of the Uterus by Electricity, by A. Laphorn Smith, Montreal, Canada.
6. Abdominal Ligation of the Uterine Arteries for Fibroids, by Byron Robinson, Chicago.
7. Vaginal Ligation of Broad Ligaments for Fibroids, by C. C. Frederick, Buffalo, N. Y.

Discussion.

## SESSION 2—MAY 8, 11 A.M.

8. Hysterectomy for Pelvic Suppuration, by J. M. Baldy, Philadelphia, Pa.
9. Indications for Total Hysterectomy, by Augustus P. Clark, Cambridge, Mass.
10. Total Hysterectomy by a new Vagino-Abdominal Method, by Albert H. Tuttle, Boston, Mass.
11. Vaginal Hysterectomy, by Edgar Garceau, Boston, Mass.
12. The Treatment of the Stump in Oöphoro-Salpingotomy—a new Method, by L. H. Dunning, Indianapolis, Ind.
13. The Treatment of Inflammations of Uterine Appendages, by Augustin H. Goelet, New York, N. Y.

## SESSION 3—MAY 8, 2 P.M.

14. Hysterectomy for Puerperal Infection, by Reuben Peterson, Grand Rapids, Mich.
15. Suppurative Forms of Ruptured Tubal Pregnancy, by Joseph Price, Philadelphia, Pa.
16. Ectopic Gestation—Its Early Diagnosis and Treatment, by S. L. Jepson, Wheeling, W. Va.
17. Diseases of a Reflex Nature Arising from Pathologic Conditions of the Uterus and Appendages, by W. H. Humiston, Cleveland, Ohio.
18. Two Interesting Cases of Pelvic Surgery, by H. R. Holmes, Portland, Oregon.
19. Subject not announced. By Eugene Boise, Grand Rapids, Mich.

## SESSION 4—MAY 9, 11 A.M.

20. Suspensio-Uteri—the proper Method of Performing It and Its Results, by Howard A. Kelley, Baltimore, Md.
21. Vaginal Fixation in Retro-Fixation of the Uterus, by X. O. Werder, Pittsburg, Pa.
22. Ovarian Dermoids—with Cases, by J. E. Cowles, Los Angeles, Cal.
23. The Treatment of Hemorrhagic Conditions of the Uterus by Zinc Amalgam Cataphoresis, by G. Betton Massey, Philadelphia, Pa.

## SESSION 5—MAY 9, 2 P.M.

24. Symposium: (a) The first American Symphysiotomy, by George M. Gould, Philadelphia, Pa.; (b) Symphysiotomy, by Hugh Hamilton, Harrisburg, Pa.; (c) Porro Operation vs. Symphysiotomy, by Byron Robinson, Chicago, Ill.; (d) Discussion.
25. The Therapeutic Action of Chloroform in Parturition, by Bedford Brown, Alexandria, Va.
26. Original Studies on the Obstetrical Forceps with Mechanical Demonstrations, by J. J. E. Maher, New York, N. Y.

## SESSION 6—MAY 10, 11 A.M.

27. The Vaginal Route for Operations on the Pelvic viscera, by Tod Gilliam, Columbus, Ohio.
28. Subject not announced. By E. E. Montgomery, Philadelphia, Pa.
29. Subject not announced. By John Milton Duff, Pittsburg, Pa.
30. A new Self-Retaining Perineal Retractor, by A. E. Rocky, Portland, Oregon.
31. Subject not announced. By Llewellyn Eliot, Washington, D. C.
32. Episiotomy, by Frank A. Stahl, Chicago, Ill.

A few changes will be made in the above program. Those reading papers will be limited in time to twenty minutes, those taking part in the discussions to five minutes each. Those presenting papers will do well to prepare very short abstracts containing the gist of the paper, which may be given to the reporters of Eastern journals for publication.

FRANKLIN H. MARTIN, Chairman.

## SOCIETY NEWS.

**The Nu Sigma Nu Fraternity** will hold its thirteenth biennial convention May 13, 14 and 15 at Minneapolis with its University of Minnesota fraters. The Association has a dozen chapters located in the different medical universities and a membership which includes more than a thousand prominent physicians. It originated at the University of Michigan, the parent chapter being at present at Ann Arbor. The object of the fraternity is the intellectual and moral advancement of medical practitioners and the elevation of the standard of the medical profession. The last convention was held during the progress of the World's Fair at Chicago when the following grand officers were elected: President, Dr. John L. Irwin, Detroit, Mich.; Vice-President, Dr. James T. Christison, St. Paul, Minn.; Secretary, Dr. Thad H. Walker, Walkerville, Canada; Treasurer, Dr. F. G. Stubbs, Chicago, Ill.; Historian, Dr. Ransom J. Parker, New York City, N. Y.; Guard, Dr. John H. Macready, Cincinnati, Ohio. Elaborate preparation is being made by the twin cities for the entertainment of the delegates.

**Philadelphia Pathological Society.**—At the semi-annual conversational meeting of the Philadelphia Pathological Society, to be held on Thursday, April 25, at 8:15 P.M., in the hall of the College of Physicians, northeast corner of Thirteenth and Locust Streets, Dr. George Dock, of the University of Michigan, will deliver an address entitled "Trichomonas as a Parasite of Man." Members of the profession are cordially invited to be present. **AVOUSTUS A. ESHNER**, Secretary.

**Association of American Medical Colleges.**—The sixth annual meeting of the Association of American Medical Colleges will occur at the Rennert, Baltimore, Md., at 2 P.M., Wednesday, May 8, 1895.

## BOOK NOTICES.

**Degeneration.** By MAX NORDAU. Translated from the Second Edition of the German work; 8vo, pages 560; cloth. New York: D. Appleton & Co. 1895.

This work is one of the healthiest tonics of the present century. It is seldom a book is written with such originality, with such keen insight into poor, weak and erring human nature, and although the tendency of the book is distinctly pessimistic, yet it is as well that the full measure of the degeneracy of the present age should be exposed and made clear, as that a foul ulcer or sinus should be probed to its extremity in order that a cure may be effected. Nor is it fair to charge this author with being an unreasonable cynic, for "the plain dealing remonstrances of a friend differ as widely from the rancor of the misanthrope as the probe of the surgeon from the dagger of the assassin."

The work is divided into five books—Book I, *Fin-de-siecle*; which comprises four chapters, as follows: I, the Dusk of the Nations; II, the Symptoms; III, Diagnosis; IV, Etiology. Book II, *Mysticism*, containing six chapters, namely: I, the Psychology of Mysticism; II, the pre-Raphaelites; III, Symbolism; IV, Tolstoism; V, the Richard Wagner Cult, and VI, Parodies of Mysticism.

Book III on Ego-Mania has five chapters, as follows: the Psychology of Ego-Mania, Parnassians and Diabolists, Decadents and Aesthetes, Ibsenism and Friedrich Nietzsche. Book IV on Realism, has two chapters: Zola and his School; and the Young German Plagiarists. Book V, the Twentieth Century, has two chapters on Prognosis and Therapeutics.

It is impossible for an educated man, especially if he be a physician with a metaphysical turn of mind, to begin reading this book without perusing it to the end, as not only is it very interesting reading, but it presents old facts and new theories with such wit and wisdom as to keep one's interest throughout. We can not refrain from giving an extract from this highly original and very timely work. Page 7:

"Let us follow in the train frequenting the palaces of

European capitals, the highways of fashionable watering places, the receptions of the rich, and observe the figures of which it is composed.

"Among the women, one wears her hair combed smoothly back and down like Rafael's Maddalena Doni in the Uffizi at Florence; another wears it drawn up high over the temples like Julia, daughter of Titus, or Plotina, wife of Trajan, in the busts in the Louvre; a third has hers cut short in front on the brow and long in the nape, waved and lightly puffed, after the fashion of the fifteenth century, as may be seen in the pages and young knights of Giovanni Bellini, Botticelli and Mantegna. Many have their hair dyed, and in such a fashion as to be startling in its revolt against the law of organic harmony, and the effect of a studied discord, only to be resolved into the higher polyphony of the toilet taken as a whole. This swarthy, dark-eyed woman snaps her finger at nature by framing the brown tones of her face in copper-red or golden-yellow; yonder blue-eyed fair, with a complexion of milk and roses, intensifies the brightness of her cheeks by a setting of artificially blue-black tresses. Here is one who covers her head with a huge heavy felt hat, an obvious imitation, in its brim turned up at the back, and its trimming of large plush balls, of the sombrero of the Spanish bull-fighters, who were displaying their skill in Paris at the exhibition of 1889, and giving all kinds of *motifs* to modistes. There is another who has stuck on her hair the emerald-green or ruby-red *biretta* of the mediæval traveling student. The costume is in keeping with the bizarre coiffure. Here is a mantle reaching to the waist, slit up on one side, draping the breast like a *portiere*, and trimmed round the hem with little silken bells, by the incessant clicking of which a sensitive spectator would in a very short time either be hypnotized or driven to take frantic flight. There is a Greek *peplos*, of which the tailors speak as glibly as any venerable philologist. Next to the stiff monumental trim of Catharine de Medici, and the high ruff of Mary, Queen of Scots, goes the flowing white raiment of the Angel of the Annunciation in Memling's pictures, and, by way of antithesis, that caricature of masculine array, the fitting cloth coat, with widely opened lapels, waistcoat, stiffened shirt front, small stand-up collar and necktie. The majority, anxious to be inconspicuous in unimaginative mediocrity, seems to have for its leading style a labored rococo, with bewildering oblique lines, incomprehensible swellings, puffings, expansions and contractions, folds with irrational beginning and aimless ending, in which all the outlines of the human figure are lost, and which cause women's bodies to resemble now a beast of the Apocalypse, now an arm-chair, now a triptych, or some other ornament.

"The children, strolling beside their mothers thus bedecked, are embodiments of one of the most afflictive aberrations into which the mind of a spinster ever lapsed. They are living copies of the pictures of Kate Greenaway, whose love of children, diverted from its natural outlet, has sought gratification in the most affected style of drawing, wherein the sacredness of childhood is profaned under absurd disguises. Here is an imp dressed from head to foot in the blood-red garb of a mediæval executioner; there a four-year-old girl wears a cabriolet bonnet of her great-grandmother's days and sweeps after her a court mantle of loud-hued velvet. Another wee dot, just able to keep on her tottering legs, has been arrayed in the long dress of a lady of the First Empire, with puffed sleeves and short waist.

"The men complete the picture. They are preserved from excessive oddity through fear of the Philistine's laugh, or through some remains of sanity in taste, and, with the exception of the red dress coat with metal buttons, and knee-breeches with silk stockings, with which some idiots in eye-glass and gardenia try to rival burlesque actors, present little deviation from the ruling canon of the masculine attire of the day. But fancy plays the more freely among their hair. One displays the short curls and the wavy double-pointed beard of Lucius Verus; another looks like the whiskered cat in a Japanese *kakemono*. His neighbor has the *barbiche* of Henry IV., another the fierce mustache of a lansquenet by F. Brun, or the chin-tuft of the city watch in Rembrandt's 'Ronde de Nuit.'

On ego-mania, the author pays his respects to Oscar Wilde as follows:

"The ego-mania of decadentism, its love of the artificial, its aversion to nature, and to all forms of activity and movement, its megalomaniacal contempt for men, and its exaggeration of the importance of art, have found their English representatives among the æsthetes, the chief of whom is Oscar Wilde.

"Wilde has done more by his personal eccentricities than by his works. . . . It is asserted that he has walked down Pall Mall in the afternoon dressed in doublet and breeches, with a picturesque biretta on his head, and a sunflower in his hand, the quasi-heraldic symbol of the aesthetes. This anecdote has been reproduced in all the biographies of Wilde, and I have nowhere seen it denied. But is a promenade with a sunflower in the hand also inspired by a craving for the beautiful? . . . Be that as it may, Wilde obtained, by his buffoon mummery, a notoriety in the whole Anglo-Saxon world that his poems and his dreams would never have acquired for him. . . . Oscar Wilde apparently admires immorality, sin and crime. . . . The aesthetes carry themselves as if they were the soul of humanity and make a parade of their contempt for the Philistine. They belong, however, to elements of the race which are most inimical to society, insensible to its tasks and interests, without the capacity to comprehend a serious thought or a fruitful deed. This rabble, which claims for itself a top place in the scale of intellectual rank and freedom from the restraint of all moral laws as its most noble privilege, is certainly baser than the lowest scavenger. Ego-maniacs, decadents and aesthetes have completely gathered under their banner this refuse of civilized peoples, and march at its head."

Had Nordau access to the court papers and to the Marquis of Queensberry in advance of the recent *denouement*? It seems very unlikely; but after all it is critical science which has enabled him thus early to point out the fact that persons of Wilde's stamp are not only "degenerates" but "perverts." We repeat, as it was said in the beginning, that this book will prove to be one of the most healthy tonics to offset the insidious invasions of the false theories of a degenerate age.

## PUBLIC HEALTH.

**Disposal of Garbage.**—There is promise, in the increased attention now being paid to the disposal of garbage by sanitarians, physicians and engineers, of a satisfactory solution of the vexing problem. Recent papers by Drs. Thomas H. Manley and Douglas H. Stewart, of New York City, as well as the paper on the "Collection and Disposal of the Refuse and Garbage of Large Cities," presented by Mr. W. F. Morse at the Montreal meeting of the American Public Health Association, clearly indicate the lines on which this solution must be attained. Possibly Dr. Manley is a little optimistic in his trust that the individual may be educated out of his indolent and thriftless habits and so be made to do any important share of the work necessary for the inoffensive disposal of the waste and refuse his daily life creates. But the effort is certainly worth trying, whether it succeeds in making "this material, now treated as offal and a nuisance, a source of revenue to every householder," or not.

**Mortality by Influenza in New York in February.**—The monthly *Bulletin* of the New York State Board of Health charges 3,000 deaths to la grippe in the present epidemic. Of this number 1,600 deaths are estimated in the month of February, and 1,400 in January, or 57 each day in the second month against 45 each day in the first month. A like mortality is predicted by the reporter in March. The mortality by influenza is partially masked under an excessively high total by consumption, whose mortality is always accelerated and intensified by that other cause. Deaths from old age as is usual in epidemic winters were precipitated; the enormously large death rate in old people has been repeatedly commented upon as a feature of the epidemic prevalence of influenza in London and Glasgow in the present winter. There was a great increase in the respiratory deaths, and also in that "waste-basket of causes," the unclassified. Of this latter, some of which was influenza doubtless, the total for February was 1,621 in a total of 10,771 deaths; a plan of statement

that leaves every subject of comparison dubious and debatable.

**Stringent Rules Governing the Pollution of Streams.**—The New York State Board of Health has passed certain regulations that have operated very favorably for the protection of the water supply of Brooklyn. As a consequence, the agricultural use of quite a large acreage has been restricted at Springfield on Long Island. The farmers having grievances on this account will sue the city of Brooklyn for indemnification for the lost use of their farm lands that border on that city's water courses. The rules of the State Board were put in force in August, 1894; the particular clause in those rules which seems to have aroused a feeling of antagonism among the Long Islanders is one which prohibits the fertilizing of land within fifty and one hundred feet of the streams. The enforcement of this law will throw into disuse large tracts of land which have heretofore been cultivated as vegetable gardens by the tenants of the houses. This means a great depreciation in the value of the property, the owners say, and they are inclined to question the power of the city to practically condemn the land without the payment of damages. The interested parties are considering the matter with a view of petitioning the authorities to so amend the objectionable law that their tenants may continue in the same old way so far as concerns the cultivation of their gardens.

**Beef vs. Horseflesh.**—What is termed a "beef famine" is now impending in this country, simultaneously with which it is noted that hundreds of thousands of wild horses are roaming our Western plains wasting the grazing needed for cattle. These animals have little or no market value—\$2 being the highest quoted price—and yet the consumption of horseflesh is increasing so rapidly in Europe that worn-out horses for which butchers formerly paid only from \$5 to \$10 are now worth \$45 to \$50. Mr. E. W. Tingle, United States Consul at Brunswick, Germany, sees here a great opportunity for American packers. Upward of 20,000 horses are annually slaughtered for sausage meat in the Paris abattoirs alone. These animals are carefully examined by competent veterinary authority and only absolutely healthy ones are accepted. The *chevaline*, or horse sausage, has become so popular that the *Commite d'Hygiene* of Paris has been appealed to, to discriminate against its sale by some form of label. The *Commite* has adopted a method devised by two German chemists, MM. Edelmann and Brautigan, of distinguishing between the *chevaline* and ordinary sausage. This consists in adding to a bouillon of the sausage meat, acidulated with a 5 per cent. solution of commercial nitric acid, a few drops of iodized water or Gram's solution, which are allowed to flow down the sides of the tube containing the bouillon. With the horse bouillon there is formed a violet-red-brown ring, which is not developed in veal, beef, mutton, pork, dog or chicken bouillon. As determined by this test, all horse sausages will be henceforth labeled accordingly, but it is not believed that the label will diminish the popularity of the *chevaline*. The proper place for its manufacture is, however, as Mr. Tingle might have suggested, in our Western States where wild horses multiply so rapidly that stallions are declared to be *feræ nature* and may be shot down on sight.

**Winter Mortality of Chicago.**—Dr. A. R. Reynolds, Health Commissioner of Chicago, compares the mortality of the winter quarter of 1895, ended March 31, with the mortality of the corresponding period in previous years. The comparison shows an increase of 27 per cent. in the total mortality of 1894. The total deaths from all causes during the quarter were 6,648—an annual rate of 16.62 per thousand of 1,600,000 population; the average death rate of the corre-

sponding quarter for the previous ten years, 1885-1894 inclusive—was 19.10 per thousand; the lowest in 1894—13.08 per thousand; the highest in 1891—23.40 per thousand. Acute lung diseases, complicated with influenza, are responsible for the increased death rate. This group, pneumonia, bronchitis and influenza, shows an increase of 143 per cent., as compared with the winter quarter of 1894, and pulmonary consumption shows an increase of 12.5 per cent. The Commissioner says that the prevalence of influenza has been more general than is indicated by the number of deaths (142) returned as from that cause. To its complications are to be attributed the great severity and fatality of pneumonia and bronchitis, as well as a large number of non-fatal cases of illness of masked or obscure symptoms which have affected the tone of the general health of the community and especially of the aged and enfeebled. It is, however, the unusual seasonal influences which have caused the increased death rate, rather than the prevalence of influenza. The mean temperature for the month of January was 6.8 degrees lower than the average January temperature of the previous twenty-five years, and the extremes ranged between 9 degrees below zero to 51 degrees above. During February the deficiency in temperature and the range of extremes was still more marked; the mean temperature was 10.7 degrees below the normal, the accumulated deficiency of daily mean temperature at the close of the month was 50.4 degrees, and the extremes ranged from 15 degrees below zero on the 8th of the month to 61 degrees on the 28th—a range of 76 degrees. More than half the month was cloudy or partly cloudy, with an excess of humidity. During this month the deaths from pneumonia rose in number from 163 in January to 444, or nearly one-half of the total number for the quarter.

Concerning smallpox, Dr. Reynolds says: "With the close of the first quarter of 1895, it seems to be entirely safe to say that the fourth serious—and at one time the most threatening—visitation of smallpox upon Chicago is at an end. The disease has steadily declined since June, 1894, that is to say, from a period within thirty days after the great vaccination campaign was fairly inaugurated. That work is now conceded, both in this country and abroad, to be one of the most signal triumphs of preventive medicine on record, and a feat of sanitary administration without a parallel in respect of magnitude and diversity of population dealt with, of successful avoidance of overt opposition to the enforcement of health ordinances and regulations, and of direct results in the prompt check and ultimate suppression of the ravages of a pestilence. In many respects there is a striking parallel between the four great smallpox epidemics in Chicago—the first beginning in December, 1862, and continuing to June, 1864; the second beginning in October, 1871, and continuing to January, 1874; the third beginning in April, 1880, and continuing to June, 1883; and the latest beginning in June, 1893, and now substantially at an end. The features common to these epidemics are the great historic events, involving large movements of population, transient or permanent, which occurred at the corresponding periods, as when, in 1862, during the Civil War, Chicago received large numbers of Confederate prisoners and of immigrants, both of which classes repeatedly introduced the smallpox contagion; again, in 1871-72, when the rebuilding of the city after the Great Fire attracted thousands of immigrants, both domestic and foreign; again, in 1880, when there began the heaviest immigration movement in the history of the country; and, finally, in 1893, the World's Fair year. Preceding each of these epidemics there had been periods of entire freedom from the disease, and the few scattering cases which broke these periods were readily dealt with and created no alarm, so that vaccination became more and more neglected and the aggregation of susceptibles larger and larger until the explosion ensued. In neither of the first three epidemics was it found feasible to secure vaccination on any adequate scale—in fact, Dr. Rauch, in his "Sanitary History of Chicago," says there was no provision for gratuitous vaccination in the epidemic that began in 1862, and that "the neglect of this precautionary measure was the cause of the daily increase of cases which continued for nearly two years after." And again, in speaking of the epidemic of 1871-74, the same eminent authority shows that it was not until "January, 1874, that the diminished susceptibility of the population and the amount of vaccinal protection which had been secured resulted in a marked decrease." In the last preceding epidemic, that of 1880-83, greater effort was

made to secure vaccination, but only 48,900 vaccinations were performed in 1881 and 110,540 in 1882—or a little more than 28 per cent. of the population in the two years. It was not until the National Board of Health undertook the inspection and vaccination of every unprotected immigrant arriving in Chicago that this epidemic was materially checked in January, 1883. Last year a total of 1,069,500 free vaccinations were performed—586,000 in the month of May. The accompanying diagram shows the result:

The solid black line indicating the course of this epidemic, shows the highest mortality in May, 1894, when there were 253 deaths, or 1.61 to each 10,000 of population. The decline since then is striking when compared with the broken lines indicating the course of the previous epidemics at corresponding months. The slight increase shown in January was caused by importations from Roby, the drainage canal and other points outside the city; that shown in March, by a colony of negroes from Tennessee and by refugees from the South.

As an epidemic, smallpox ceased in Chicago within thirty days after it became possible to secure an adequate supply of pure and efficient vaccine.

Comparative figures of the four epidemics:

Epidemic of	Highest Monthly Mortality.	Death per 10,000 of Population.
1862-64 . . . . .	January, 1864	3.66
1871-74 . . . . .	March, 1872	2.64
1880-83 . . . . .	January, 1882	6.15
1893-95 . . . . .	May, 1894	1.61

Mortality at the close of the first quarter of 1895, and for corresponding periods:

March, 1864,	2.46 deaths per 10,000 of population
" 1873,	0.95 " " "
" 1882,	4.67 " " "
" 1895,	0.22 " " "

## MISCELLANY.

**Neurological Infirmary at Flushing, N. Y.**—The following named physicians have formed a syndicate for the purpose of establishing at Flushing, Long Island, a hospital to which they can send their patients—Drs. E. G. Janeway, F. S. Dennis, J. D. Bryant, W. T. Bull and E. M. Hamilton. The start will be made with rooms for thirty patients, under the personal charge of Drs. Killilea, Constable and Burchard. The nervous diseases will have the first claim upon the institution.

**Lay Comments on a Lithopædion.**—A surgical operation was recently performed at the Religio-Medici General Hospital at X—, for the removal of a lithopædion from an adult male. The operation was successful as to the delivery by laparotomy, of the fetal remains, but the parent did not survive. Two ladies traveling in one of our public conveyances were overheard discussing the singular operation. One of them remarked: "So odd, was it not, and in a young man, at that." "Yes," replied the other in a subdued tone of voice, "and a bachelor too."

**Dentists' Relations Not Confidential.**—During the trial of the case of *The People vs. Stonewall J. De France* for forgery,

the defense attempted to raise a question of identity, for which purpose they showed that the teeth of the accused were entirely different from those of the person committing the forgery as alleged. In rebuttal, a dentist of Detroit was cited who testified that subsequent to the date of the forgery he had inserted three false teeth in the place of two incisors for De France. The case was carried up on appeal to the Supreme Court of Michigan, on the ground that the trial court had erred in admitting the dentist's testimony, claiming that his knowledge was privileged as between physicians or surgeons and patients. The Supreme Court affirmed the verdict of conviction and held that the terms "dentist" and "physician or surgeon," as the latter are used in the statute covering this point, are not interchangeable and that a dentist's relations with his patient can not be considered confidential as is the case with a physician or surgeon.

**Quackery in China.**—In the far-off province of Yun-nan of southwestern China there are divisions in medical practice not unlike those America and Europe know. There are "regulars" and there are quacks—and it is difficult to tell which of the two are the more unsafe. A missionary writes to one of our cotemporaries: "Quack doctors are commonly to be met with at every fair and on every market day, and they interfere not a little with the regular and resident practitioners of the city. So far as the people are concerned it makes but little difference which of them treats their cases, for the local and the itinerant doctors are alike ignorant of the first principles of anatomy, physiology or medicine."

**Legislation Against Coroners in New York.**—Although the present constitution puts it in the power of that State Legislature to wipe out the old and much abused coronial system, very little progress has been made. A bill has been introduced and shelved at the instance of the present officers, on the ground that the latter should have an opportunity to "examine" the bill. The bill, if accepted, will be very far from satisfactory to the reform element that has in view a complete substitution of the old system, by another resembling the medical examiner system of Massachusetts. There are now four coroners for New York County, with a salary of \$5,000 and \$3,000 for expenses. If the new plan is adopted there will be, after the term of the present officers shall have expired, one coroner at \$10,000 and a like amount for expenses and clerk hire. The most important feature of the bill is one that authorizes the coroner to appoint six qualified physicians as medical examiners at salaries from \$3,000 to \$5,000. Coroners' juries will be abolished. An inquest will be held by the coroner with a stenographer present to take down the evidence.

**Ambulance Cars on Trolley Lines.**—Dr. Z. Taylor Emery, Health Commissioner of Brooklyn, it is reported purposes to add a trolley service to the very ample ambulance system of that city. As we believe, Dr. George Homan, Health Officer for St. Louis, has been the first to secure that public service for a city. He attempted to induce the Legislature to pass a law providing for the service, but when this effort failed he succeeded in interesting the officers of the railroad companies in the subject. As a result a trolley car has been equipped as an ambulance and it will soon be running on schedule time over all the trolley lines in the city. It is not intended that the car should take the place of the emergency ambulance service. A large proportion of hospital patients are transferred from houses and could await the arrival of the car on its schedule time. The transfer can be made by the car much more comfortably than by the ordinary ambulances. The St. Louis car is thirty-three feet long and is divided into two compartments by a movable partition. It is lighted and heated by electricity and con-

tains reclining chairs, stretchers and such surgical appliances as may be needed, and is manned by a trained nurse and a surgeon. Dr. Homan believes the car will give great satisfaction not only to the hospitals, but to the people who are compelled to use it.

**"Hobbies."**—We presume medical journals, like everybody else, have the right to ride hobbies; but when one is ridden to such extremes as our Pittsburg cotemporary does, that of advertising in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, it makes us very weary. We could have some patience with our neighbor's crotchets so long as he practiced what he preached. But now that he is advertising Fairchild's "Panopepton," "Baker's Codliver Oil," "Mackintosh Supporters," "Alloinum," Marchand's "Peroxid," Fehr's "Compound Talcum," Boehringer's Cocain," Parke, Davis' "Kola Cordial," together with patent adjustable eyeglasses, mineral waters without end, Hoff's "Extract of Malt" liquors, wholesale and retail, private maternity retreats, etc., etc., all excellent in their way, but no better or no worse than many of those advertised in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, we think it is time to let up on the old "chestnut" of advertising in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*.—*Cleveland Medical Gazette*.

**Did Marie Stuart Have the Influenza?**—Nothing reconciles your true Briton to any physical affliction so thoroughly as that he shall have shared it in common with royalty. The recent prevalence of influenza in England and Scotland has caused a search to be made for illustrious sufferers from the malady, the latest result of which is that Mary, Queen of Scots, had an attack in November, 1562, of a distemper "which no doubt was influenza." It was thus described by Thomas Randolph in a letter to Cecil: "May it please your Honours, immediately on the Queen's arrival here she fell acquainted with a new disease that is common in this town, called here the New Acquaintance, which passed through her whole Court, neither sparing lord, lady, nor damoiselle, not so much as either French or English. It is a pain in their heads that have it, and a soreness in their stomachs, with a general cough that remaineth with some longer, with others shorter time, as it findeth apt bodies for the nature of the disease. The Queen kept her bed six days. There was no appearance of danger, nor many that die of the disease, except some old folk. My Lord of Murray is now presently in it; the Lord of Liddington hath had it." It may be that the "New Acquaintance" was, in fact, influenza, but Hirsch makes no record of the disease in England until 1688. There was, however, a general diffusion of influenza in Europe in 1557 and in Italy in 1562. Mary left France for Scotland in August, 1561, and it might be presumed that she brought the disease with her if it were not that Randolph asserts that the "New Acquaintance" was already common in Scotland before her arrival.

**An Areopagus Needed.**—Reviewing Dr. H. M. Bannister's authorized translation of "A Practical Manual of Mental Medicine," by Dr. E. Régis, the *Dublin Journal of Medical Science* discloses in its prefatory remarks, an unusually intimate acquaintance with matters and things American. Referring to the fact that this volume is the first instance of a work treating of mental alienism, written by an alienist, translated by an alienist and, under the direction of an alienist, printed and bound by the insane—the inmates of the Utica Insane Asylum—the *Journal* says: "Recently there has been, at the Utica Asylum, one of those crises which periodically disturb the government of all such places. The lay committee and the medical staff having differed—as we understand, originally on the subtle and difficult question of how far it was the medical superintendent's duty to keep the committee men supplied through the winter with flowers and grapes grown in the asylum greenhouses—it was decided by the more powerful party that changes must be made, and one of these has been to suppress the Utica press, to force the *American Journal of Insan-*

## LECTURES.

### LECTURES ON INTRACRANIAL SURGERY.

V—BRAIN TUMOR AND ITS SURGICAL TREATMENT.

BY EMORY LANPHEAR, M.D., PH.D.  
ST. LOUIS, MO.

Operation for brain tumor is certainly an enticing one—the possibilities are so great. The first inducement is the fact that the result from the expectant plan is invariably fatal, generally within two years; the sometimes wonderful changes apparently wrought by internal medication are deceptive—they do not prolong life; and this is believed by some to be true even of syphilitic intracranial growths. A second incentive is that in most instances the almost exact position of the neoplasm can be determined by the well-formulated principles of cerebral localization. And the third is that in a large percentage of cases the growth is situated within reach of the surgeon's knife. The objections to operative treatment are: 1, the possibility of erring in the selection of the point for trephining; 2, the recurrence of the disease; and 3, the high mortality.

While it is possibly true, as Agnew said, that "the results of operations for extirpation of brain tumors can not be considered as particularly brilliant," yet from a study of the cases I have operated on and from the excellent results in the work of many other surgeons, I am compelled to agree with the statement of Bartlett, of Philadelphia, that "in the absence of any reliable cure for brain tumor, one is not justified in waiting long for results if the symptoms are such as to enable him to locate the lesion," providing that it be accessible.

As to the question of location, according to M. Allen Starr, about one-third of all cases occur in the basal ganglia, internal capsule, corpora quadrigemina, crura, pons and medulla, and so are inoperable. Of the remaining two-thirds a considerable percentage must be amenable to surgical treatment. In only four out of seventy-two operations collected by Knapp, the tumor could not be removed. In all the cases I have examined, in only one was I satisfied the growth could not be reached. But even if one should err in attempting to locate the tumor and it should not be found, a large opening in the skull and dura will afford much temporary relief if the dura be not tightly sutured and the fragments of bone be not replaced. Thus in a case reported by Fischer, of Breslau, much improvement occurred from such an operation. And in one of double trephining by Kocher, of Berne, to relieve symptoms when localization was impossible (the only pronounced features being choked disc, deterioration of vision, headache and unsteady gait) an opening was made anteriorly in the frontal region with some bulging of the dura, and one posteriorly just below the tentorium cerebelli

where a hernia cerebri formed which was removed by a Volkmann's sharp spoon and the wound closed; union by first intention was secured; four days after the operation the congestion of the discs had entirely disappeared and sight had improved; seven weeks after operation the general condition was much better than it had been, the gait was steadier, the headache gone, etc. To be sure death ultimately resulted in both cases, but the patients were given a short respite and their final days rendered less painful.

If the tumor can be located I believe the indications are to remove it even though it gives but transient relief. Some cases have been *cured* beyond any question, and the cerebral functions, strange as it may seem, restored after removal of even large intracranial growths. For example, Dr. H. H. Mudd, of St. Louis, has reported a case in which an immense echinococcus mass was removed from the brain of a girl 12 years old, the diseased mass being larger than a hen's egg and located in the motor region, reaching from the convexity to the lateral ventricles; after shelling out the tumor the wound was irrigated and the scalp sutured; the hole, large as it was, soon closed up and the motor disturbances disappeared, viz., the tremor and hemiparesis accompanied by hemianopsia and choked disc. In one of my cases I removed a tumor springing from the dura, almost as large as the one just mentioned, and the brain tissue appeared so greatly altered that it seemed as if there never could be restoration of function; yet the symptoms entirely disappeared in due time. Bremer explains the return of function after such colossal defects by the assumption that "the fibers of the corona radiata are not destroyed, but merely pushed asunder; though perhaps the myeline sheaths of these fibers are atrophied by pressure the more resisting axis-cylinders preserve their continuity and so complete regeneration can occur."

Cerebral tumor is of much greater frequency than is generally supposed. Many hundreds of cases have been recently published; Knapp, of New York, alone having compiled more than eleven hundred records of cases and this is a very incomplete report.

The question of fatality is an important one, for while the patient knows that death is inevitable without operation, he is anxious not to have his days cut short by an ambitious surgeon; yet wishes to avail himself of any possibility of cure. What are the chances of life and death? Of seventy-two cases operated on, according to Knapp's figures forty-one recovered and thirty-one died from the operation; in seven cases, (Horsley six, Knapp one) of trephining for relief of pressure alone there was no death. The death rate in Knapp's statistics is 43 per cent., but this is much higher than would be shown by recent cases if collected. The mortality under our present improved technique I place at about 30 per cent., and with increased experience we can reduce this. Of

twenty-eight cases of trephining for deep intracranial troubles in my own work five died—a fatality of less than 18 per cent.; while in my eight cases of tumor operated upon there were two deaths<sup>1</sup>—a mortality of 25 per cent. While this looks like a formidable death rate it must be remembered that nearly if not quite 100 per cent. die if not subjected to operation.

#### VARIETIES.

Most brain tumors are either syphilitic or tubercular—occurring as gummata or caseous masses respectively, the latter chiefly in young subjects. Other forms more rarely met are osteomata, fibromata, gliomata, sarcomata, carcinomata, cholesteomata and cysts. Tumors other than those just mentioned are very rare, but occasionally cysts of the arachnoid, hydatids, plexiform angio-sarcomata, endotheliomata, etc., are met. The combined tables of Starr, Birch-Hirschfeld and Bernhardt give 1,098 tumors of which there were

Tubercle . . . . .	371
Glioma . . . . .	165
Sarcoma . . . . .	162
Gumma . . . . .	69
Cysts . . . . .	47
Carcinoma . . . . .	28
Glio-sarcoma . . . . .	18

Myxomata, neuromata, osteomata and other rare growths complete the list. Special consideration of some of these varieties is necessary before proceeding with the discussion of the general features of tumor.

1. *Gliomata*.—These growths, if not very vascular, may be removed easily. They are almost always found in the gray matter. If thoroughly extirpated recurrence is not probable and all symptoms may disappear. Thus P. Postemski, of Rome, on May 24, 1891, exhibited to the Royal Academy at Rome a case upon which he had successfully operated some months before; all the symptoms were gone and the woman was (apparently) restored to health.

2. *Fibromata*.—Fibromata, though rare, are always easily accessible as they spring from the meninges; and can therefore be readily extirpated. In the few cases I have been able to discover in recent literature, success has been the result invariably.

3. *Carcinomata*.—Carcinomata are not infrequently met in the brain; they are attended with just as great danger of return after removal as in any other part of the body. They commonly have a mass of hyperemic and softened brain tissue around the morbid growth, but in spite of this they may be cut away, the adjacent tissue being cleaned out by a Paquelin cautery. Personally I have met but one case of carcinoma of the brain; it was so extensive that I did not dare remove it, and I believe it was good surgery to leave it untouched, though the patient lived less than six weeks.

4. *Cysts*.—Cysts are comparatively rare. They can ordinarily be removed without difficulty, though in a case in the practice of Dr. John Punton, of Kansas City, (reported in the *Kansas City Medical Index*, February, 1893) operated upon by myself, there was not sufficient integrity to the cyst wall to allow of removal; the cyst was therefore simply opened and drained. And experience of numerous operators has shown that opening and draining cerebral cysts

gives almost as good results as does similar treatment in cerebral abscess.

5. *Gummata*.—Concerning syphilitic growths Horsley remarks: "Cerebral gummata should always be removed—iodid of potassium palliates but does not cure them"—a statement in which all who have studied the subject must concur. The assertion of Agnew may be taken as especially applicable to this class of cases: "The triumph already achieved by the conjoined labors of the neurologist and surgeon may be the harbingers of still greater ones in the future." I have operated twice for syphilitic intracranial growths—with two successful results. One case which I saw in consultation with the late Dr. J. W. Jackson, Chief Surgeon of the Wabash Railway system, gave all the characteristic signs of cerebral gumma, including choked disc, paralysis, etc., and recovered under the long-continued use of more than two ounces of iodid of potassium daily and prolonged residence at Hot Springs, Ark. There is a possibility of a wrong diagnosis in this case, but I was sufficiently certain of the existence of the tumor and its location that I would have operated had consent been obtainable. I believe yet, that operation would have been better treatment, for though several years have elapsed without any return of cerebral symptoms, there is quite a probability of trouble for this patient in the future.

6. *Sarcomata*.—Sarcomata found within the cranium are either of the spindle-celled or myeloid varieties. They may spring from the diploë, widely separating the tables and at last breaking through with much suffering, especially if the growth be directed inward. In most instances they develop in the dura mater; the question of extirpation in such cases is of vital importance and is still undecided. They frequently perforate the cranium and spread beneath the scalp, giving a distinct pulsation in the mass, reducibility when small and a characteristic sharp opening in the skull. I believe excision to be the correct thing, the only question which arises being justifiability in advanced cases; and here the subcutaneous injection of the toxins of the streptococcus of erysipelas and of the bacillus prodigiosus, as advised by Colley, certainly should be practiced when extirpation is found to be impossible. But increasing experience in cerebral operations and (particularly) observation of several cases of extensive destruction of the dura, lead me to the conclusion that we may safely remove a much larger portion of the dura than we are wont to believe. I have taken away an area one and one-half by three and one-half inches without apparent ill effect. If the scalp and periosteum can be brought over the hole in the skull so as to completely close it, the brain gets on very well—in certain parts of it at least. In view of which I am of opinion that operation for sarcomata might be successful in more cases than now reported were surgeons less saving of the dura; and even should permanent paralysis result, such a termination is far better than death from the neoplasm.

7. *Osteomata*.—Those concerning us in our study of cerebral surgery are of the inner table or diploë (enostoses). As a rule they are of slow growth and may be left alone; but if serious symptoms arise, as a displacement of the eyeball from osteoma of the frontal sinus, or indications of intracranial pressure, they must be removed.

8. *Tubercle*.—This is the form of tumor generally

<sup>1</sup> One was a cyst of the arachnoid, with hemiplegia and imbecility; from the Indian Territory, referred to me by Dr. O. W. Krueger. The second, sarcoma of the dura, from Dr. J. H. Thompson, of Kansas City. Reports will be published later.

found in childhood and is, it is asserted, the most frequent of all intracranial growths. Dana says it is most often located in the cerebellum. The tubercular tumor is usually irregularly round in shape and varies from one to two inches in diameter, of a grayish-yellow color, not of itself vascular but frequently surrounded by inflamed or even softened brain tissue. These growths are often connected with the central parts of the brain but are also not infrequently developed in the meninges in the parietal region. In a fairly large percentage of cases they are within the safe area of surgical work.

9. *Enchondromata, Lipomata, Angiomata and Neuromata.*—These forms are all rare and demand no special consideration. When accessible they are to be removed just as would be the case if situated in any other part of the body.

#### SYMPTOMS.

The importance of thoroughly understanding the symptoms of brain tumor can not be over-estimated by the student, because the diagnosis as well as the location of the disease must be determined by a proper interpretation of even the most minute signs. And the greatest diversity of symptoms can not but be noted in different cases, since the characteristics must vary according to the location of the tumor, its rapidity of growth and the age of the patient—so the physician must be careful not to be led astray. It is my design to merely call attention to the most prominent features of the trouble as manifested by its development in different regions.

Generally, when the lesion originates in the frontal lobes the patient first notices a headache which gradually becomes more intense and is persistent; later, the exacerbations assume an agonizing character. Then follows stupor, disturbed sleep, loss of memory, and optic neuritis—sometimes with vomiting; these are associated with more or less pronounced psychical disturbances, *e.g.*, lack of judgment. Yet the frontal convolutions belong to the "latent areas" and so sometimes very grave conditions may exist without marked manifestations.<sup>2</sup> When the tumor has developed sufficiently to encroach upon the motor or speech areas, focal symptoms such as convulsions, paresis or aphasia are added. With the pain there is some local tenderness of the scalp and cranium.

When the tumor is situated in the mid-brain the symptoms are apt to be quite different. There may be the same mental hebetude and tendency to stupor with occasional irritability or childishness, but in addition thereto there will be evidences of more or less profound irritation of the motor centers, yet strange to say, symptoms of interference with speech are not likely to arise when the tumor is located near the speech center; in fact, as a rule, disturbance of speech in cases believed to be tumor are to be regarded as pointing to the pons or medulla and the gray matter at the origin of the cranial nerves rather than to the speech center. The peculiar disturbance of speech consists, in such cases, of a tendency to confluent articulation—that is, to run the syllables together. Jacksonian epilepsy is the chief distinguishing symptom of brain tumor of the central region; when associated with choked disc a mistake in diagnosis is impossible; the tumor is situated at

or near the center, presiding over that part of the body first involved in the spasm. There is frequently a feeling of numbness or prickling in a particular spot preceding a general convulsive seizure—an *aura epileptica*—always felt in the same part; or a general convulsion may invariably begin with a contraction of a certain group of muscles; or the spasmodic contraction may be limited to a few muscles, without unconsciousness, the affected area increasing as the tumor develops. Here diagnosis is easy; or at least such cases *always* demand exploratory trephining; and reference to the picture to be shown when discussing surgical localization—representing the various functions of the numerous gyri of the mid-brain—will show the exact location of the lesion (tumor or other local disease) which can be readily determined by external measurement.

Tumors growing in the posterior parietal region are commonly unaccompanied by marked symptoms until far advanced, though if the supramarginal gyrus be implicated there may be some disturbance of the muscular sense; and word-blindness may appear when the angular gyrus and the inferior lobule are involved. In addition to these there will be the usual disturbances of consciousness and symptoms discoverable in the eye, presently to be mentioned.

Tumors lying near the occipital lobes—so as to press upon or involve the cuneus and first occipital convolutions—give rise to homonymous hemianopsia, while if they exert their influence chiefly in the direction of the angular gyrus, word blindness may accompany the half vision; and if the parietal lobe be also implicated there may be added hemianesthesia and hemiataxia.

Tumors located in the temporal area can not as a rule be diagnosticated (or at least the situation decided upon). The exception is that if the neoplasm be in the left hemisphere and affect the posterior part of the first and the upper posterior part of the second temporal convolution, word deafness will be a symptom which will correctly indicate the point to be exposed by operation.

Tumors of the corpus callosum and of the optico-striate region present a slowly progressive hemiplegia in addition to general pressure symptoms, and are beyond reach.

Brain tumor may give a slow and soft pulse from the general intracranial pressure, or from irritation of the vagus center.

Disturbances of consciousness have already been alluded to, but deserve further consideration. In tumors which grow with great rapidity the stupor or mental hebetude may speedily develop into coma; but in cases more inclined to chronicity a condition of semi-stupor is frequently a prominent symptom—suggesting thrombosis and hence not characteristic of tumor; deep stupor or even coma is quite common in the last stages when the surrounding cerebral substance is becoming softened, or when an anemic condition of the brain is produced by pressure on important blood-vessels or by their involvement by disease progression. In such cases the eye symptoms in conjunction with the peculiar mental trouble will enable the physician to recognize the character of the trouble. But in the earlier stages a different kind of stupor is occasionally met, not dependent upon severe structural changes in parts of the brain other than those immediately involved in the growth; in which cases the somnolent condition is due to general cere-

<sup>2</sup> Illustrating this point, I may mention a case in which I evacuated an abscess involving a large part of the frontal lobes, yet there was no evidence of mental disturbance save a tendency to somnolence.

bral hyperemia; it may or may not be associated with general convulsions. It is liable to appear suddenly, disappearing in a few hours; or it may continue for several days and then subside gradually. Wood records a case of glioma of the brain in the history of which he says: "He had been for some days absolutely comatose, passing his discharges involuntarily and was thought to be dying; a few hours later he walked to the clinic room in a distant part of the hospital."

As already observed, the cranium may be sensitive to pressure as elicited by a gentle stroke of the finger or percussion hammer, or even to pressure with the fingers. The latter I have noted in a number of cases; it corresponds to a circumscribed pachymeningitis with more or less osteitis and is generally indicative of a lesion accessible to the knife.

Migraine is sometimes a symptom of brain tumor; it comes on as a unilateral headache, with intervals of extreme variability accompanied by disturbances of the stomach, tinnitus aurium, considerable dilatation of the pupil of the affected side; in the interval there is apt to be quite an amount of headache, non-migrainous in character.

Chief among the symptoms of brain tumor are those connected with the eye—in fact not at all infrequently the patient first learns of the existence of any head trouble upon consulting the oculist for disturbance of vision. Tumors located at the base of the brain or at the posterior end of the internal capsule or about the optic thalamus—all beyond the possibility of surgical treatment—give rise to most marked interference with sight, while the same is true if they affect the occipital lobes; the manifestations peculiar to tumor situated in the last named region, are such as to enable us to positively locate the disease. Disturbance of the cortical cells of the cuneus, for example, gives a blindness of the outer half of the retina of the same side and the inner half of the opposite side; but if there be homonymous hemianopia with motor paralysis of only one eye, according to Noyes, the location can not be determined.

"Nystagmus, unilateral or double, permanent or temporary, exhibiting itself with other convulsive or paralytic symptoms, indicates cephalic lesion. In general, this will be at the base or on the convexity behind the fissure of Sylvius (region of the angular gyrus). In the former case (when at the base) it will be complicated with paralysis of the motor nerves of the eye or of the optic nerve; in the latter case (when at the convexity) there may be epileptic attacks, hemiplegia, etc., but we can not always venture on an exact localization." (Robini.)

Mydriasis, moderate in degree, may be due to intracranial pressure acting as an irritant to the pupil-dilating center, according to Raehlman, though Leber claims that the mydriasis is sometimes a true paralysis."

Papillitis is frequently associated with brain tumor, generally with dominant infiltration (choked disc). Both optic nerves are commonly affected when the inflammation is due to intracranial growths, though cases of one-sided neuritis have been recorded in undoubted brain tumor; notably cases of Reich, Hughlings Jackson, Pooley, Parinaud and Gowers—in each of which the tumor was upon the side opposite to the papillitis; but usually monolateral papillitis is a condition dependent upon some local cause in the orbit, erysipelas, etc., while bilateral papillitis

will nearly always be found to be due to a tumor in the brain when it can not be traced to injuries of the skull or meningitis—conditions easily recognizable under ordinary circumstances. Cerebellar tumors particularly, tend to the development of papillitis; and the tumor need not be larger than a small cherry to cause the ocular trouble—so say Reich, Edmunds and Anneske. It most often appears late in the disease; indeed most authorities regard its onset as an indication that death will close the patient's existence within a few weeks unless operation is resorted to, but Matthewson has recorded a remarkable case in which it persisted for three years. Choked disc, then, may be regarded as an almost unmistakable evidence of the existence of an intracranial neoplasm, though exactly how it is produced is still an undecided question. Gowers says: "Distension of the sheath may perhaps intensify the process otherwise set up, leading to retention or augmentation of fluid in the lymphatic spaces in the nerve fluid which may in some cases possess an irritative quality." In 1881, Leber suggested that the fluid coming down the sheath provokes the trouble by its chemically irritating properties, and Deutschmann in 1887 injected the bacillus tuberculosis into the cranial cavity of rabbits producing papillitis and vaginal distension, while with innocuous fluids no results followed; as a deduction he maintains that the trouble originates in transmission of pathogenic elements from the neoplasm and that intracranial pressure has little or nothing to do with its production—the latter clause being in entire accord with the belief of almost every prominent ophthalmologist. Picque advances the idea that the trouble is due to the accompanying meningitis, the inflammation being transmitted to the papillæ by continuity of tissue, the intervention of "germs" being unnecessary—a theory supported by the fact that papillitis does not appear until very late in the history of deep tumors, not until the meninges are involved.

Atrophy of the optic disc may also be due to tumor, but not more than one-fourth of the cases—says Noyes—originate in this cause, so its significance is not so great as choked disc. However, it should always be looked for in making a diagnosis.

Hemianopia is usually not a localizing symptom of tumor for reasons already stated; yet it is a valuable factor in the problem of determining whether or not a tumor is operable. I quote from Seguin: "Lateral hemianopia with hemiplegia (spastic after a few weeks), aphasia (if the right side be paralyzed), and little or no anesthesia is quite certainly due to superficial lesion, implicating the motor zone and the gyri lying at the extremity of the fissure of Sylvius, viz., the inferior parietal lobule, the supra-marginal gyrus and the gyrus angularis. Lateral hemianopia without motor, or common sensory disorder, or any other accompanying symptoms, is due to a lesion of the cuneus only, or of it and the gray matter immediately surrounding it, on the mesial surface of the occipital lobe opposite the dark half-fields. Lateral hemianopia with loss of power in one-half of the body, especially if associated with impairment of the muscular sense, is dependent upon a lesion in the inferior parietal lobule and gyrus angularis with their subjacent white substance, penetrating deeply enough to sever or compress the optic fasciculus on its way posteriorly to the visual field." The existence of any one of the groups of symptoms

indicates surgical interference. There are many more symptoms of interest to the neurologist, but none, so far as I know, that can be of use to the surgeon, excepting a few which concern cerebellar tumors; these will be mentioned in the next lecture.

(To be continued.)

### THE ARMY MEDICAL MUSEUM AND THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE.

BY CHARLES SMART, MAJOR AND SURGEON, U.S.A.  
WASHINGTON, D.C.

The Army Medical Museum, which has now a world-wide reputation, had its beginning during the Civil War. Surgeon-General Hammond, in a circular published in May, 1862, announced the intention of establishing an Army Medical Museum, and requested medical officers to collect specimens of morbid anatomy, medical and surgical, which might be regarded as valuable, together with projectiles or foreign bodies removed and such other matters as might prove of interest in the study of military medicine and surgery. Later circulars gave more explicit instructions regarding the collections to be made; and in a short time thereafter an immense amount of material illustrative of gunshot fractures and the lesions of camp diseases was sent to Washington from the field and general hospitals throughout the country. The work of preparing, arranging and cataloguing these specimens was carried on actively under the superintendence of Surgeon J. H. Brinton, U. S. Volunteers who was the first curator; and in April, 1867, the museum was opened to the public in the Ford's Theater building in which two years prior to this, President Lincoln was assassinated. At the same time a small number of copies of an illustrated catalogue was printed for use in the museum and for exchange with other museums and scientific bodies. The entire number of specimens then catalogued was 8,542. At this time also the museum and library received official recognition from Congress by the authorization of certain expenditures in their behalf among the miscellaneous expenses of the Medical Department.

The value of a printed catalogue to a museum is very great, as it is by its means that the collection is made available to scientific students, the majority of whom can not personally examine the specimens, and by diffusing a knowledge of the contents of the museum it leads to voluntary contributions to the collection. A full catalogue of this museum is a want that has long been felt. Partial lists have been published at times, as in 1876 a check list of the preparations and objects in the section of human anatomy for use during the International Exhibition, and in 1880 a list of the anatomic specimens for distribution among army medical officers and anatomic students and correspondents. The Surgeon-General has on several occasions urged the publication of a catalogue; in 1873 and again in his annual reports for 1886, 1887 and 1888. His want of success on these occasions no doubt accounts for the fact that no effort has been made recently in this direction. It is unnecessary to speak of the practical utility of the museum in these columns, for medical men can easily

appreciate this. To Army medical officers it affords a field of study indispensable to the acquirement of the fullest knowledge of the special duties required of them. The illustrations of military surgery and camp diseases contained in it have greatly promoted general professional knowledge on these subjects; and woodcuts of many of its specimens have found their way into works on military medicine and surgery. There is no doubt, however, that the educational value of the collection would be greatly enhanced by the publication of an illustrated catalogue. Much of the material for such a catalogue is already on hand.

As a knowledge of the existence and scope of the museum became diffused, many of the officers of the Army outside of those belonging to the medical department, and practitioners in civil life, sent contributions to it, so that the Surgeon-General was no longer able to speak of "the pardonable pride which he took in the reflection that this important collection had been accumulated through the unaided zeal and industry of the medical officers of the Army." Army officers sent specimens of natural history, stone implements and other objects of archaeological interest, all valuable as objects of exchange with other museums, while civilian practitioners sent specimens more strictly pertaining to the province of the Army Medical Museum. Exchanges have been made with the Smithsonian Institution, the Agricultural Department, the Museum of the College of Physicians, Philadelphia, of the New York Hospital, the Peabody Museum at Cambridge, Mass., the Blackmore Museum in England, the Anatomical Collection at Oxford, England, etc. To the energy and ability of Drs. Woodward and Otis, both of whose too short lives were mainly devoted to the building up of the Army Medical Museum and to professional work associated therewith, the Army Medical Department and the medical profession owe the successful issue of an undertaking which is now a credit to the country.

The Army Medical Museum was housed in the old Ford's Theater for over twenty years. The building was utterly unsuited for this purpose, even had the whole of its space been available for the display of the specimens. As it was, the museum was confined to the third floor, lighted mainly by skylights, the library being packed two and three rows deep on the shelves of the floor below, while the Hospital Records of the Civil War, with the clerks at work on them, occupied the ground floor. The growth of the museum, and particularly of the library during these years manifested the inadequacy of their quarters. In time there came to be no room for even the storage of books and specimens, not to speak of facility of reference or advantageous display. Moreover, the danger from fire was considerable, although the best care was taken by the officer in charge to prevent such a calamity. The building was closed in on three sides by inflammable tenements and sheds on property over which this officer had no control. Besides, the weak walls of the theater, which were cracked and markedly out of plumb on the east, suggested that in case of fire there would be an utter destruction as the walls would assuredly fall. A fire in 1875 in the adjoining buildings emphasized the danger to which the library and museum were exposed and recalled how the Smithsonian Institution suffered in 1865. The damage to the Patent Office in 1877 increased the anxiety for the safety of the collections in the Ford's Theater building so that in

1880 the President of the United States considered the subject of such importance as to embody a recommendation for a fireproof building in his message to Congress. He said:

"The collection of books, specimens, and records constituting the Army Medical Museum and Library are of national importance. The library now contains about fifty-one thousand five hundred (51,500) volumes and fifty-seven thousand (57,000) pamphlets relating to medicine, surgery and allied topics. The contents of the Army Medical Museum consist of twenty-two thousand (22,000) specimens, and are unique in the completeness with which both military surgery and the diseases of armies are illustrated. Their destruction would be an irreparable loss not only to the United States but to the world. There are filed in the Record and Pension Division over sixteen thousand (16,000) bound volumes of hospital records, together with a great quantity of papers, embracing the original records of the hospitals of our Armies during the Civil War. Aside from their historical value, these records are daily searched for evidence needed in the settlement of large numbers of pension and other claims, for the protection of the government against attempted frauds, as well as for the benefit of honest claimants. These valuable collections are now in a building which is peculiarly exposed to the danger of destruction by fire. It is therefore earnestly recommended that an appropriation be made for a new fire-proof building, adequate for the present needs and reasonable future expansion of these valuable collections. Such a building should be absolutely fire-proof; no expenditure for mere architectural display is required. It is believed that a suitable structure can be erected at a cost not to exceed two hundred and fifty thousand dollars (\$250,000)."

A bill authorizing the construction of a fire-proof building passed the Senate in 1883, and was favorably reported from the proper committee to the House of Representatives, but no final action was reached at that session. Ultimately, March 2, 1885, an appropriation of \$200,000 was approved; but as the original plans were based on an estimate of \$250,000 many changes had to be made involving a reduction in size and the omission of ornamentation. The site selected was in the Smithsonian grounds where they are traversed by Seventh Street, having as its neighbors on a line westward the National Museum, the Smithsonian Institution, the Agricultural Department and the Bureau of Engraving and Printing. The museum was opened to the public in its new quarters in February, 1888. On June 30, 1894, it contained 32,269 specimens; of which 12,249 were pathologic, 4,376 anatomic, 1,717 illustrative of comparative anatomy, 12,033 microscopic and 1,894 miscellaneous.

While the success of the museum was assured almost from the first by the inflow of specimens from the hospitals of the Civil War, the progress of the library was slow in its earlier years, and but for the unremitting care and able management of Dr. John S. Billings it would certainly have succumbed to some of the many accidents and harmful influences that are prone to assail the infancy of such undertakings.

The nucleus around which the library has been crystallized was the few books of reference and textbooks on medical subjects that had gradually accumulated in the rooms of the Surgeon-General's office. A catalogue published in 1865 contained the titles of only 1,800 volumes. As stated above, in 1867, certain expenditures were authorized for the library out of the appropriation for the miscellaneous expenditures of the Surgeon-General's Office. Since then, both the library and museum have met with kind consideration at the hands of the Appropriation Committee, the usual sum carried by the Army Appropriation Bill for the former being \$10,000, for the latter \$5,000. For the current year, however, the sum for the library

was reduced to \$8,000. One of the first special efforts of the librarian was to make the library as complete a storehouse of American medical literature as possible. To this end he collected and perfected the files of all the medical journals published in this country since 1798, making an index on cards of the subject titles of all the original articles found in them, for the convenience of those who desired to consult the literature of any special subject. The articles in current medical journals and volumes of transactions were indexed on reaching the library, and the work of completing a card index for all the volumes already accumulated was carried on as steadily and rapidly as was permitted by the clerical aid available for the purpose.

An alphabetical catalogue of authors was published in 1874, when the library contained about 25,000 bound volumes and 15,000 pamphlets. It was then the largest medical collection in this country. Its records show the friendly interest that was taken in its progress and work by physicians in all parts of the country, and testify that even then it succeeded in a most satisfactory way in meeting all the demands made upon it.

In 1887 the work of cataloguing the original papers in medical journals and transactions was completed for all that class of literature that the library then contained; and the classifying of the titles under the proper subject headings and combining them with the titles of books to form a complete index to the collection was also effected. During the previous year some copies of a specimen fasciculus of a proposed Index Catalogue were printed and distributed, in order to obtain the opinion of those competent to judge whether it was desirable that such a work should be published, and if so, to elicit criticisms and suggestions as to the form of catalogue that would be most acceptable and useful. The responses, consisting of letters, resolutions of societies and editorial and critical notices, were numerous and not only favorable to the general plan as proposed, but unanimous in the expression of the opinion that the whole work should be published as soon as possible, it being regarded as of the utmost value to medical writers and teachers not only of this country but of the world. Congress acted favorably on the proposition, and the result is that to-day the medical profession is enriched with a magnificent set of volumes of author and subject titles in a single alphabetical series which will shortly be completed by the issue of the last, the sixteenth volume. The first was issued in 1880, and every year since then, until last year, one volume was added to the set. The completed catalogue will contain about 170,000 author titles, the same number of subject titles of books, and about 525,000 subject titles of pamphlets.

When the first volume of the Index Catalogue was published the library contained 51,500 bound volumes and 57,000 pamphlets. Since then the number of bound volumes has been more than doubled and of pamphlets much more than trebled. The early volumes of the catalogue therefore show only one-half, or less than that, of the present wealth of the library. To remedy this, Congress has shown its appreciation of the work by authorizing the issue of a second alphabetical series, supplementary to the first, which will probably be completed in five volumes similar in size and style to those already issued. Meanwhile, as supplementary to the catalogue, the

sixteen volumes of the "Index Medicus," edited by Dr. Billings and his learned collaborator, Dr. Robert Fletcher, have been of the greatest value to the literary workers of the medical profession. It is greatly to be regretted that this monthly exponent of the progress of medical science may possibly die for want of financial support. Its condition has recently been noticed extensively in the medical journals. As its continuance is of importance to the whole medical profession, the present writer does not see why it should not be in order for the AMERICAN MEDICAL ASSOCIATION to come to its rescue and continue its publication from the office of the JOURNAL. In this way any financial loss would be generally distributed among those directly or indirectly benefited.

The Index Catalogue has given a wonderful impetus to medical literature and education in this country, as it has placed the valuable stores of the library within easy reach of those who are qualified to make use of them. Formerly, when any one desired to become acquainted with the knowledge already acquired by the profession on some special subject, he frequently gave up the effort at the outset as he appreciated the difficulties and oftentimes the impossibility of gathering together the various articles already published on the subject. The bibliography appended to a journal article was often to students of the subject the most valuable part of a contribution. Now, all this is changed. The student has merely to turn to the Index Catalogue and the desired literature is before him, with many hints to guide him in the selection of the volumes that bear especially on his inquiry. The volumes themselves may be obtained by applying through the custodians of public libraries; and in some cases books that can easily be replaced have been sent direct to the applicant on the deposit of a sum sufficient to cover their market value.

It has, however, been found needful recently to impose some restrictions on the loaning of books, particularly of standard authorities and volumes of journals that are in constant demand. As the number of readers in the library has increased, it has more frequently happened that requests for certain volumes could not be complied with on account of their absence on loan. The interests of those who come to the library to prosecute their studies should not be sacrificed for the sake of those who ask the library to come to them. To be able to accommodate both parties, Dr. Billings is endeavoring to procure duplicates of those standard works, journals and transactions that are in general request. Moreover, the wear and tear of years of use is beginning to tell on many of these and to render their duplication needful. Contributions of the character indicated would therefore be of much value; and the writer of these lines trusts that those who have read thus far will make a note of this and aid the library in this desirable extension of its field of usefulness. Its friends need have no hesitancy in duplicating works already on hand, as the spare copies can always be made of use in effecting exchanges.

It is time, however, to say a few words concerning the present quarters of the library and museum. The building is of red pressed brick, E-shaped, and severely simple in style. The main building fronts on B Street, the wings project into the mall. This is a mistake, as all the other public buildings in the vicinity front on the park. Hereafter when it becomes

needful to enlarge the establishment this mistake will no doubt be rectified. The main building is 125x55 feet, the wings each 60x131 feet. Under both is a basement eleven feet high which affords magnificent storage rooms.

The ground floor is traversed by a central corridor, clean, white, smooth and unadorned, on either side of which are doors leading into rooms of various sizes. On the western or left side of the entrance are rooms occupied by clerks of the Record and Pension Office of the War Department. On the right are the lecture rooms and sanitary laboratory of the Army Medical School, the work room of the pathologist and the chemical laboratory where guard is kept over the purity and strength of the medical supplies furnished to the Department. One of the rooms on this floor is given up to specimens of syphilitic disease unsuited for display in a museum open to all comers; another has been fitted up recently with various forms of stretchers, wheeled litters, cacolets, travois and other means of carrying sick or wounded men. Opposite the entrance a wide stairway of iron, carpeted with thin rubber, makes a semi-circular sweep to the second floor. The corridor of the main building on this floor opens on the west into the museum hall and on the east into the library, the rooms on either side being used by the clerical force of the latter. One large room adjoining the library is fitted up as a reading room for those making personal use of the books, and has on its shelves such works as are in everyday request. The floors throughout the building are of brick between rolled iron sheeting.

The rooms on the third floor are occupied by those connected with the work of the museum. The bacteriologic laboratory on this floor is well outfitted and has an excellent northern exposure for microscopic work. Such of the attics as are not required for photographic work are used as storerooms.

The whole of the eastern wing from the second floor level to the roof is occupied by the library. This fine hall, thirty-one feet to the eaves and forty-seven feet to the ridge, is lighted by high windows and skylights in the risers of the ridge. The south end of the hall near the entrance from the corridor presents a large floor space which supports only a few desks, chairs, revolving book stands and large tables for the convenience of visitors in consulting atlases and other large works of reference. On three sides the whiteness of the walls between the window spaces is relieved by large oil paintings of some former Surgeon-General of the Army,—Tilton, Lovell, Lawson, Finley, Barnes and Crane, with portraits also of Bichat, John Hunter, Morton and Physick, and many photographs and engravings. On the fourth, the north side, this clear space is closed in by what looks at first sight like a solid wall of books in red leather bindings. On closer inspection the wall becomes resolved into a three storied framework of perforated iron, each story seven and a half feet high and extending along the length of the wing to its northern wall. Narrow iron stairways permit of communication between the stories and narrow corridors between the sections of the structure, each section being fitted with adjustable shelves of hard oak, filled with books or with file cases containing pamphlets. The estimated capacity of the library is 179,000 volumes. On June 30 of last year there were supported on its shelves 114,567 bound volumes and 183,778 unbound pamphlets and papers. The former

comprised 72,090 medical works, 33,297 volumes of medical journals, 4,913 of transactions of societies, 1,663 of theses and 2,604 of pamphlets. The latter consisted of 56,218 theses and 127,560 pamphlets. The binding of these into volumes depends on the means available. In 1893, 630 pamphlets were bound into 128 volumes and last year 2,802 into 343 volumes.

These books are all devoted to medicine and its collateral branches. No purchase is made for the library of books belonging to general or miscellaneous literature. It has all the costly illustrated medical works and anatomic atlases. It has also a valuable collection of the medical classics and a number of the rarities and curios of medical literature; but the aim has ever been to make it a storehouse of the medical thought of the present day rather than a collection of works that are of interest only from a historical point of view. The library is by far the largest of its kind in the world. This is gratifying to us; but we can take a much greater pride in the thought that of all such libraries it is the one which is most available for and most used in the current work of medical progress.

The museum hall in the west wing has a floor and cubic space equal to that of the library, but the two halls differ widely in general appearance. The contents of the museum are disposed in open order as contrasted with the compact shelves, tiers and sections of the library. The specimens are arranged in glass show cases, each about twelve or thirteen feet long, two and one-half feet wide, and eight feet high, which project into the body of the hall from the side walls, but with ample space for light and movement between adjacent cases. On the third floor level is a gallery which projects beyond the ends of the show cases below, but does not interfere with the light from the skylights in the ridge. The gallery is reached by a stairway at each end of the hall, as well as by a door opening from the corridor of the third floor of the main building. Some flags are draped from the face of the gallery, conspicuous among which is the hospital flag of all the armed nations of the world, the Red Cross of the Geneva Treaty.

The first thing the visitor must do on entering this hall is to record his name on the visitor's book. In 1893, 85,000 persons did this; last year 50,000. Most of these were merely sightseers; but the interested and appreciative student is always among them.
